The question strikes one as to whether this peculiar horse-raddish odour has an attraction for the weevil that destroyed my fungus, for we find that it certainly, I ought to say presumably on account of that odour, attacks the host, even in the living state of the latter. Everybody who knows the habit of the *Moringa pterygosperma* can call back to memory the gum-studded stem of this tree marked with burrows and furrows clogged with the millet-seed sized globules of the weevils' excreta bound up in innumerable chains with flocculent fibres net minks a cobweb. Does this weevil find any special charm in the odour which the fungus inherited from the *Moringa*. * * * The point is worthy of investigation, and I commend it to the careful study not only of those who are interested in the study of fungi, but also of those who watch the habits of the insects and molluscs which destroy our plant life.

* So in Ceylon, but the pods make favourite curries here.—*Ed. T. A.*

Correspondence.

To the Editor.

THE TEA PACKING PAPER.

Billiter Square Buildings, London, Aug. 27, 1891.

DEAR SIR,—Since writing you on 13th instant my attention has been drawn by the Brokers to a break of tea from Laurence estate, lately arrived, packed in the lead paper linings. The quality appears to have been entirely preserved, and is reported as particularly brisk and good.

I mention this fact, as doubtless planters will be looking out for results, as a good many have been experimenting with various sized breaks. I may mention that we have completed arrangements with Messrs. Pierce, Leslie & Co. for the agency of the articles for Southern India and Malabar coast, and within the last few days we received a large quantity of orders for immediate transactions.—Yours truly,

J. M. MAITLAND KIRWAN & Co.

[This following is the notice referred to, which occurs in Messrs. Wilson, Smithett & Co.'s Circular:—
"A break of Laurence Pekoe Souchong packed in the new, patent paper lining recently came under our notice, which on inspection, we found to be in excellent condition."
Ed. T. A.]

CEYLON PLANTERS' TEA COMPANY OF
NEW YORK.

Colombo, Sept. 14,

DEAR SIR,—We have pleasure in sending you herewith extracts from correspondence recently received from New York giving particulars of some of the efforts which the Ceylon Planters' Tea Company are making to push the sale of Ceylon Teas in America.

This correspondence will doubtless be of great interest to those of your readers who are shareholders in this Company as well as to others who desire to see fresh outlets for the sale of Ceylon Teas.—Yours faithfully,

p. pro. DARLEY, BUTLER & CO.,
JAMES F. HEADRICK, Agents for Ceylon.

Extract from letter dated New York, 11th August, 1891, from Mr. S. Elwood May to the Hon. J. J. Grillinton.

"I have just returned from Chicago where I minutely investigated the prospects of the fair, as well as going all over the site appropriated for its use.

I have requested the Bureau of the Exposition to mail to Ceylon its literature, &c., which will save any necessity for my going into details.

After having visited most of the large world fair and spending two months at our centennial fair held at Philadelphia, to which I was appointed, and being fresh from the Naval and German exhibitions in England, which I also carefully studied, I can state that the 'World's Columbus Exposition' will be the largest fair ever held anywhere.

I know you will rejoice with me in the fact that I have been enabled through the result of my London work and your kind aid in Ceylon to make the arrangement with Mr. Arkell indicated in copy of his letter to me herewith enclosed for your information.

In considering the great value of this contract do not lose sight of the fact that this will distribute the stock of our company among at least 1,500 of the leading newspaper owners all over the country whose interest at once must be to aid in making this stock valuable.

As a suggestion to the planters of Ceylon to make this Chicago exhibit somewhat on the lines of India, China and Japan, they should each contribute a certain quantity of tea which could be sold here and proceeds of sale added to the sum voted by the 'Tea Fund Committee.'

Kindly bear in mind that the smallest exhibitor intends to make the effort of his life at the Chicago fair."

Copy of letter from W. J. Arkell to the President of the Ceylon Planters' Tea Company referred to in above letter.

Mr. S. Elwood May, President, Ceylon Planters' Tea Company, New York.

DEAR SIR,—In regard to our conversation of this morning, I will state that if your company desires me to place \$50,000 worth of advertising with the representative papers of this country within a period of three years, I will do it for \$100,000 with the understanding that if I desire to place \$150,000 more of advertising to be covered in three years that I am to receive an additional \$300,000 worth of stock for this advertising.

It is understood that you will leave the advertising to my discretion, since being such a large holder of stock I would want to place the advertising where I believe it would do us the most good.

If this meets the favourable consideration of your board kindly notify me and oblige.—Yours truly,

(Signed) W. J. ARKELL.

TEA PREPARED AT DIFFERENT TEMPERATURES.

Sept. 14th.

DEAR SIR,—Enclosed are the results of some experiments I have been making as regards tea fired at different temperatures, etc. The *A lot* was fired up in imitation of chula firing. You will note, as the temperature increases, flavour decreases. *B lot*.—In this, the same as above flavour decreases as temperature goes up. Of the two methods of firing with No. 1 Siroccos, I prefer the firing up, viz., placing the wet leaf in the hottest place first and finishing off at the top. It requires on the whole a rather higher temperature than the old method, but the damping of the sir from the wet tray under, very considerably reduces the temperature to the upper trays. No doubt the tea made this way is on the whole better than firing down, as the fermentation is checked at once and there is no staving in the upper tray, as is the case when you fire down at a low temperature.

Unfortunately with our present machinery we cannot use the low temperature which secures the aroma and flavour, unless the draft can be very much increased as Mr. Davidson speaks of doing; but he requires a fan driven at high speed. This requires power, which is a great consideration, where both water and fuel are short. We can get electric motors which will give us all the power required from our rivers which run at the foot of most of our valleys; then again this necessitates a great expense. For No. 1 Siroccos, making the chimneys higher would increase the draft, so enabling us to fire at a lower temperature and help in a great measure to improve the make of our teas. The lower the temperature we fire at the better will be our teas; for this we require air moving at high speed to keep the volatile oils in.—Yours,

ENQUIRER.

EXPERIMENTS REFERRED TO.

ALL FIRED IN A NO. 1 SIROCCO.

Results of firing at six different temperatures in a No. 1 Sirocco, wither fairly even; rolled 1 hour and 30 minutes without sifting.

Sample No.	Temp. of Stoveco.	A. FIRED UP.		Remarks.
		Time in drying.		
1	210°	40 to 45 mts.		Bright infused leaf, pungent, flavoury, good aroma, fairly strong liquor.
2	240°	25 to 30 "		Bright infused leaf, malty liquor and flavoury, fair aroma, good body and fair strength.
3	290°	20 to 25 "		Infused leaf, same as No. 2, malty liquor, more body and strength, <i>no flavour.</i>
B. FIRED ORDINARY WAY.				
1	200°	1 hour		Infused leaf, bright but darker than A 1, liquor pungent, flavoury, good strength & body.
2	230°	30 mts.		Infused leaf, same as No. 1, but lighter, less body and flavour, but more strength.
3	260°	25 "		Infused leaf, same as No. 2, fair strength and body, little or <i>no flavour, amount equal in all.</i>

A. No. 1 creamed slightly; No. 2 good light milky cream; No. 3 creamed thick and darker than No. 1 and 2.

B. No. 1 light cream; No. 2 same as No. 1, but darker; No. 3 thick dark cream.

The above teas were fired on a fine sunny day, with the thermometer in the factory standing at 85°.

THE LOCAL VS. THE LONDON MARKET FOR TEA.

Central Province, Sept. 21st.

Sir,—The question "Does it pay better to sell tea in the local market than ship it to England?" has been so frequently asked amongst planters that the following facts may interest some of your readers.

A, B and C are three different properties under my supervision. The tea leaf from all three is manufactured on A as if it all belonged to A. The tea is all carefully bulked and packed twice a month in the slack season, and weekly, as a rule during the busy months.

The breaks despatched averaged 4,541 lb. to A, 3,688 lb. to B, 2,819 lb. to C, and consigned to the respective agents of the three properties. A's teas were shipped and the gross average of sales in London was 10-15d per lb. If we knock off 2d according to the Planters' Thumb Nail Tea Price Table we have 8-15d at 1s 6 1/2 the average rate of exchange at 8 ms., July 1890 to August 1891, which shows 1d = 5-413c. × 8-15 = 44-36c. for A's tea. B's tea sold in local market at 47-03c. and C's for 49-56c. average.—Yours truly,

THE SUPERINTENDENT.

PEPPER GROWING IN SUMATRA.—The cultivation of pepper in the Lampong districts (Southern Sumatra) is constantly increasing. The output in 1890 is estimated at 50,000 piculs (one picul equals 133 1/2 lb), and it is calculated that, at an average price of 48s 6d per picul, over 125,000l in cash has been received by the combined pepper-growers for their produce. The Dutch Indian Government are also endeavouring to extend the pepper industry in Bautam (Western Java).—*Chemist and Druggist.*

THE DECLINE OF THE FOOCHEW TEA TRADE.—The *Foochow Echo* of 12th Sept says:—As further evidence of the depression in native trade here scores of shops and houses in the city and suburbs are noticed to be untenanted, many of them being offered for sale at half the original cost. A well-informed native attributes this solely to the rapid decline to the Tea trade, pointing out that for the last three or four years it has, while falling off, been at the same time unprofitable, and that those engaged in it have had no money to spend. This is confirmed by others, and so many were connected with the trade one way and another that we can quite believe it. The settlement next

week (the 12th and 13th days of the 8th moon) will, it is said, not pass by without a great deal of trouble to very many, and those who are able to tide it over will have a disagreeable time to look forward to next settlement, the China New Year, unless some great change comes about in trade in the meantime. The once flourishing Foochow is at present in a very bad way.

WYNAAD.—Coffee promised to yield a bumper crop, but the planting community is growing despondent, as leaf disease is playing much havoc, and berries drop largely; nevertheless, the crop will not be as bad as that of last year. But the planters would do well to keep a sharp look-out on some well known Mops in the far south, who own some Paniars nominally for cultivation, but really for stealing coffee. These Mops know where to please and grease, and of course, pass off as Masaraths and Khan Sahibs.—*M. and T. Spectator.*

CEYLON TEA FUND.—As a Kandy correspondent hinted last week, the Tea Fund Committee transacted some important business at its meeting on the 18th instant, as will be seen by the report of the proceedings on page 274. It is satisfactory to learn that Government is to grant a sum of Rs50,000 towards the representation of Ceylon at the Chicago Expository, and that the Tea Fund has set aside Rs30,000 for the pushing of Ceylon tea there. We hope that this will lead to a large demand for our teas in the States. What the purport of the letters from Messrs. W. Mackenzie and Sheriff was, we can only guess; and we hope that some means will be found of satisfying both parties in the Tea Kiosk controversy.

It is understood that the Secretary of State has ordered an experiment to be made in India with the *Lathyrus Sylvestris*, or flat pea, a wild plant of the same order as Peas or Vetches, but which has been discovered to be a valuable forage production, by sowing some lands in Oudh and the North-West with the seed. Successful fodder that will grow and thrive in poor soil under such conditions as are now harassing some of our Southern districts would be a boon to the impoverished tenants and starving cattle of the distressed centres, the value of which it would be impossible to overrate. It is claimed for this new plant that it is especially suitable to a dry climate, as it can resist the most unusual drought; it requires no manure, will grow on the same soil year after year, and will flourish on waste stony land where nothing else will, and improves rather than deteriorate the soil. It has been successfully tried in Ireland, Germany, Australia and South Africa, and if all that is said of it is true, should soon become much sought after in this land of impoverished tenantry and maderiel cattle.—*Indian Agriculturist.*

A CALIFORNIAN paper says—"The liquid in which the State Board of Trade has so successfully preserved fruit for exhibition purposes is prepared as follows:—Thirty gallons of filtered water are placed in a barrel end; on the water is placed in a tin pan containing 25 cents worth of sulphur. The sulphur is set on fire, and the top of the barrel is covered with a piece of oilskin, so as to retain the fumes. When the sulphur ceases to burn the covering is removed, allowing the supply of oxygen in the barrel to be renewed, and after stirring the water the sulphur is again set on fire and the top of the barrel is again covered. This operation is repeated until the sulphur will no longer burn, when the water is ready for use. Not only are fresh fruits preserved in this water, but where decay has set in it is completely checked, and withered fruits have their plumpness and colour restored. All the fruit in 'California on wheels' has been treated in this manner, and there are jars of fruit in the rooms of the Board that were prepared over a year ago, the fruit still appearing as if but plucked from the tree."—*Indian Agriculturist*, Aug. 29th.

NOTES ON PRODUCE AND FINANCE.

INDIAN AND CEYLON TEAS IN AUSTRALIA.—It is clear that Indian and Ceylon teas are making rapid headway in Australia. China is losing the market. The quantity of tea received from Foochow in the twelve months was fifteen-and-a-quarter millions of pounds, against twenty-one and twenty-four millions during the two preceding years. Meanwhile the shipments from India and Ceylon to Australia in the twelve months are given as:—From India, 4,800,000 lb.; from Ceylon, 2,900,000 lb.; total, 7,700,000 lb. The *Melbourne Argus*, commenting on this, says—"There can be no doubt that not only China, but also India, has much to fear from the competition from Ceylon. The well-cured Ceylon teas are certainly most attractive, being remarkably flavoured, with good strength. Ceylon teas, however, have one serious disadvantage, and that appears to be their inferior keeping qualities; and, judging from the present year's receipts, this trade is certainly 'the jam tart trade' to tea. They are all better sold fresh than stale and flat, which, in many instances, from inferior manufacture, they soon become. There is, however, a somewhat better demand for choice Ceylon Pekoes, and it only requires time to educate the public taste for the demand to be good for choice teas from both Calcutta and Colombo."

TEA RE-PACKING IN BOND.—The following order has been issued by H. M. Customs. "The Board authorises inspectors of districts to allow remnants of blending and re-packing operations in tea to be used without application to the Board in subsequently blending operations, provided that such remnants do not exceed the limits laid down in Port Order 50, 1889."

BOARD OF TRADE STATISTICS.—The board of trade returns for August show that the imports of China teas are still falling off, while those of India and Ceylon are increasing, and this holds good as to the consumption also. The deliveries out of bond of articles liable to duty for home consumption is generally taken to indicate the prosperity or otherwise of the wage-earning portion of our population, and their capacity for absorbing the various beverages which are used in daily life. On these there has been a decline during the month in coffee, and an increase in chicory, cocoa and tea. There is an increase in all for the eight months of the present year as compared with the corresponding period last year.

COFFEE CULTURE IN JAVA AND SUMATRA.—The annual report on the finances of the Netherlands (India) deals with the subject, and the Minister for the Colonies fully recognises the importance of the question, but he points out that any proposal to introduce new systems must receive careful consideration, there being always the risk lest any modification of an existing system may result only in a sacrifice of certain interests in order to acquire other no certain advantages. It is furthermore pointed out that there is no product which in any immediate future can be looked for to replace coffee as a source of revenue. Any ill-considered change might increase the burden of indebtedness and at the same time cripple the administrative powers of the Government. The future, however, is stated not to be so dark as has been represented. Notwithstanding the coffee plant dense the harvests in 1888 and 1889 were fairly good ones, and it is mainly on account of the unpropitious weather that that of 1890 has been so deficient—a very small amount of coffee having, in fact, been collected. The prospects for 1891 at the time this statement was drawn up were not unpropitious, and so the gloomy anticipations which had been indulged in quite unjustifiable. In dealing with the financial question generally, Baron Mackay again alluded to the impossibility of finding any substitute for coffee as a source of revenue. It was fortunate, he said, the present deficiency from this source was made up for by the results of previous years of prosperity. Had it not been for this a recourse to a loan would have been inevitable. He, however, fully recognised the gravity of the situation, and the necessity for economy, holding out no prospect of

being able to raise any considerable sum from new taxes. At the same time, he declined to admit that the prospect was as unfavourable as it appeared to be in some quarters, showing by a comparison of 1888 with 1891 that the total expenditure is considerably less in the latter, although the amount included in the estimates for productive works is higher. It is not, however, denied that the relation between income and expenditure unconnected with produce has become less favourable than formerly. This, it may be presumed, is principally on account of a diminution of income from land rents and from the opium monopoly. Much is hoped from a more prosperous coffee harvest to redress the balance of income and expenditure; at the same time, it may be foreseen that even to carry out productive works it may be necessary to have recourse to a loan.—*H. and C. Mail.*

TEA FIRING AT HIGH AND LOW TEMPERATURES.

The letter of "Enquirer," on page 281, giving the results of some very careful experiment, in firing tea at various temperatures, is well worthy of attention from planters and tea-merchants. The general conclusions are entirely in favour of the principles recently so emphatically enunciated by Mr. Davidson, of Sirocco and "down-draft" fame. All the experiments gave the same result: at the high temperatures, from 270° to 390°, all special tea flavour and aroma had disappeared, and a rich, malty taste and smell came instead; not the peculiar violet flavour desiderated. A drying machine to fire at a low temperature, therefore, would be a great gain to planters. Such machines are provided in Mr. Davidson's "down-draft sirocco" and Mr. Jackson's "Britannia," excellent both, but both expensive. The claim for Mr. Jackson's machine, however, that it is an effective witherer as well as a good drier, is an important consideration in facing the first cost. We cannot help quoting from the private letter of a correspondent as to the general conduct of tea planting and manufacture:—

"What we really require is that our teas should be made on some certain basis, and this can only be done by the whole series of manufacture, growth, pruning, as to season &c., worked out in different districts, by an analytic chemist. Like beer and nearly all the principal food manufactures at the present day, all under guidance of the analytic chemist."

A CHINESE TEA MERCHANT AT HOME.

The *Independent* [American paper] says that the following glimpse of the domestic life of a Chinese millionaire is given by one of two British young ladies, who recently, and without male escort of any kind, made a tour round half the globe. The gentleman whose home was thus laid open to view was a successful tea merchant at Canton, possessing a fortune estimated at thirty-five millions:—

After walking ten minutes from the landing stage we reached a massive gate opening on a large court. Several men, apparently servants, were lounging about, and to one of them the English friend who had met us on our arrival at Canton, gave his card, on which he had pencilled a few words in Chinese. With this the man went off, and while waiting his return, we curiously examined a handsomely decorated covered chair, evidently very heavy, which was standing in the court, with four coolies in attendance, all dressed alike in livery. Our friend said it was a mandarin's chair, and that probably the mandarin was calling on Mr. Howqua. The servant soon returned and marshalled us across the court, along passages, through rooms, and round corners while we gazed on the mysteries of Chinese architecture. As our captain had said, "a Chinese house is a meaningless muddle from beginning to end." At last we entered another court, smaller than the first, with some fine vases

standing about, and on this opened the room where Mr. Howqua was. He ran to meet us, beaming. He was a little, wizened, yellow Chinaman, with high cheek bones, oblique eyes, a pig-tail, and a little silk cap on his shaven crown. His dress was as plain as possible, with not a sign of wealth about. This surprised us, for, in the street at least, the dress of the richer Chinese is rich and tasteful. He spoke excellent English, and not that dreadful mixture called "Pigeon English" which seems the only medium of communication between Europeans and Chinese. As we were each introduced in turn, he bowed low, and *chin-chinned* Chinese style. Then, in deference to our Western ideas of politeness, he shook hands—rather a difficult proceeding, owing to the length of his finger nails. To *chin-chin* you close each hand separately, then, putting both together at the chest, gently shake them up and down and say "chin chiu." After all this ceremony had been gone through, we became conscious that another Chinaman, sitting on one of the great chairs, was looking at us much in the same way as a child for the first time at the Zoo looks at a monkey. We looked at him, too, for he was a great personage, no less than the mandarin and the Chief Secretary of the new Viceroy. It was his chair we had seen outside. He was as different from our host as possible—tall and very stout, and magnificently dressed in brocade and furs, with the mandarin red button on the top of his hat and a heavy gold chain round his neck. He spoke no English, but rose and *chin-chinned* with solemnity when he was introduced, while we made as deep a bow as we could. As conversation went on he seemed quite content to sit and survey us. He may have seen English women in the street, but it is very probable he had never met any before.

THE DRAWING ROOM.

The large and lofty room was furnished with tables, high square stools, couches, and arm chairs of heavy black wood, all elaborately carved. The couches as well as the chairs had cushions of red silk, and were like old-fashioned settees. Each couch was divided into three, like a first class railway carriage, but the padded arms of the carriage were here small tables. Some handsome lamps, of the shape seen in all Chinese pictures, were hanging from the ceiling, and there were some ornaments which even our inexperienced eyes recognised as of great value; but on the wall were hanging some shabby photographs in still shabbier gilt frames. The whole front of the room was open to the dreary little court. The floor was of earth, and the effect was cold and cheerless.

HOW TO DRINK THE TEA!

A servant brought the tea in handless cups of egg-shell china. Each cup, being supplied with its own pinch of tea, had a small saucer at the top to keep back the leaves, and a large saucer at the bottom. The problem was how to get at the tea. We wished to take it correctly, according to the Chinese fashion, and show that we had at least a smattering of civilisation. No doubt the Chinese find it as objectionable to see any innovation on the established fashion of sipping tea as we do to see a man eating peas with his knife. So we watched the mandarin. He placed his thumb under the large saucer, his second finger above the small saucer, and, raising the cup and both saucers, contrived, by some slight of hand, to empty his cup. This was too difficult for us. We gave it up. We removed the small saucer. Even then it was difficult to convey the beverage to one's lips, for, as I said before, the cup was without a handle, and was moreover exceedingly hot. In spite of the absence of sugar and cream and the number of tea leaves we swallowed, the tea was delicious. On our praising it Mr. Howqua presented each of us with a silver paper-covered jar of it to take away with us. We learned afterwards that this particular tea never reaches England. It is all sent to Russia, where it costs, in English money, over a guinea the pound.

NOISY DISPLAY OF JUVENILE PROFICIENCY.

Tea being over, Mr. Howqua took us to a room

where seven of his sons (of ages, apparently, from nine to fifteen) each at a separate desk were learning their lessons. They were like miniature men, with their pig-tails, and little silk caps, and came forward with expressionless faces to shake hands with us. To the mandarin they bowed—almost to the ground—and he returned the salutation with profound ceremony. At a word from their father they let us hear how well they could read; but as they read all at the same time, each boy at the pitch of his voice, and as they were all (so far as we could make out) reading different words, the effect was somewhat startling. Then the great man took his departure, and we were shown over the house. This was a complete puzzle to the uneducated Western mind. Privacy seemed to be the last thing thought of. Comfort there was none. But the rooms were full of beautiful objects, carvings, vases, beaten work in gold and silver and embroideries which must have been worth large sums of money. In one room was

ONE OF MR. HOWQUA'S WIVES

with several maids in attendance. She was quite young, and might have been made of wood for all the interest or expression there was in her face. As she *chin-chinned* she looked like a big mechanical toy. Her cheeks were thickly plastered with red and white paint, and her hair, stiffened and stuck out in the Chinese fashion, was adorned with a long gold pin. Another room was used as a private chapel, containing an altar, before which joss sticks were burning, and was hung round with portraits of his ancestors. Mr. Howqua pointed out the portraits of his great-grandfather and grand-father, and there were others of much earlier date. But the great joy of our host's heart were two rooms furnished in European style—one as a dining-room, the other as a smoke-room. In the dining-room the table was laid for dinner, and the sideboard was laden with different kinds of wine-glasses. Here, we are told, Mr. Howqua gave dinner parties to his European friends. After we had seen through the whole place, our kind host insisted on our going to see his mother. She lived at a few minutes' distance, but in the same great enclosure—which might be called the grounds—belonging to the Howqua Mansion.

THE DOWAGER AND HER DWELLING.

Her house was so like the houses seen in Chinese pictures that as we neared it we seem to be realising a dream. Built on the edge of a lake, which was covered with lotus leaves, it had little staircases, terraces, covered roofs, and wide verandahs, into which the whole front of the house opened. There, too, were sitting the Chinese ladies, with trays and jars. Old Mrs. Howqua, who was very, very old, had probably been told that we were coming to see her, for she was seated in state on a low chair placed on the verandah, with her women grouped behind her. She wore on her head a black velvet coil, very like the Mary Stuart cap, edged with pearls, and with one enormous pearl in the centre. Her tiny feet, of which she seemed very proud, were just seen below the edge of her skirt, and those feet gave us quite a shock. Two days before I had bought a pair of Chinese lady's shoes, but could not believe that any woman could wear such a small size. Mrs. Howqua's shoes, however, were quite as small as those I bought, but it is probable that her feet were exceptionally small.

THE TEA TRADE AND THE DUTY.

For the edification of those who like statistics, we supplement our remarks of last week on this subject with the full report of the Commissioners of Customs so far as it relates to tea. In the year 1890-91 the tea duty was reduced from 6d to 4d a lb. It may be useful here to record the steps by which the duty on this article has been reduced from between 2s to 3s per lb. to its present rate of 4d.

In 1835 the duties in force stood as follows:—

	Rate per lb.	Revenue realised.
1835.—Bohea.....	1 6	£3,832,872
Congou Twankay, Hyson skin, Orange Pekoe and Campti	2 2	
Souchong, Flowery Pekoe, Hyson, Young Hyson, Gunpowder, Imperial and other sorts unenumerated	3 0	
These different rates of duty were abolished in 1836, when the rate was made uniform. The changes then and subsequently made have been:—		
1836.—All sorts of Tea ...	2 1	
1840	2 1	3,472,864
1853	1 10	5,663,791
1854-5	1 6	5,126,317
1855-6	1 0	5,802,066
1857-8	1 0	5,459,698
1863-4	1 5	4,554,475
1865-5	0 6	2,569,817
1890-1	0 4	3,416,802

The extent of the loss which the revenue has sustained by the reduction in duty of 2d. a lb., when compared with the preceding year's receipt, is not so great as had been anticipated, the increase of consumption having been very marked. The gross revenue from tea in 1889-90 was £4,490,695. Last year it was £3,416,802, an actual loss of £1,073,893. The effect of the reduction of duty upon consumption has been as follows:—The quantity of tea on which duty was paid in 1889-90 was 179,620,000 lb. In the year under review the quantity has turned out to be 202,633,000 lb., an increase of 23,013,000 lb. Thus the actual gross quantity cleared for duty increased by 12.8 per cent. But this result does not give the true state of the case. The Budget statement was made on April 17th; but the reduction in duty did not actually take place until May 1st. Early in January a large section of the tea trade appeared to have formed the idea that some portion of the surplus which it was known would be at the disposal of the Chancellor of the Exchequer would be devoted to a reduction of the rate of duty. This anticipation soon began to influence the quantities taken out of bond for consumption. Thus in January the clearances for duty showed a decrease, as compared with the corresponding month of 1889, of 913,551 lb., in February of 1,129,837 lb., in March of 3,957,086 lb., and in April of 10,040,461 lb. Altogether the decrease in the quantity on which duty was paid amounted, for the first four months of 1890 to 16,040,935 lb. To this extent dealers supplied the public wants out of their duty-paid stocks which were depleted in a corresponding degree. When the lower rate of duty came into force on May 1st the exhausted stocks were quickly filled up, the clearances in May, 1890, amounting to no less than £33,095,211 lb. against 16,527,162 lb. in May, 1889, an increase which more than made good the depletion in duty-paid stocks above mentioned. But this replenishment of stocks fell entirely within the financial year 1890-91, while the revenue of the preceding year had suffered to the extent represented by six million lb. of tea held back from duty. For the sake of clearness we give a comparative table showing the quantities of tea taken out of bond in the months of January, February and March in 1888, 1889, and 1890:—

	1888.	1889.	1890.	1890 compared with 1889.
January	16,750,669 lb.	17,144,627 lb.	16,201,076 lb.	913,551 lb.
February	15,254,685	14,429,410	13,299,573	1,129,837
March	14,790,845	14,996,038	11,038,952	3,957,086
Total of three months	46,796,199	46,540,075	40,539,601	6,000,474
April	15,895,873	14,768,871	4,728,410	10,040,461
Total of four months	62,692,022	61,308,946	45,268,011	16,040,935

The effect of the reduction of duty upon consumption cannot, therefore, be seen until allowance has been made for these deferred duty payments. In this case the duty payments do not represent the normal conditions of clearance for home consumption, which can only be arrived at by deducting the 6,000,474 lb. from the clearances of 1890-91, and adding them to the duty clearances of 1889-90. But taking the eleven months since May 1st, 1890, during which the lower rate of duty was actually in force, to March 31st, 1891, the quantity of tea cleared for home use amounted to 197,905,000 lb. From this must be deducted the estimated "held back" tea of January, February, March and April, amounting to 16,000,000 lb., which gives the normal clearance for home consumption for the eleven months as 181,905,000 lb. Comparing this amount with the quantity cleared for duty in the same eleven months of 1889-90, viz.: 164,852,000 lb. (of which latter total we must first add six million lb. properly belonging to the consumption of January, February and March, but only cleared in May), we have the following result:—

May 1889 to March 1890 inclusive.....	170,852,000
May 1890 to March 1891 inclusive.....	181,905,000
Increase in 1890-91.....	11,053,000
being an increase of consumption at the rate of 6.5 per cent. The subjoined figures show the consumption per head of the population:—	

	lb. per head.
1886-87	4.92
1887-88	4.97
1888-89	4.94
1889-90	4.91
1890-91	5.14

The calculation for the last two years shows the effect of the change of duty, and allowance being made for the "held back" tea. The actual quantities of tea on which duty was received for 1889-90 and 1890-91 would show a consumption of 4.75 lb. and 5.30 lb. respectively per head of the population. The process of consumption of Indian and Ceylon teas in substitution for China and other teas still progresses, the percentages for the past year being 70.9 to 29.1 respectively, as against 68.3 to 31.7 respectively in 1890-90 —H, and C. Mail.

EGGS AS FOOD.

Eggs, at average prices, are among the cheapest and most nutritious articles of diet. Like milk, an egg is a complete food in itself, containing everything necessary for the development of a perfect animal, as is manifest from the fact that a chick is formed from it. It seems a mystery how muscles, bones, feathers, and everything that a chick requires for its development are made from the yolk and white of an egg; but such is the fact, and it shows how complete a food an egg is. It is also easily digested, if not damaged in cooking. Indeed, there is no more concentrated and nourishing food than eggs. The albumen, oil and saline matter are, as is milk, in the right proportion for sustaining animal life. Two or three boiled eggs, with the addition of a slice or two of toast, will make a breakfast sufficient for a man, and good enough for a king.

According to Dr. Edward Smith, in his treatise on "Food," an egg weighing an ounce and three quarters contains 120 grains of carbon and 17½ grains of nitrogen, or 12.25 per cent of carbon and two per cent of nitrogen. The value of one pound of eggs as food for sustaining the active forces of the body is to the value of one pound of lean beef as 153½ to 9000. As a flesh producer, one pound of eggs is about equal to one pound of beef.

A hen may be considered to consume one bushel of corn yearly, and to lay 10 dozen or 15 pounds of eggs. This is equivalent to saying that three and one tenth pounds of corn will produce, when fed to a hen, five-sixths of a pound of eggs; but five sixths of a pound of pork requires about five pounds of

corn for its production. Taking into account the nutriment in each, and the comparative prices of the two on an average, the pork is about three times as costly a food as the eggs, while it is certainly less healthful.—*Boston Journal of Chemistry.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

LONDON, Sept. 5th, 1891.

ANNATTO.—After showing more firmness recently, this article appears to be again falling into its former neglected state. Good bright seed from Colombo (74 bags) was bought in at 2d today. The other day it realised 2½d per lb.

VANILLA.—Dull of sale. For common Mauritius 5s to 7s 6d was paid today, and from 2s 6d to 5s 9d for very low to fair long foxy Ceylon beans. It is estimated that the coming Mauritius crop will amount to 13,000 kilos. The new crop of Mexican beans is now arriving upon the New York market. It is reported that the later arrivals are of rather better quality than some of the earlier shipments.

CINCHONA PLANTERS CLOSING THEIR RANKS.

We announced some time ago that the Dutch Indian Government were about to commission an official of the Java Government plantations to investigate the manufacture of quinine in British India with a view to the establishment of a quinine-factory in Java. Mr. Van Leersum, the official in question, is probably by this time on his way to British India, where he is certain to receive from the heads of the British Government plantations every possible assistance in the discharge of his mission. The British Indian Government has always shown itself exceedingly liberal in allowing other nations to participate in the benefits of its industrial experiments; and, on the other hand, the Dutch Indian Government has on more than one occasion rendered valuable assistance to the British authorities in supplying them with cinchona seed and plants. The process of quinine manufacture at the Naduvatam factory in the Nilgiri district has been fully described in our issues of June 9th, 1888, and December 20th, 1890, and it will, therefore, be enough to say that it consists in beating up a mixture of powdered bark, water (rendered alkaline with caustic soda), and paraffin and fusel oils in a revolving cylinder for three hours, then dissolving out the alkaloids by means of water acidulated with sulphuric acid, filtering the liquid through charcoal, and crystallising on the sulphate of quinine. The cost of the first batch of quinine made at Naduvatam, calculated at the European market value of the bark, was 1s 6d per oz., but since then it has probably lessened. Plant, sulphuric acid, and oil are naturally much dearer than in Europe; labour, on the other hand, costs less than ¼ of a penny per oz. of sulphate of quinine in India, and may, perhaps, restore the equilibrium of the balance of competition. The Naduvatam factory only produces the insignificant total of about 65,000 oz. of quinine per annum, and the object of the Government is simply to provide the native population with a cheap febrifuge at about cost price. The Naduvatam quinine is retailed

16 rупces per lb., or, say, 1s 5½d per oz. The object of the Dutch Indian Government, however, is not to supply a cheap medicine to the Malays of their colonies, but to enable the Java planters to have their bark manufactured on the spot, and thus not only to save nearly the whole of the freight, warehouse, and sale expenses now paid on the bark shipped to Amsterdam, but also to obtain a firm hold upon the quinine markets of the world.

If the Java planters possess sufficient power of combination, and are lucky enough to find an honest, strong, and astute business-man to hold the reins, there seems no reason why, within two or three years, they should not become the dominant force in

the quinine market. Nearly all the Java plantations are situated within a comparatively small area on the west of the island, in the centre of which it is proposed to erect the factory, which will be under Government control, and receive from each planter the bark he grows, returning to him its contents in quinine salts and by-products, and charging, perhaps, a fraction above the actual cost of manufacturing.

That there exists among the cinchona-planting interest a widespread dissatisfaction at the manner in which the control of the quinine market has been allowed to slip from the hands of the growers and their representatives into those of a few quick-witted German quinine manufacturers is abundantly evident. That this feeling of impotence at their helplessness is not confined to East Indian or South American planters is shown by a report which recently reached us from the West Coast of Africa. The proprietors of the plantations on the Portuguese island of Sao Thomé who now send all their bark to London, *via* Lisbon, are casting about, so we hear, for a process which will enable them to send over their produce in the form of a liquor, from which the alkaloids can be regained in Europe. They calculate that such a process would save them about 20s per cwt. on each barrel of liquor. As the bark now shipped from Sao Thomé realises only about 30s per cwt. in sale, the saving would be considerable. It should be stated, however, that the experiment has been tried upon more than one occasion by South American planters, and has proved unsuccessful. The first shipment of concentrated liquor from Bolivia to London was made about thirty years ago. The consignment remained for years in the docks here without finding a purchaser, and subsequent attempts to send over a partly-manufactured article in the form of a resin were equally fruitless. But the failure of these attempts by no means proves that efforts in a similar direction could not succeed now. The inducement is greater, inasmuch as the freight now represents a much larger proportion of the value of the bark than it did twenty years ago; manufacturing processes have been simplified, and the keenest possible competition now prevails among a number of manufacturers in four or five different countries, whereas a generation ago two or three British and French houses, by simply discountenancing an innovation which they did not like, could effectually bar its success. The erection of plants in Peru for the manufacture of cocaine in a crude form has proved sufficiently successful to alter the conditions of the trade in one important drug, and the anxiety of even the most insignificant and backward foreign Governments to promote the establishment of industrial works in their territories may similarly affect the trade in other drugs in future.

But, apart from the establishment of a quinine-factory, there are indications that the Java planters are determined to endeavour to assert the power which effective combination would place in their hands. With the season which commenced on July 1st, Java is taking precedence over Ceylon as a cinchona-producing country. The figures of the actual exports from Java and Ceylon, both reduced to English lb., and both taken for the year on June 30th—the closing date of the Java season—show that in the season just brought to a close Ceylon still gained a Pyrrhic victory in the matter of weight, the figures footing up as follows:—

	1890-91	1889-90	1888-89
	English Lb.	English Lb.	English Lb.
Ceylon	6,900,000	8,600,000	11,890,000
Java	6,000,000	5,225,000	4,857,000

But as the Java bark contains considerably more quinine than that from Ceylon, Java has actually been a greater quinine-producer than Ceylon for at least twelve months.

The principal planters' association of Java has just published a most valuable return of the prospective production of quinine bark in the island for the next two seasons. That return will be found in another column. At the meeting of the association at which it was made public a resolution was also adopted de-

declaring the direct sale of bark by one or two plantations to certain European quinine-makers to be opposed to the interests of the community. What the Java planters aim at, and what they may possibly accomplish with a good man at their head, and effective Government assistance, is shown in a recent declaration of one of their number. "Even if we do not get our factory here," said that authority, "we shall knock the European quinine speculators on the head. In that case we shall form a syndicate, which will regulate the whole of the bark exports from this island. Bark will only be sold to the European quinine manufacturers on condition that they shall turn over all the quinine sulphate prepared from it to a European syndicate, which will take care of the sale of quinine. The by-products the quinine manufacturers may sell without interference. The quinine syndicate will have an agent in every country of the world. That agent will in turn control the provincial agents, who, where the law of the country allows it will sell quinine and quinine preparations of every description directly to the public, and, where that is not permitted, will use retailers as middlemen. The Brunswick factory, the arch enemy, will be altogether excluded from dealing with the syndicate, and the other works are to be expressly prohibited from selling any surplus bark to this concern. The profits will be divided among the planters in ratio of the quinine value of their bark.

The scheme seems a somewhat fantastic one, and if it is attempted to put it into execution it is sure to meet with a determined opposition from many quarters. But as the Java planters now control the bulk of the rich manufacturing barks, and some of their Indian and South American colleagues will no doubt be anxious to co-operate in the scheme if fair terms are offered to them, it would be rash to prophesy its entire impracticality.—*Chemist and Druggist.*

THE PREPARATION OF VEGETABLE TALLOW IN CHINA.

In a recently-issued report by Mr. Consul Hesse on the trade of Winchow, he thus refers to vegetable tallow from *Stillingia sebifera*, which he says occasionally appears as an import, but more frequently as an export. The tree is largely cultivated near Wencho, and still more widely within the Ch'u-chou Prefecture to the west. It is not, perhaps, generally known that the fruit of this tree produces oil as well as tallow. The berries, which resemble coffee-beans in appearance and size, are first steamed and then pounded in an ordinary rice-trough. By pounding, the soft mealy mesocarp is partially separated from the kernels, the whole is then placed in a bamboo-sieve, the meshes of which are just large enough to allow the mealy matter to be scrubbed through, and small enough to keep back the kernels, which are hard, black, and about the size of Peas. From the mealy matter the tallow is expressed in primitive wooden presses. The oil is derived from the kernels in the following manner:—They are dried and passed between two millstones, held at such a distance apart, by means of a bamboo pivot, as to crush the hard shells of the kernels without injuring the white interior. The whole is then passed through a winnow, which separates the broken shells from the solid matter; the latter is then placed in a deep iron pan, and roasted till it begins to assume a brownish colour, the process being accompanied by continuous stirring to prevent burning. The crushed shells make an excellent fuel for this purpose. It is next ground by a huge stone roller in a circular stone well steamed, made into circular cakes with Bamboo and straw casings, and passed through the wooden press. A good lighting oil, called "Ch'ing yu," of a brownish-yellow colour, is thus obtained. The tallow is called "pi yu;" that is, skin or external oil.—*Gardeners' Chronicle.*

JAVA AND THE QUININE MARKET.—At a meeting of the Soekabemi (Java) Agricultural Association, on July 14th, the directors communicated the result of careful investigations on the subject of the prob-

able supply of quinine from Java bark during the years 1892 and 1893. The information is based upon the replies to circular letters sent by the association to all the Java cinchona planters. In only a very few instances were replies withheld, and in nearly all these the association, though its relations with neighbouring planters or financial houses, succeeded in obtaining the desired information: If all the plantations in Java were uprooted, the resulting produce would represent 710,000 kilos (—about 25,000,000 oz.) quinine sulphate. That, of course, would be the end of the Java cinchona industry. The equivalent of quinine sulphate in the estimated bark exports from Java is as follows:—1891, 137,000 kilos (1,830,000 oz.); 1892, 151,188 kilos. (5,340,000 oz.); 1893, 155,175 kilos (5,490,000 oz.) The increase, therefore will be proportionately smaller than during the past few years, when the bark sold at the Amsterdam auctions represented:—Quinine sulphate, 1887, 33,740 kilos.; 1888, 47,431 kilos.; 1889, 77,090 kilos.; 1890, 121,420 kilos. The great increase in the sales of bark at Amsterdam in 1890 is due partly to the fact that the direct shipments of Java bark to London were smaller in that year than in former years, and partly to the uprooting of several plantations. At present seven plantations are about to be uprooted.—*Chemist and Druggist.*

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for October :—

THE CONGRESS ON SEWAGE-UTILIZATION.

UNDER the presidency of H. R. H. the Prince of Wales, the Seventh Congress of Hygiene and Demography held its meetings last week in London. The attendance

is reported as being larger than on any previous occasion, and the foreign delegates considerably exceeded 2,000. The subjects of Hygiene and the prevention of diseases in man and animals were dealt with under 10 different sections, and a new department was inaugurated for the consideration of diseases communicable from the lower animals to man and *vice versa*. In the several departments many instructive papers were read, interesting not only to medical men and veterinarians, but to all communities at large, while most of the papers called forth valuable discussion. The varied nature of the business of the Congress testified to the rapid progress that is being made in so many departments of knowledge, and to the practical research of numerous trained and earnest workers who are elucidating the problems of life, and are applying the information acquired to the benefit of humanity.

From the incomplete reports of the work of the Congress which have reached us, we are not in a position to fully review those sections which must have a practical interest to agriculturists.

Dr. Carpenter contributed two papers on sewage, and insisted that it was the duty of local authorities to utilize the sewage of towns, even although the process might not prove a commercial success. General testimony was borne

to the value of sewage-grown forage, especially for dairy cows, and of sewage-raised vegetables and fruit as human food; and it was shown that as long as sewage was properly supplied, it communicates no injurious qualities to growing plants, nor does it prove a nuisance to those residing in the neighbourhood: indeed, evidence was adduced of the improved health of Croydon and other places since sewage had been applied to the fertilising of adjacent lands.

We have before this referred to the desirability of utilizing the sewage of towns in Ceylon for agricultural purposes. It will, we admit, take time to overcome the objection of the generality of people to fresh sewage matter being brought in contact with vegetation intended for food, however much distinguished men like Dr. Carpenter may aver that it communicates no injurious properties to plants if intelligently supplied. We have witnessed sewage farming about Edinburgh, London, Paris and in Yorkshire, and experienced very little discomfort in walking through the irrigated fields. It will of course be said that the heat of the East will, by more quickly decomposing, give more foulness to the sewage matter. But there is another method of utilizing sewage besides sewage-irrigation, and that is the conversion of it into *poudrette*. According to Dr. Carpenter, it is the duty of Municipal bodies to utilize sewage matter even if the process results in financial loss. It is more likely that in many cases there will be profit rather than a loss resulting from this latter process, for while the cost of manure-making will not be much more than the cost of removing the sewage and other refuse matter to distant places, there ought to be a good sale of the manure and a fair income resulting. There is at least one Municipal town in Ceylon where sewage, blood and other refuse substances are made up into a compost and left for the time necessary to transform it into a valuable and by no means very disagreeable manure; and it is desirable that Colombo should follow the lead of the town above referred to, and appoint one of the minor officers

of the Sanitary division of the Municipality to superintend the work of poudrette manufacture, after having seen the process in working where it is carried on:

There is more than one spot where sewage matter, and blood and other refuse from the slaughter-houses, together with coir dust could be manipulated without proving a nuisance to the public.

We hope to find this suggestion carried out, as there is little that could be said in the way of objection; for while we would be glad to see illustrations of agricultural economy such as this, there is the high authority of the speaker at the Congress of Hygiene and Demography, that the utilization of sewage for agricultural purposes is by no means antagonistic to the fundamental principles of sanitation, that should carry great weight with our city fathers. In our last issue we quoted a passage to prove that a large income was being realized by the Municipal towns in the Punjab by the sale of sewage and other refuse matter. We reproduce the following sentence:—

"The sooner this prejudice (against the utilization of sewage in farming) disappears, the better for both the Municipal coffers and the agriculturist, as a common gain must fall to both."

OCCASIONAL NOTES.

The Sub-Committee appointed by the Legislative Council to report on the Ordinance relating to Cattle Disease, have recommended that the duties and powers vested and imposed on the Inspectors should be exercised and performed by the Government Agent, it being impracticable to procure in the island Inspectors having sufficient veterinary knowledge to carry out such duties to the satisfaction of the public. We suppose that this suggestion will be carried out pending such arrangements as will secure the Inspectors with the necessary veterinary knowledge. We would suggest that a qualified person, and one who has had some experience of the working of measures relating to cattle disease, should be appointed to draw out a list of instructions, as a guide to those who are to assume the duties of veterinary inspectors, till these latter are available.

Of late there have been reports of "foot-and-mouth disease" from more than one district. There are two forms of this troublesome disorder:—(1) Sporadic apthia, and (2) Epizootic apthia. The former which affects few (and especially young) animals is controllable to a great extent by aperient medicines and astringent washes, but the latter which affects large numbers, is very hard to deal with. It is commonly known in Scotland by the name "Murrain" which, however, has a totally different application with us. Affected animals should be isolated and care should be taken that they are kept in a clean dry place. A dose of $\frac{1}{2}$ to $\frac{3}{4}$ of a pint of linseed oil (according to the size and age of the animal) with an ounce of powdered ginger should be given to act on the bowels, the mouth should be washed with a solution of alum in water—one ounce to a quart—and the feet with a stronger solution, and the hooves kept clean

and dressed with blue vitriol (copper sulphate) or zinc sulphate or salicylic acid or zinc chloride or carbolic acid and glyceric ($\frac{1}{2}$ oz. to 6 oz. of water) or strong mixtures of Condy's fluid or Jeye's disinfectant and water. It is a good thing to relieve the vesicles and hasten their healing, and to cut and remove all detached pieces of the hoof. Rock salt should be supplied for the animals to lick.

Eleusine Indica (crow-foot or crab-grass) the Sinhalese Belatana, or as it is sometimes called the wild kurrakkan, is a variety of the Indian ragi (*Eleusine Corocana*) the Sinhalese kurrakkan. It is figured and described in the New South Wales Agricultural Journal for February last. The Botanist to the Agricultural Department thus refers to it:—"A coarse, erect, tufted perennial grass... recognised by its dark green colour, strong stalks, and digitate panicles, the spikelets of which are flat, and overlap each other. It grows nearly all the year round, but during the summer months yields a great amount of rich succulent herbage, which is much relished by cattle. If cut when it first shows its flower stems, it makes excellent hay. Mr. G. D. Hilder of Kempsey, forwarded a specimen of this grass to me for identification quite recently, with a note to the effect that it was a 'very good grass for cattle, and that they ate it greedily.' It is a grass that is worth disseminating on moist lands in the coastal districts; and as it produces a great amount of seed if left undisturbed for a time, there would be very little trouble in collecting my quantity. Besides its value as a forage grass, it is useful for binding the banks of rivers, dams, and loose earth. Its tough fibrous roots penetrate deeply into the soil, and in time form a perfect mat, so that flood-waters would have little effect upon the land where it was firmly established. It will even undergo partial submersion for a few days without the slightest injury." This hardy grass grows abundantly in the warmer parts of Ceylon, and cattle are very fond of it. Native medical men recommend it for external application in cases of sprains.

Two varieties of Cumbu (*Penicillaria spicata*) are grown in India: the ordinary variety is that grown as an unirrigated crop, while that known as *Mummani Cumbu* is an irrigated crop. The plants of this latter variety are shorter than those of the other, and mature sooner, the ears appearing as a rule at fourth node. Cumbu is considered an unexhausting and ameliorating crop. It is largely grown and relished as a food by the natives of South India. It is a common proverb among them that "cumbu is equal to paddy as food." The crop is not usually manured, and is generally chosen for exhausted lands. It is either grown alone and successively on the same land year after year, or with other crops such as green gram. The ears are reaped two or three times before the straw is cut. The chaff is used as a bedding for forming straw stacks, and subsequently added to the manure heaps. The straw, which is inferior to paddy straw, is not of much value as fodder. Cumbu is grown to some extent in the island, and principally in the North-Western Province. A small extent of the new land attached to the

School of Agriculture is about to be laid under cuabu.

A small quantity of the seed of *Lathyrus Sylvestris* for experimental cultivation at the School of Agriculture, has been indented for.

Of Cholom (*Sorghum Vulgare*) there are two varieties grown in South India, Songucholom and Arisicholom. In the former the grain has many husks, in the latter the grain is visible protruding over the husk. The former variety which is raised for fodder may or may not produce ears. It principally follows cotton. Cholom straw is wholly consumed without any portion being rejected. The crop is reaped in 4 months close to the ground, the roots remaining or not, as the soil is hard or soft, in the ground. About three cartload of 40 bundles each is said to be a fair outturn of fodder. Cholom is grown as a grain crop without rotation where sand predominates, and the grain of this *Arisicholom* is eaten by the poorer classes. The straw and chaff are given to cattle, but consumption of the grain by them is said to be attended with distention of the stomach. The albuminoid ratio of cholom straw is the lowest of all Indian fodders, but, says Dr. VanGeysel, Chemical Examiner, Madras, "without further information as to the digestibility of the straw, it is not possible in reference to the analysis of cholom to explain the high repute in which the fodder is held, although in respect of the total amount of nutriment contained in it, it is superior to all the other Indian fodder straws."

The *Agricultural Gazette* of New South Wales declares that the value of Sorghum (*Sorghum Saccharatum*) for the food it furnishes to man in the form of flour from grain, of sugar, and of mollasses, and to animals in the form of green fodder, ensilage or grain, has not been fully recognised. Its value as a source of sugar has been conclusively shown in the United States by exhaustive investigations, and the financial results of a number of sorghum sugar factories, to be a highly commercial one. The plant also furnishes, in addition to sugar, a large quantity of syrup of the best quality, seed, and other by-products of commercial value. It is, in fact, a plant which has been found to pay the farmer to cultivate. Sorghum is said to succeed wherever maize will grow, and provided it gets a good stand in the earlier part of the season, will even flourish during a drought far too severe for maize. Three to four crops can be obtained in a year from sorghum, which, whether in the form of green food or chopped with straw, is very much relished by stock. The clean seed, as food to man or animals, is fully equal in value to either maize or oats, and but little inferior to wheat. The average yield of seed may be put down at 30 bushels per acre.

SOME USEFUL EXOTIC PLANTS.

I. *The Bassia Latifolia.*

Among the plants which Mr. J. P. William of Henaratgoda has grown for sale, there are several very useful ones, which would readily

find a home in the Island and prove to be highly remunerative. Among these is the Mahawah tree (*Bassia latifolia*.) The genus *Bassia* is represented in Ceylon by a widely-growing and useful timber tree, the *B. longifolia*. Apart from the uses to which the timber of this tree is put, we find the villagers making its fruits and flowers articles of food. The sweet syrup obtained by boiling the flower calyces is used by the poorer classes in the interior villages for making certain sweets. It is believed that the hard cement which is met with in ancient structures of Ceylon was formed with the syrup of *Mi*, and the large forests of *Mi* trees which existed at the period would have supplied this article to a large extent. The *Bassia latifolia* is, however, not indigenous to the island. This plant would appear to be of very great economic value, and it is being at the present day introduced into many countries. It grows well in India, and the extension of its cultivation is contemplated by the Indian Forest Department. The tree is a very handsome growth, attaining a height of from forty to sixty feet, and it thrives in dry stony soil, and in fact grows well in all soils at the sea-level and up to very high elevations. The flowers are used in distilling a spirit very much resembling arrack; and a single tree bears from 200 to 400 lbs. of flowers in a season. On account of the large percentage of saccharine matter found in them, they are used as an article of food both for man and beast, apart from their value as producers of spirit. The seed, like our country *Bassia*, the *Mi* tree of the Sinhalese, contain a large percentage of oil, and this oil is used for lighting purposes and in the manufacture of candles and soap. The oil cake is also valued as a food for cattle and a good fertilizer. The timber of this tree is hard and strong, and is used for carriage wheels, railway sleepers, &c., while a gum is obtainable from the bark.

The cultivation of the plant presents no difficulties, and it recommends itself for growth in any plantation. It would be well if our Forest Department also decided on planting the tree in the different districts of the Island. Not only will it be a means of adding to the food supplies of the villagers, but also as a means of adding to the revenue. Besides, the extension of the railway system in the Island necessitates the importation of timber, and this fact should weigh with the Forest Department authorities in deciding, on the cultivation of such useful exotic timber trees as the Mahawah tree.

W. A. D. S.

THE CULTIVATION OF THE COCONUT PALM.

II.

Having selected the seed nuts, they should be planted in rows in a horizontal position, sufficiently deep to properly cover the germinating side, in beds, which should be divided by narrow paths for convenience in watering. The nuts are generally put down in the nurseries as close together as possible—say with a four finger breadth space between two. The beds may advantageously be repared between two rows of palms, or in the

centre between four trees, or, if in new land, under large trees in well-worked-up soil, which has afterwards been mixed up with decaying leaves and compacted. If the beds are laid down in the open, it is advisable to lightly cover over the planted nuts with a quantity of old straw which will protect the nuts from the sun, and eventually decay and mingle with the soil. The beds when prepared after the first two methods, should be watered three times a week, but if straw be used to cover them, twice a week will be sufficient. If a copious shower of rain fall, 12 or 14 days may be allowed to elapse before again watering. The nuts, if damaged in no way, will begin to sprout from 3 to 4 months after planting, and in six months' time will be ready for transplanting. It generally happens that some plants will be more forward than others, owing to difference in the thickness of shell. Those trees which have nuts with very thick shells are considered very valuable, and are called "fighting coconuts," fetching from 25 to 50 cents each, especially about the 12th of April, the date of the Hindu New Year, when "coconut fighting" is a common pastime.

In former times the rows of plants, when transplanted, were put 24 feet apart, but this plan was found to be a mistake, as the trees did not sufficiently shade the ground. Now all new plantations have the rows 22 feet apart, and the new method not only keeps the ground cooler but at the same time economises space, each acre thus containing about 90 plants. If, from necessity, plants have to be selected from native nurseries, tall spindly ones should be rejected. A good plant should have dark green leaves, a stem inclined to be thick, and 2 or 3 feet in height. Plants with yellow leaves should be avoided—as this is an infallible sign of weakness.

The holes for receiving the plants should be about 3 feet square and $1\frac{1}{2}$ to 2 feet deep. Care should be taken to remove any stones and roots that may be in or near the hole, while just before planting it is advisable to throw in half a bucket of water to keep the soil moist till the regular watering commences. In transplanting the palms the young roots should not as far as possible be injured. A stout-pointed stake may be used as a lever for raising the nuts in the nurseries.

After placing the palms in the holes prepared for them, a quantity of decayed leaves, wood, &c., may be put round each plant before filling in with earth. Stump the loose earth well, taking care that the plant remains perfectly straight. Then make a circular bed all round the palm to retain any water put in, and conclude by pouring over a full bucket of water.

R. ATHERTON.

(To be continued.)

THE DAIRY.

Dairy work in Ceylon should receive more attention, and a proper supply of good milk and butter ought to be brought within the reach of the inhabitants of our cities and towns. The residents of Colombo are aware how difficult it is to procure pure cow milk, what is sold as such being very often adulterated with buffalo milk

and water in various proportions. The adulteration of milk with water, if the water is good is only a minor evil, the loss being only in pocket, but it is a far more serious matter if the milk has been obtained from a diseased cow, and what guarantee have we that the milk offered for sale in our streets is the produce of healthy animals? The milk is also affected by the nature of the water that the cow drinks, or that added to the milk. Microscopic investigations have revealed the fact that if a cow is allowed to drink water containing animalcules, these minute forms of organised life may be found in its milk.

The ill-effects of drinking diseased milk may not be always apparent especially in the case of adults, but there are instances known where disease and death have been directly traced to the ill-effects of drinking unwholesome milk in the case of children who are the largest consumers of milk. The question suggests itself—what ought to be done to ensure a good and wholesome supply of milk? The mere inspection of the milk would be useless, the only effective and most convenient method being the inspection of dairy cattle and dairies by qualified persons, and prohibiting the sale of milk except by licensed dairymen.

There is a great demand for good milk and butter in Colombo, and this has been to some extent met by the establishment of a dairy on a small scale in connection with the Agricultural School. A year and a half ago we started with only one cow, the whole of whose milk we then found it difficult to sell, in face of the opposition offered by milkmen and bungalow servants, but our hopes have been realised beyond our most sanguine expectations by our possessing today a dairy of 15 cows with an ever-increasing demand for our milk, which we are unable to meet without the small assistance we hope to receive from Government.

In establishing dairies in a country like Ceylon, an important matter is the opportunities they give for the systematic study of the feeding and management of milch cattle, the different breeds, the qualities and quantities of the milk yielded by them, and of the means of improving these breeds, also the necessity for the introduction of improved dairy appliances, &c.

The marvellous dairy results which have been obtained in Europe and America are mainly due to the most careful selection and breeding of good milk-giving strains.

DAIRYMAN.

LATHYRUS SYLVESTRIS.

Lathyrus Sylvestris is the name of a leguminous fodder plant which, from all accounts must be considered nothing less than a boon to the agriculturist, and especially to cattle farmers. Its experimental cultivation is about to be undertaken in India, where, if the experiment prove a success, the plant will no doubt be introduced into, and extensively cultivated in, Ceylon. *Lathyrus Sylvestris* reported to grow luxuriantly year after year on the most barren arid land, and to be excellent fodder for cattle. The plant is a native of Germany, and its merits were first brought to light by Professor Wagner, who improved the wild variety by cultivation for 15 years.

A writer in the *North British Agriculturist* speaks of it in enthusiastic terms as "the plant which in course of years will cover throughout the world the vast areas of arid, uncultivated, and at present mostly uncultivable land, supplying abundance of the most nutritious, sweet fodder to countless millions of horses, cattle and sheep; the plant which will promote the permanent prosperity and progress of stock-farming and agriculture to a certain degree unknown before; the plant which in due course will form the greatest source of national wealth in every land."

According to a report made on *Lathyrus Sylvestris* by Mr. Charles Hope, the plant is said to resemble the everlasting pea in habits of growth and in general appearance, and the blossoms are of a reddish purple colour. The seed takes rather a long time to germinate, and the plant takes three years to come to maturity, multiplying freely by means of creeping underground stems. It is said to yield remunerative crops for fifteen years, when its natural vigour declines, and it is necessary to plough up and re-sow. The expense of seed and labour per annum is consequently very small. The quality as shown by analysis is twice as good as any other fodder plant at present in cultivation, weight for weight, in the natural green state. The small quantity of water naturally present in the green plant is a very conspicuous item, helping not a little towards the foregoing statement. The rest of the extract does not show very much chlorophyll, and is more like oil than wax. The great advantage is in the very high percentage of albuminoids which is the more fortunate, seeing that the natural order is not benefited to a remunerative extent by direct applications of nitrogenous manures. The percentage of indigestible fibre is naturally lower in the young plant, and the tissues of the plant should not be allowed to grow old. The ash is very high, and will no doubt afford plenty of bone-forming material for young animals, and be very suitable for cows yielding a fluid which is intended to nourish the young. The albuminoid ratio is wonderfully high, being as 1 : 4.5, and most nearly resembles the concentration of bean, which shows a ratio of 1 : 4.2, than any other simple food. Hence it must be considered a very concentrated food, twice as concentrated as any green fodder in cultivation. It will probably be found economical to dilute the food, feeding along with it some straw or roots, until the desired ratio be obtained. The most approved ratio for cattle is 17 at the commencement of feeding for fattening, and this is gradually raised to 1:55 to finish. The albuminoid ratio of oats being 1 : 6.5, and the ratio for a horse according to Wolff being 1 : 9, it follows that *Lathyrus Sylvestris* is more than sufficient to maintain a horse at work. It is customary to purchase concentrated foods, and by mixing to make the ratio for horses and cattle more nitrogenous, but here is a plant in which the reverse process appears to be the proper course to pursue, the hay of which reminds one of the composition of cotton-cake. Cattle are reported to eat the fodder freely and at once, so that there is no question of its palatability. The German reports put the produce at 17 tons per acre. If any manures

are to be added with a view to benefiting the crop they should be phosphates and potash, as nitrogenous manures are not likely to yield a profitable return. It is stated, however, that the plant will never require any manure of any kind. As soon as the crop attains a sufficient length for the scythe, it should be cut; the same plot may be cut from 3 to 5 times in a season. It should not be allowed to bloom, and should not be pastured. The plant is being tried at various places, and is surely worth a trial. Especially in this Island where there is almost a total absence of cultivation of fodder crops for cattle, will the introduction of *Lathyrus Sylvestris* prove of incalculable benefit.

THE GRAPE VINE.

(*Vitis Vinifera*.)

7. *Planting out, &c.*—After the soil has been broken up and exposed to the mellowing action of the air for at least a month, the clods should be pulverized and the land levelled before it is ready for planting. If it is flat and free from rocks the iron plough may be used for ploughing it, and the harrow or the native plough for breaking down the clods. If, however, the land is rocky and uneven, the mamoty will have to be used for both purposes.

When the cuttings strike and have grown to a sufficient height, say two feet, they are fit for transplanting. The spots where they are to be planted may be previously marked out by means of pegs, &c. The vines should not be planted too close to each other. No false economy with a view to saving land should be allowed to spoil a vineyard, which is to last for more than a lifetime. The Rev. Father Assauw, of Wahakotte, in reply to enquiry made on this head, has kindly favoured me with the following piece of information:—"The vines I have are 12 feet apart; and those planted last year 8 or 9 feet apart seem to thrive well."

An extract from the Annual Report for 1889 of the Agricultural Department of Queensland is also well worth quoting in this connection. Speaking of Mr. Bassett's vineyard it says:—"Mr. Bassett states that, like many others when first entering upon this industry, he was possessed of very little knowledge of grape vines, or the proper method of laying out a vineyard; consequently after planting the first portion, he found that he had placed the vines too close together, and the rows also too near to each other, viz., 5 feet between and 4 feet in the rows. In the second portion of the vineyard planted he improved his system of planting by placing the vines wider apart, viz., 6 feet in and 5 feet between the rows. More experience was gained by his second planting, the result being that in the last portion planted he adopted what he considers to be the proper space in the Roma district, viz., 10 feet between and 6 feet in the rows."

In a country like Ceylon where plants grow so vigorously and luxuriantly, the distance, I daresay, ought not to be any less.

Manure may be used rather sparingly at first. No raw or hot dung should be used at all. Half-rotten cowdung of the appearance of black mould should be mixed up with the soil

to a depth of $1\frac{1}{2}$ feet, in holes 3 feet wide, before the young plants are set. [Subsequent manuring will be considered later on.]

The plants should be removed carefully from the nursery bed without injuring the roots, if possible with the clod of earth holding on; and as soon as each plant is taken up, it should be planted in one of the prepared holes, watered and shaded. The shoot should be supported by loosely tying it to a stick driven into the ground. Watering should be continued regularly morning and evening until the young vine is well established in the new place. It is however best to avail ourselves of the wet season for the purpose of transplanting.

E. T. MOORE.

Haputale, 24th September, 1891.

(To be continued.)

CRUDE THEORIES REGARDING THE ORIGIN OF CERTAIN PLANTS.

Like most economic plants the jak tree was originally found growing wild, and its value as a food was known to none. It was in fact considered to be a poisonous growth, till the god Sakra made its value known by a strange method. This divine benefactor is related to have descended to earth having assumed the form of an old man, and carrying a large-sized jak, to have presented himself before a village housewife, entreating her to boil for him the fruit he carried. With some persuasion the woman was induced to do the service asked for. After delivering his burden the old man went away on some pretended business, giving the woman strict injunctions not to taste of the fruit. The strange plan of the god succeeded well, for with the proverbial curiosity of a woman, the housewife, like her mother Eve, was most inquisitive to know what the fruit tasted like, for the aroma of the boiling jak rather pleased her. Having gingerly tasted a portion of a seed, she was quite fascinated by its agreeable flavour, and eventually partook of the greater portion of the boiled fruit before the old man arrived. The transformed god on his return seeing what had occurred, accused the woman, calling her *Hera Lecya* (woman thief) and disappeared. Since that time the jak was known by the name of *Heralecya*, while the fruit (like the roast-pig of Lamb) became a favourite food with the people.

The coffee berry too as it originally grew in its wild state was looked upon as a poisonous fruit. It is related that a certain woman having quarrelled with her husband made up her mind in a fit of anger to put an end to her miserable existence by taking some poison in his absence. Rushing into the neighbouring jungle, she found a tree laden with red berries, and gathering some of the fruit, peeled off the outer husk, and attempted to eat the seeds; but these were so unpalatable that she decided on roasting them first. The roasted coffee, however, proved more bitter and distasteful than the raw beans, and being unable to swallow them, she conceived the idea of reducing them to a powder, and after mixing this with water, drinking it down. By a strange chance there was a pot of hot water near at

hand, and this water she poured over the coffee powder, drank off the infusion and prepared herself for death. To her astonishment, however, the enraged wife found that the coffee, so far from acting as a poison, seemed to enervate her, and at the same time to calm her rage, till she felt ashamed of her cowardly attempt to take her life. On the return of her husband she went to him in contrition and confessed all, and he, after mildly rebuking her for her weakness, decided to himself to try the infusion of the berry, which he pronounced excellent. Henceforward coffee became a favourite beverage, and the berry was called *Kopé* (anger), since it was the anger of the woman that was the means of discovering its virtues.

W. A. D. S.

GENERAL ITEMS.

M. Leon Mundereau, a French *savant*, claims to have made the discovery that in cases of "localised" tuberculosis (such as is confined to the lungs, pleura, or liver), the aqueous humour in the eyes contains the characteristic tubercle bacillus in sufficient numbers to be readily identified, in different stages of the disease. In the case of living animals the aqueous humour is obtained by puncturing the cornea.

Ringworm, which commonly occurs among cattle, and especially calves, is due to a vegetable parasite—*Trichophyton tonsurans*. Affected animals should be isolated and taken in hand as soon as they show signs of the disease. The spots should be washed with plenty of soft soap in warm water, but care must be taken not to spread the fungus—scabs and scabs being removed by soaking with carbolic acid. Among the remedies commonly employed are solutions of corrosive sublimate and biniodide of mercury, both active poisons and requiring careful use, carbolic acid and preparations of iodine and iodoform. A safe and effectual dressing which should be well rubbed in, is prepared by mixing one part each of tincture of iodine and ordinary paraffin with ten parts of vaseline. This should be applied daily for 3 or 4 days, and in cases of old standing the washing with soft soap and the dressing should be repeated every second day for a week. To destroy all traces of the parasite, all manure and filth about the cattle sheds should be removed, and the floors and woodwork wetted with a one-thousandth solution of corrosive sublimate, with which also all harness, linters, clothing and brushes should be washed or boiled.

A report sent into the Queensland Department of Agriculture deals with experiments in jam and jelly making with mangoes. In Ceylon, jams and jellies made of these fruits are common enough, but whether their manufacture for commercial purposes will pay remains to be seen. The abovementioned report refers to an excellent marmalade than can be made of the fruit, and goes on to speak of "the great possibilities" in connection with the mango crop, and declares that if the fruit be put into the market in the shape of jelly and marmalade, it would be certain to come into universal popularity, and that it might be manufactured and sold at a handsome

profit. With its abundant crops of mangoes Ceylon might send almost an unlimited supply of the preserved fruit, but until it be proved that the manufacture will pay—and an attempt has already been made with this object in view—no one is likely to start the industry.

General Fisher, R. E., writing of water required for rice cultivation, says:—"The quantity used in the Godavery and Kistna Deltas, *viz.*, '015 c. ft. per second per acre, or 2 c. yards per hour, has been found, from many years' experience, to be ample, and immense volumes go to waste for which drainage works have to be provided. So far, then, as South India is concerned, in such localities everything appears to have been done which is at all necessary, so far as relates to the quantity of water required for such irrigation. A correspondent, however, states that in Italy the quantity given varies from '036 to '14 c. ft. per second per acre. The former is more than double the quantity usually allowed in India, about 4'05 c. yards per hour per acre, and the latter in upwards of 18'7 c. yards per hour per acre; the question then is how would it be practicable to secure such supplies of water in the dry months in India? To store water for 1,000 acres, say for 120 days' supply at the rate of 7'12 c. yards per hour per acre, we want nearly 50 million c. yards to be stored in order to provide for evaporation, leakage, &c., and for such extent of land as we have in the deltas the quantity required would be 25,000 million c. yards of water. It is quite plain, then, that the Government could never go to such an expense. If the Italians do obtain such quantities it must be from rivers which are supplied in the hot months by natural

reservoirs from the snows melting in the hills or lakes. So far as my knowledge and experience go, I should say they use too much instead of too little water in India, and this is confirmed by the practice of the natives in using well-water when it is said a field requires to be irrigated once in 3 or 4 days; and I have always found that it was quite easy in tank irrigation to cut off the supply largely during the nights. The waste which now goes by no one attending at all to the sluices of a tank is enormous; these are allowed to discharge day and night through their apertures, exactly in the same way whether the heads over them are 5 feet or 20 feet. Now the velocity in the one case would be 215'3 inches per second, and 430'6 inches per second in the other theoretically. The loss of water in tanks I believe is not due so much to evaporation as to this huge waste by mere carelessness and negligence. If the rice were cultivated in India as it is in South Carolina, very much less water would be required, and the yield be much greater. There is apparently no difference in the seed as South Carolina had this conveyed there originally from the Mauritius, but the Yankees allow of no such thing as "mamool" to keep them sticking in the mud."

The Cow-tree which is found growing in the rocky arid plains of South America to a height of more than a hundred feet, and first described by Baron Humboldt, yields a rich nutritious milk. The juice is obtained from the stem by making incisions, and is collected by natives in gourds. It is used with cassava and Indian corn bread, and for several months in the year is the principal food of the natives.

[No 5.]

THE QUALITIES AND COST OF THE LEADING FERTILIZERS EMPLOYED IN COFFEE CULTURE

RE exhaustively dealt with in Mr. Pringle's letter which we publish below. Of course the main principles which apply to coffee culture, apply equally to the tea enterprise; and as but few estates in Ceylon can afford to provide cattle manure on a large scale, planters will do well to give full consideration to the arguments, founded on the enhancement of original price by cost of carriage in favour of taking every precaution to secure artificial manures of the very best quality: those in which phosphates and ammonia are most concentrated. It is interesting to learn which are the best of the mineral (fossil) phosphates of Europe or America, but with so fruitful a source of fresh bones next door to us in India, our business is to see that we obtain the best of these. So with castor oil cake; while, if we use fish, we are bound to see that it contains a minimum of the substance with which some grocers are said to mix their sugar. Large dealers in fertilizers to whom appreciable orders are sent, cannot object to bear the cost of analyses of the substances they sell, so that the buyers may have a guarantee of the real value of the articles they purchase, with the prospect in most cases of considerable cost of carriage by rail carts and on coolies' heads; all of which are as heavy for inert as for active matter.

Coffee is of some considerable interest still in Ceylon, and the enterprise may some day revive. Meantime, Ceylon planters will, if guided by their own experience alone, feel surprise if not scepticism, at the effects attributed to manures in "booking up" trees badly affected by leaf disease. What happened here, when the disease became virulent was that manuring merely enabled an affected tree to put on a fresh coat of leaves for the fungus to suck the life blood out of. But there was a second enemy which was fed, especially by cattle manure, and that was the deadly rootlet-devouring white grub.

While much is said in these South of India letters of the ravages of the stem borer (a very minor and rare evil in Ceylon) there is not a word said about the pest which in our case sapped the life of the tree at its root, while the fungus destroyed crop after crop of foliage, in the elaboration of which the unfortunate coffee bush exhausted its energies.

Happily, tea seems exempt from both of these deadly plagues, and as yet no other of much consequence has visited our staple. But as the estates advance in age, more or less exhaustion of the nutritious elements of the soil will be inevitable. The loss must be supplied, mainly with artificial manures; and the information supplied by Mr. Pringle must be of value to the planter, in his efforts at effective but economical manuring

VALUE AND VALUATION OF MANURES: PART II.

By WILLIAM PRINGLE, M. S. C. I.,

AGRICULTURAL CHEMIST TO MESSRS. MATHESON & CO.

*(Under special arrangement for publication in the
"Ceylon Observer" and "Tropical Agriculturist.")*

Bones as mentioned in Part I have Phosphates *i. e.* Tricalcic phosphate varying from 39.40 per cent up to 57.08 per cent and Ammonia from 3.01 per cent up to 5.23, taking the cost of standard quality bones on the coast say R60, then the value of the samples would be as follows:—

	Standard.	Highest.	Lowest.
Phosphates	48 per ct.	57.08 per ct.	39.40 per ct.
Ammonia	4 "	5.23 "	3.01 "
Phosphates at R $\frac{3}{4}$	36	43.81	29.55
Ammonia at R6	24	31.33	18.06

Total value R60 75.19 47.1

The buyer pays R60 for an article that may only be worth R47.61 or it may be worth R75.19; there is a money value of R27.58 between the highest and the lowest.

Supposing that 4 cwt. of standard quality bones are to be used and the poorest quality are supplied it will be necessary to use 4 cwt. 3 quarters and 13 lb. nearly 5 cwt. to make the quantity of phosphates equal; while with Ammonia to make it up to the standard 5 cwt. 1 quarter and 9 lb. would be needed; so that to make No. 3 equal to the standard it would be advisable to add 30 lb. of 6 per cent oil cake to the 4 cwt. 3 quarter and 13 lb. of bones 3rd quality to bring it up to the equivalent of the standard. With the highest quality the whole is reversed. Roughly speaking, suppose the phosphate value to be set against the Ammonia, the proportion required would be highest 3½ cwt. standard 4 cwt. and lowest 5 cwt. that is to get the money equivalent on the

basis mentioned; to get the full manurial value the manures would have to be adjusted with in the case of the lowest, by increasing the quantity used and adding some nitrogenous matter to bring up the ammonia. In the case of the highest the addition of a little more burnt earth or cattle manure would reduce it to the standard, the consumer benefiting in the reduced cost of carriage.

The question of carriage is of as great importance in the case of bones as it is with oil cake; and a very little consideration will show that it is worth while to take a little trouble to secure a first rate article; in England if the bones are not up to the standard guaranteed, the vendor pays the cost of the analysis and makes an allowance to cover cost of carriage.

One large firm of manure manufacturers in their annual circular issued in the spring of this year (1891) make the following allowances:—

15/0d	per unit for ammonia
9/9d	do do soluble phosphate
2/6d	do do bone phosphate

The only stipulations of importance being that the surplus value of one element shall be set against the deficit in the others if any exists; and that they have the right if they are not satisfied with the analysis, to have a second one made and to strike the average of the results.

Steamed bone flour as it decomposes more easily is considered to be worth five per cent more than the raw.

The physical condition is in most cases, and on the generality of soils very important, and is worth paying for, as it means a quicker action when finely divided manures are used. If manuring can only be done on one-third of the estate per year, so that the whole is only manured once in three years, a mixture of steamed bone flour, raw bone meal, with if necessary some fish meal and oil cake to supply the extra ammonia would be a suitable manure, as the materials would not all decompose at once nor at the same rate, but would gradually yield up the food to the plant; the proportions should be adjusted to suit the soil, climate, &c. &c. Where possible I would prefer annual broadcast manuring.

Fish when pure and dry is a very valuable manure, it decomposes more readily than either steamed bones or oil cake, when ground down to meal it is a very powerful stimulant, and must be used with care.

The commercial article is often mixed with large quantities of sand; I have examined some that had 80 per cent in it, but the following analyses show that with care the sand and insoluble matter need not exceed 2 per cent. All over this should be deducted from the gross weight, and if it exceeds 5 per cent an allowance should be made to defray expense of carriage. I also give the analyses of two samples by John Hughes, F. I. C. & Co., which represent the ordinary article of commerce where no limit is placed on the amount of sand. Mr. Hughes found as much as 62 per cent of sand in a sample and he considers No. 1 to be a fair average of fish usually imported to Ceylon, No. 3 fairly represents the best quality delivered in Coorg, and the supply is practically unlimited; it could be greatly improved by squeezing some of the oil out of it.

Hughes' No. 2 sample is worth a little more.

It is usual to consider $\frac{1}{2}$ per cent under or over the whole number a fair allowance for errors in sampling &c. and to pay on each half per cent. It is a fair give and take arrangement between buyer and seller. Thus 10.5 per cent is paid for as 10 and one $\frac{1}{2}$, 10.8 or 10.7 at the same rate, but 10.8 is paid for as 11 and 10.2 as 10.

So far I have dealt with readily procurable native manures, but where carriage is very expensive, it is cheaper to use more concentrated manures which can be diluted with burnt earth or cattle manure or weed compost, or jungle, or soil &c. as may be thought best.

In other cases a heavy crop is on the trees and they are to be backed up; a quick acting manure must be used to enable them to satisfactorily ripen it, and leave the trees fit for the next one. So with leaf disease or anything else that exhausts, backed up by easily assimilable food not only help the trees to recover rapidly, but minimize the risk of loss of crop.

First let us consider a case where carriage costs say R50 per ton and 6 tons ammonia is to be supplied. 100 tons oil cake 6 per cent at R6 per unit = R3,600 Carriage of 6 tons of ammonia ... 5,000

Cost of 6 tons on the estate ... R8,600

Equal to per ton of ammonia ... R1,433
10 per cent oil cake is worth to the planter quite one rupee per ton more than 7 per cent and a fair price for it would be seven rupees per unit ton; 60 tons will give 6 tons ammonia and the cost is

60 tons oil cake 10 per cent at R7 per unit = R4,200
Carriage of 6 tons ammonia ... = 3,000

Cost of 6 tons on the estate ... R7,200

Equal to per ton ... R1,200

A saving of R1,400 by using 10 per cent at R7 per unit ton instead of 6 per cent at R6, equal to R233 per ton of ammonia delivered. Now if 24 per cent sulphate of ammonia costing R10 per unit ton is used only 25 tons are required, one-fourth the weight of 6 per cent oil cake; a consideration of the utmost importance where the manure has to be carried on the heads of coolies.

25 tons 24 per cent ammonia sulphate at R10 = 6,000

Carriage of 6 tons of ammonia ... 1,250

R7,250

Equal to per ton ... R1,208

By using the equivalents of 100 tons 6 per cent oil cake, with 10 per cent, a saving of R1,400 is effected and with sulphate of ammonia 24 per cent R1,350.

Where the carriage is R50 per ton or less, the 10 per cent. "Hindy" has the advantage over the sulphate in cost; it is however so much slower in action that where immediate results are to be produced the ammonia sulphate is decidedly to be preferred. When

the costs are nearly equal the planter must first consider his true requirements, and the suitability of the manure to his working conditions, climate, soil, &c. If it is necessary to assist the trees over a bad attack of leaf disease, which by denuding them of leaf prevents the ripening of crop, quick acting manures are essentials; and though costing more per unit ton are the cheapest in the end, as they will often repair the damage before it is too late; they should be carefully hacked up so that the first good effects are not lost. Ammonia and lime may be looked upon as stimulants, and like spirituous liquids must be used with discretion, a little whisky or wine often aids digestion but it is advisable to have something in the stomach to digest, otherwise the results are not satisfactory. So it is with plants if you give them stimulants, you must give them food to digest: they must have phosphates, potash, sulphur, chlorine, iron, &c. &c. As regards phosphates we have a wide choice; there are bones, raw of varying grades of fineness, steamed bones, and bone ash, mineral phosphates, precipitated phosphate, superphosphate, guano, and fish. Disregarding the native manures we will just consider the phosphates pure and simple; they should be in such a physical condition that they may be easily mixed with burnt earth &c. Bone ash and mineral phosphates should be sufficiently fine to allow of at least 90 per cent passing through a sieve of 80 meshes per linear inch. The amount of phosphates to bone ash according to MacAdam varies from 62 to over 80 per cent; pure or bone ash contains 86.34 per cent and the average of six samples analysed gave 73.5 per cent. It is usually sold on a basis of 70 per cent. It is much more readily taken up by the plants than raw bones, and is an excellent fertilizer where phosphates are required.

Of mineral phosphates high class Spanish, commonly called Estracodurito, has from 75 per cent to 82 per cent phosphates; inferior qualities are often in the market with only 50 per cent or so in them. Canadian and Norwegian apatites and araba phosphate are generally very rich having sometimes as much as 90 per cent tricalcio phosphate. There are a great number of others but these are the most suitable, and I prefer araba as it is as soft and easily decomposed as bone ash, and is generally cheaper.

Precipitated phosphates are in a much more beautiful physical condition than it is possible to produce by mechanical means and they are almost as valuable as super phosphate the average percentage of phosphates is about 60 per cent. A high class superphosphate with 41 to 45 per cent soluble is as a rule worth twice as much per unit as raw bone flour, the physical condition is perfection and the food is at once available for the plant.

Trees bearing a heavy crop suffer from a bad attack of leaf-disease, we wish to assist them, and determine to apply a complete manure; cattle manure at once suggests itself, the weather is favourable and it is applied, the trees slowly feel its effect and recover, but there is a good deal of light coffee and some of the crop has dropped. We try bones, oil-cake, and woodashes; the results are much worse than with the cattle manure, the mixture is too slow in action.

Next superphosphate, ammonia sulphate and kanite are tried, the trees feel the effects at once and throw out a grand flush of leaf, and the leaves fill out in a wonderful manure. If we know the composition of the soil we can proportion the manure to suit it and the plant's requirements and produce the greatest effect at the least cost.

In fact the value of a manure to the tree or plant depends on the proportion in which the constituents are in it; the fertility and suitability of a soil for a given crop depends on the relative proportion that the easily assimilable elements bear to one another and its physical condition; from this it follows that if there is a proportionate deficiency of any element in the soil that is not supplied by the manure, the results will be to say the least disappointing.

The heaviest loss of value occurs when the manure applied has the same deficiency as the soil. A soil is rich

in phosphates and nitrogen and we feel surprised that bones and oil cake produce no result, commensurate, with the expenditure; cattle manure does much better, therefore the natural conclusion is that it is the better manure for coffee, probably the addition of a little kanite would improve the bone and cake mixture, but it is by no means improbable that if it did so, it would also improve the cattle manure, and an analysis of the soil would reveal the fact that the soil was short of magnesia, chlorine, sodium, potash or possibly sulphuric acid, and it is quite possible that the kanite alone would have given as good results.

If to the cattle manure we add what the soil demands to supply its defects we can manure with the certainty, provided the season is favorable of obtaining good crops, and to had seasons fair ones and a full return for the money spent on manures, soil analyses such as these given by John Hughes and myself which show the relative proportion of the elements available for plant food to enable the planter to economise in his manuring by applying the necessary manure, avoiding the application of what is unnecessary, and the disappointment and waste of money attendant thereon.

To make manuring a success and to ascertain the value of a manure to him on his estate a planter must consider the following points:—

1. His soil.
2. His produce.
3. Carriage.
4. Capital.
5. Labour.

Without the last two manuring and manures are impossibilities, and if the supply of these two necessities is limited, the planter must cut his coat according to his cloth; if the supply is insufficient a planter's best efforts are often cramped, and he has to work when he can, not just when he wishes to, and knows he will get the best result.

Work well done at the right season is the cheapest in the end, and the manure best adapted to his soil and produce is the most economical to use.

WILLIAM PRINGLE.

Bangalore, Sept 20th, 1891.

COCONUT AND PALMIRA PALM CULTURE IN THE NORTH OF THE ISLAND.

If it were not that palmiras are so slow of growth, we should feel strongly inclined to advise our correspondent, the Pallai planter (see his letter), to leave the plants to grow amongst the coconuts. There would then be a valuable sugar, fibre, and timber yielding property to fall back upon, when the coconut palms had passed from maturity to decay, which we suppose they are likely to do at an earlier stage of existence in the Northern portions of the island than in the Western and Southern? This is just one of those cases where the practical experience of a man like Mr. Jardine would entitle him to be heard with respect,—at home as he is in coconut, cacao, cinnamon, coffee and tea culture. We fancy he would say, "If the palmira plants must be sacrificed, so as to give the coconut palms full room and nutriment, and if there is danger of grubs, burn all save the leaves, and bury leaves and ashes round the roots of the coconut palms." This is our advice, if there is no doubt of the superior value of a coconut grove of 70 trees to the acre, to a dense forest of palmiras at the rate of several hundreds to the acre.

But the letter of our correspondent gives us a new idea of the ease with which the Forest Department could grow palmiras over a large portion of the northern districts of the colony. We suppose the jungle from which our correspondent's estate was formed is a fair specimen of the forest generally. If so, vast tracts of jungle are filled with

"waddlies" the results of palmira fruits carried away by elephants, monkeys, bears and other animals. If such be the case, all that the forest officers have to do, to produce large expanses of palmiras, is to clear away the forest trees, a large proportion of which are not in the region we are referring to, of much value for timber purposes. For good palmira timber for housebuilding purposes, there will be ever a demand, locally and in India. The "waddlies" scattered in the northern jungles ought, therefore, to be cherished and where necessary added to, so that forests of this fine and useful palm may be ultimately available for management by the Forest Department, or for sale or lease to natives. The matter is surely well worthy of serious consideration.

MR. ROGIVUE'S MISSION AND THE MOSCOW EXHIBITION; CEYLON AND INDIAN VS. CHINA TEAS.

London, Sept. 11th.

No news having reached the Ceylon Association in London as to Mr. Rogivue's proceedings, a call was paid by me in another quarter in the hope of obtaining the information respecting the success or otherwise of his venture at the Moscow Exhibition in which your colonists have no inconsiderable stake. But although much was mentioned to me of a satisfactory character relating to the prosperity of Mr. Rogivue's general undertaking, it was told me that the London Agency of that gentlemen had not to date heard anything as to what had been done at the Exhibition at Moscow. No doubt Mr. Rogivue is waiting till the Exhibition there finally closes before venturing upon any statement as to what has been accomplished at it. But as regards the general trading carried on by your representative in Russia, this would appear from all accounts to be possessed of a most satisfactory character, and the weight of the consignments made from London in response to his demands have gone far towards determining this. We read so little now in the papers as to what is doing at the French Exhibition in Moscow, that we cannot even learn if the attendance at it has at all approached the estimate of this formed when the idea was first started.

From the best authorities we hear that Mr. Rogivue is so satisfied with the results to his tentative work that he is about to take a partner, in order to enable him to further extend his business. This fact would seem to augur well for the increase of the Russian trade in Ceylon tea; though Mr. Rogivue has himself stated that it has been very uphill work so far. The fact must, however, always be borne in mind that that gentleman is of a most sanguine temperament, and that this should cause all his reports to be received with some degree of caution. Indeed those who are best acquainted with him here tell me that over-sanguineness is Mr. Rogivue's only fault.

A good deal has been written to the papers lately as regards the reasons for the continued supersession by Indian and Ceylon tea of the China varieties, the returns continuing to show a large diminution in the import of the last for the past half-year. The *North British Daily Mail* of September 4th contained the following paragraph:—

TEA—CHINA, INDIA AND CEYLON.—Consul Gardiner thus summarises the advantages of the Indian and Ceylon tea growers:—1.—Command of capital. In India and Ceylon tea estates are generally owned by companies which can afford to carry on business at a loss of time, can purchase expensive machinery and plant, and can spend large sums of money on experi-

ments and on investigating the tastes and requirements of purchaser. 2.—The Indian tea grower can borrow money at from 4 to 5 per cent, while the Chinese tea grower has to pay from 20 to 30 per cent. 3.—In India and Ceylon the land tax is lighter than in China, and there is absolutely no likin, octroi, or export duty to pay. In China the likin and export duty often amount to 80 per cent of the selling price of the tea abroad, and to 100 per cent of the prime cost of its production in China. 4.—Labour is cheaper in India than in China. 5.—The tea planters in India and Ceylon have the necessary knowledge of chemistry and chemical agriculture at their command to produce in the tea by cultivation and manufacture the qualities required by the purchasers, and can vary them with the varying wants of different countries and districts. 6.—Better acquaintance with the tastes and requirements of purchasers, and intimacy with the retail dealers and their mode of conducting business.

Consul Gardiner's name seems to be unknown to the Ceylon men with whom the foregoing article has been discussed by me, and it is evident from that article that he is without acquaintance with some, at least, of the points which he touches upon. Thus, he speaks of a land tax in Ceylon, being ignorant evidently that such a tax does not, as yet at all events, exist in Ceylon. At the same time no doubt many of the facts Consul Gardiner has stated are correct and operative towards the conclusions he has made public. But there is another very vital condition upon which he has kept silence, and this has been given prominent notice in the *Engineer* which lately published an editorial dealing with the advantage of curing tea by machinery. The argument of this latter paper is that in China the tea is not only contaminated by contact with both the hands and feet of the natives, but that these prepare it in such small lots that it does not get into the possession of the native dealers until much of its strength and aroma has been lost by exposure. In Ceylon and India, the article points out, contact with the human hand closes with the plucking of the leaf. Machinery then enables a quantity sufficient to constitute a shipment to be turned out quickly which is packed into the boxes in a warm state as it finally leaves the machinery, and the strength and aroma are thus both preserved. This fact, the *Engineer* contends, may well account for the superiority in strength assigned to the teas of India and Ceylon as compared with those of China.

If we combine the causes assigned by Consul Gardiner with those stated by the *Engineer*, we doubtless obtain all those which have induced the British public to show the preference it has done for the teas exported by yourselves as well as for those grown in India over those of Chinese growth. The chemistry of tea-growing is, as we have learned of late from what Mr. Hughes has told us, still a knowledge too much in its infancy to have had the strong effect assigned to it by Consul Gardiner. That much as to this remains to be ascertained is certain, and the sooner the further experiments proposed by Mr. Hughes are carried out, the better it will be for all Ceylon tea planters.—*London Cor.*

WORLD'S FAIR MINING NOTES.

One of the greatest attractions of the mines department of the Exposition will be the remarkable collection of minerals owned by Professor A. E. Foote, of Philadelphia. He has the finest private collection in the world. It is a complete history of mineralogy, and it will be so arranged at the Exposition that the mineralogy of the States can be shown. This collection was shown at the Centen-

nial, at London, and at Paris, and in each instance received the highest award. It comprises about one hundred and fifty tons of rare minerals, and the exhibit occupies 6,000 square feet of space. At the Chicago Exposition one of the pavilions for this exhibit will be made of glittering mica, which will be procured in South Dakota. Among the additions to the collection is a mass of meteoric iron, weighing 230 pounds, which the professor found in Arizona recently. He sent a specimen of this to Professor George A. Koenig, of the University of Pennsylvania, who discovered in it black diamonds visible to the naked eye. This discovery is new to mineralogists and of great interest. In 1888 a meteor fell in Russia, in which the scientists discovered microscopic evidence of diamonds, but this Arizona meteor is the first to show the diamond formation to the eye.

Professor Foote will also show some entirely new copper specimens from Arizona, and a stalagmite tree, formed by limestone drippings from a mine in New Mexico. He will show the big garnets which he collected in Colorado, some of which are perfect specimens and above six pounds in weight. He has recently collected the finest specimens of celomanite ever found. In the professor's collection are all of the gems, rough and cut diamonds, rubies, topazes, opals, etc. His collection from the Pacific coast of America shows the wulfenite, a rare species of orange-red crystals; the brilliantly red vanadinites, and bright crystal of azurite, associated with velvet tufts of malachite. Alaska shows the deep red garnets, in their dull coats of mica schist. There is silver ore from the famous Bridal Chamber in New Mexico. It is said that a space the size of a bed-room, in this mine, produced \$500,000 worth of silver. There is a precious turquoise from Los Corrillos, New Mexico, where Montezuma got his precious chalcubutite, which he valued above gold. There are blends and galenas from the zinc region of Lake Superior. From the North Atlantic coast region is shown rhodonite, in fine crystals which is much used by the Russians in ornamental work. From the New Jersey mines come minerals found nowhere else in the world—franklinite—named after the philosopher—anomolite, troosilite, blood red zincite, etc. The South Atlantic coast region shows amethysts, sapphires, aquamarines, uranolate, etc.

In its exhibit at the World's Fair the government geological survey will place on view a sort of synoptic picture of the mineral resources of this country. Big chunks of native gold and silver will be shown just as they were dug out of the earth, together with remarkable ores of all sorts, particularly those of what are called "economic minerals," such as iron, copper and tin. Accompanying these will be maps drawn for the purpose of assisting the illustration. Several skilled collectors are soon to be sent out with instructions to gather in everything in the mineral line that is worth displaying. Professor Clarke, the distinguished chemist and mineralogist, has been given charge of the whole matter, and he is getting together a wonderfully fine assemblage of precious and semi-precious stones also, which will form part of the display. This collection, although it will be largely composed of gems found in the United States, will not be limited to those. Dozens of big boxes and trays full of such jewels of all sorts are at present being set in order for the purpose at the national museum. There are topazes, emeralds, rubies, diamonds, opals and every other kind of beautiful sparkler. Also there are so many curiosities, such as metals compounded in rare fashions in nature's laboratory—for example, bromide of silver and crystallized carbonate of copper. Examples will be shown illustrating the strange rules by which crystallization takes place, one metal or mineral assuming a certain geometrical shape another some different one, and so on. In addition to all this there will be relief maps, transparencies and photographs of American scenery. This will include most important views in mountainous regions, great deserts and other remarkable localities of interest from a geographical point of view. Photography in this line has been made a specialty

by the survey, which possesses a great collection of such works of art. If there were more money to spend it is probable that visitors at the Fair would have a chance to see some of the enormous fossil reptiles of the past, which Major Powell's bureau has been digging up during the last nine years; but presumably only pictures of them will be shown.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Sept. 12.

ARCA NUTS have been very scarce lately. A parcel of 47 packages has, however, arrived this week.

CINCIONA.—At bark sales on Tuesday a very small quantity of cinchona bark was offered—in fact the auction was one of the smallest on record. The catalogues comprised, of—

	Pkgs.	Pkgs.
Ceylon bark ..	689 of which	544 were sold
East Indian bark ...	403 "	388 "
South American bark ...	116 "	— "
Jamaica bark ...	2 "	— "
Total ...	1160 "	932 "

With the exception of a few parcels of Indian Crown bark, there were very few lots of good quality among the barks of Eastern growth. The supply of South American Callisaya also comprised some rich parcels, but all of this was limited too highly, and not a single bale of this kind was sold. There was a fair amount of competition, and the unit remained stationary at an average of 1½ per cwt.

The following are the approximate quantities purchased by the principal buyers:—

	lb.
Agents for the Messrs. and Amsterdam works ...	75,378
" Brunswick factory ...	35,021
" Italsan and America works ...	29,176
" Frankfort O/M and Stuttgart works..	24,172
" Auerbach works ...	12,163
Messrs. Howards & Sons ...	8,367
Other manufacturers ...	5,569
Sundry druggists, &c.
Total quantity of bark sold ...	180,603
Bought in or withdrawn ...	48,967
Total quantity offered ...	236,770

At the last Amsterdam auctions, which were held on the 3rd inst., 248,700 kilos. bark were offered. Of this quantity manufacturers purchased 192,812 kilos, equaling 8,995 kilos. (317,254 oz.) quinine sulphate. Sundry druggists bought 26,781 kilos. bark, and 35,180 kilos, representing 1,448 kilos. sulphate of quinine, remained unsold. The following were the purchasers of the principal buyers:—Auerbach factory, 58,190 kilos. bark; Powers & Weightman, 48,681 kilos.; Brunswick works, 37,775 kilos.; Böhringer & Sons, 35,095 kilos.; Frankfort & Stuttgart works, 24,142 kilos.; Tilliodier, 10,829 kilos.; Howards & Sons, 1,474 kilos.; and various buyers, 6,462 kilos. bark.

IMPROVING WORN LANDS.

Major Howard Swineford read a paper on this subject at a Southern institute. Among other things he said as regards green manuring. The practice of growing crops for the purpose of ploughing them under to fertilize the soil is one that, in my opinion, has a very much greater advantage than any other, and there is no better way of cheaply improving it than this. To procure a sufficient supply of manure in at the best a very costly process, but a crop that may be easily grown in a few months and then turned under may furnish to the soil as much fertilizing matter as eight or ten tons of manure per acre and this process may be repeated several times in one year. Manuring with green crops is not only the most economical but, to most lands, one of the surest and most speedy means of improving the texture and fertilizing properties of the soil. Besides furnishing plant-food the soil is made more mellow and better fitted for producing other crops. Various crops are used for this purpose, some of course are more valuable than

others. If we may be permitted to place two at the head of the list as most valuable, we would name red clover and the cow pea, the former for general use and the latter as best suited to this locality. Among the numerous crops used for this purpose are, buck wheat, rye, oats, corn and millet. The Hon. George Geddes, well known throughout the United States as a practical and scientific farmer, says of the clover: "If our soils require improving, we turn the clover crop under and repeat the operation until there is sufficient fertility to allow us to carry the clover off. The oftener we can fill the soil with roots and then plough them under and thus allow them to rot, the sooner do we expect to get our land in condition to bear a crop of grain. A very considerable part of the cultivated land in Central and Western New York has never had any other manuring than this clover and gypsum, and its fertility is not diminishing." He states that he had a field which for 74 years had been manured with nothing except clover grown upon it and ploughed in, and that this field had produced wheat, corn, oats, barley and grass. The clover thus used had, for 50 years, been regularly treated with gypsum, and that the land was constantly increasing in fertility.—*Indian Agriculturist.*

THE CEYLON TEA TRADE:

HOW IT IS OUTSTRIPPING THE COMMERCE OF CHINA.

CURING THE LEAF BY MACHINERY.

HOW THE FAILURE OF THE COFFEE FIELDS IN THE ISLAND LED TO THE ENTRANCE OF THE ENGLISH PLANTERS INTO COMPETITION WITH THE GREAT CHINESE MONOPOLY—THE MONGOLIANS GREATLY ALARMED—SOME COMMENTS ON DR. BEDLOE'S RECENT LETTER.

The reader of Dr. Bedloe's interesting letter on tea, which appeared in the "Times" of the 25th of July, will find certain statements which might be misleading, though much of the information volunteered is only too true. The present writer, a tea and coffee planter of ten years' experience, knows well that it is a fact that tea unfit for use is shipped from China to America. But the fault lies with the American consumer for refusing to pay for a good tea, or, to go deeper in the matter, it lies with the government for allowing inferior teas to be imported. The China tea trade among the lower end, I regret to say, even among the middle and intelligent classes, is demoralized by the "present" or "gift" system referred to by Dr. Bedloe, and this also ought to be stopped by legislation. Tea as an article of diet, ought to be prepared, bought and sold intelligently; not adulterated to sell, sold as adulterated, and bought in the glare of electric lights, fancy glassware, dinner sets or silver spoons.

Green teas ought to be avoided as impure. No tea can look green and be pure. Place any green leaf on the stove in your kitchen. Does it remain green? Of course not; and to keep its clear artificial coloring matter must be rubbed into the leaf after rolling. Moral: Drink black tea, or at least try and educate yourself to do so.

It is useless to quote in full all the appeals made to the Government to stop the importation of teas "too vile to drink." Dr. Bedloe's predecessor sent a dispatch to the Secretary of State in July, 1880, calling attention to the inferior quality of much of the Amoy Oolong tea exported to the United States and advocating protection for the American public.

Allowing, however, that much, very much, of the China tea imported is below the standard of good tea, Dr. Bedloe can scarcely speak with authority when he says there is no fine tea in America. There are not a few gentlemen in this city in old established tea houses who must consider this statement just a little rash. Good houses import "fine" teas which are sold at such prices as Dr. Bedloe quotes, and I have no doubt they would be all very well pleased to sell nothing else if the American people would pay for quality and

drink "fine" tea. So much for China tea. Now for "the Britoo." "The bold Briton permits patriotism and his purse to guide his palate and uses the vitriolic horrors of Ceylon and India." Now is this so?

Not many days previous to Dr. Bedloe's departure I had the pleasure of meeting him at the Philadelphia Sketch Club, and as he is one of my oldest customers I listened with pleasure to his outcries on that vitriolic horror, Ceylon tea. Now, alas! Formosa Oolong at \$50 per pound reigns supreme with him, while Ceylon "vitriol," lately sold at \$125 per pound in the London market, is the memory of a depraved taste. And this brings me to the history of Ceylon as a tea-growing country.

When I first went to Ceylon in July, 1876, a few acres of tea might have been found and pointed out as a curiosity. It was then of no value. Looking from my verandah in Dimboola I could view a "sea" of coffee, green, healthy-looking and bearing one of the heaviest crops known. Today, from the same spot, not a coffee bush can be seen, but only tea! tea! tea! A deadly fungus, attacking the coffee leaf and causing it to drop off, has caused this change. Old King Coffee has gone and Tea reigns in his stead. The old coffee store has become the tea factory, the bagful of ripe red "cherry" coffee is seen no longer; the basketful of green tea leaf has taken its place.

No sooner was it known that coffee was doomed than the Ceylon planter put his shoulder to the wheel and began to change the face of the country and to alter its staple from coffee to tea. This resulted in the most astounding success in the annals of "extensive" cultivation.

Tea is a shrub indigenous to India—not imported from China. It is planted out on the estate generally as a small nursery plant, in line and at measured distance from its neighbors. It grows at any elevation, but quicker at a low elevation. I have known tea grow higher in one year than I could reach at a low elevation, while in the high districts it would take two or three years to attain the height of say six feet. When fully matured it is pruned down to twenty inches, the result being a flush of young wood. This is what is wanted for "leaf," but to allow the bush an opportunity to give us a surface to pluck from it is left for a time. The leaf is then plucked, not from the sides, which increase the surface, but the top. Two leaves and a half are used for manufacture, these lower down being considered too coarse.

In plucking, we have three grades of tea, viz., the terminal leaf bud, and the very small leaf, called "Flowery" or "Orange" Pookeo. Then comes the medium leaf, called "Pookeo," and lastly the largest and coarsest, called "Pookeo Souchong." All are plucked and put in the basket indiscriminately to be sifted out after manufacture.

Twice a day the baskets of tea leaf are taken to the factory and spread out thinly on canvas to wither, that is, become soft and pliable.

The leaf thus spread out in the evening would be ready for rolling next day. It will be observed from the above illustration that the withering takes place in the interior of the factory, not in the sun.

When sufficiently withered the leaf is lot down through a funnel into the "roller," which has taken the place of the hands and feet of the great unwashed.

This machine consists of a receptacle for the leaf, on which pressure is automatically applied. The rolling surfaces, which move at right angles to one another, but appear by a peculiar crank motion to be revolving, are made of wood, so that the tea leaf does not come in contact with any metal.

The tea when rolled is received in a trolley from the bottom of the machine and appears like cooked spinach and green. If fired immediately it would be a pure green tea and would in process of firing turn black. It is, however, laid thickly on a table or in drawers for a season to oxidize, and in an hour it will have commenced to turn from green to a bright brown color. This is a matter which requires careful attention, as over fermenting or under fermenting

alters the flavor entirely. Only the practiced eye can decide, and it decides at a glance, when the tea is right. When it is comes the firing. Several machines have been invented for this purpose, but I presume the siccoco is the one most commonly used. This is a machine which looks like a very large T, and is known as the T siccoco. Along the top are trays upon which the leaf is spread thinly. Below is the furnace and hot air pipes heating, if I remember right, to about 180 degrees. Two coolies tend the machine—one at each end—and pass the trays through until it is black and crisp.

Now comes the classifying of the tea. Three grades have to be separated, and this is accomplished by sifting by hand or machinery, as the case may be. Through the fine sieves we get the fine Flowery Pekoe, next size the pekoe and the large leaf remains, all being cleaned and dusted before packing.

This completes the process of manufacture. There has been no adulteration of any kind, and all the operations have been performed in a factory so clean that one might almost eat his dinner off the well cemented floor. No smoking is allowed, nor is anything permitted which could possibly contaminate the precious leaf.

Therefore, in spite of Dr. Beddoe's denunciation of Ceylon and Indian tea (the latter being equally carefully cured) does not the cleanly process of curing under European supervision commend itself over the Chinese method? It certainly has commended itself in English eyes, as statistics show. In 1878 the exportation of tea from Ceylon was 25,000 pounds; this year the estimate is 61,000,000 pounds, while the consumption of China tea in England fell from 125,000,000 pounds in 1879 to 61,000,000 pounds in 1889.

Such an alteration in trade has so alarmed the Chinese that fully five years ago the Chamber of Commerce at Shanghai sent a commission to Ceylon and India to investigate. The commissioners returned with the warning that if China did not send better and purer teas from her shores and open her gates to the foreigner with his machinery, she must eventually lose her export trade. It is to be hoped that China and Japan will one day tear down these walls of conservatism and open their gates to scientific and modern appliances for the cultivation and preparation of tea. Their export trade is even now in extremities.

J. McCOMBIE MURRAY.

—*Philadelphia Times*, Aug. 9th.

In the American paper in which the above article appears, it is illustrated by engravings of the "Tamil girl plucking leaf," "Bringing in leaf," and "Withering."—*Ed. T. A. J.*

POISONING BY A "WEED-KILLER."—An inquest has been held at Hastings, touching the death of a domestic servant. It appeared from the evidence of the employer, that the girl was taken ill, and that he was informed that she had drunk some liquid he had purchased as a "weed-killer." The "weed-killer" he had purchased in the afternoon of the day on which deceased was taken ill, at Mrs. Gilbert's, florist, in Queen's Road. The bottle produced, which labelled "Scotch elder-wine," and also bore a smaller label with the words "weed-killer," was taken by himself to the shop, and the liquid, about a pint, was supplied in it. He had himself labelled it "weed-killer." After he had used a portion of the liquid, he left the bottle with the remainder in a corner of the garden, with the label "weed-killer" facing outwards. Deceased told him in the presence of the doctor that she had taken some of the liquid. He had never used the liquid before, and he was not and did not know that it contained poison, there being many things that are not poisonous which would kill weeds. The sister of the deceased deposed to seeing the bottle on the kitchen-table, and afterwards finding the deceased spitting over the sink. In reply to her inquiry, deceased said she thought the liquid in the bottle was elder-wine, and that she had tasted it, but was certain she had not swallowed any. Mr. E. J. Adkins, surgeon, said that he had analysed the contents of the stomach, and found no arsenic, but had detected it in other parts of the body. He had examined some of the "weed-killer," and found it contained a great deal of arsenic, caustic soda, and

methylated spirit. The symptoms observed were consistent with arsenic poisoning. Ernest Burton, assistant to Mrs. Gilbert, florist, said he served Mr. Banks with the weed-killer, and told him how to use it, and Mr. Banks put the label on it in the shop. It was Smith's weed-killer, but although he knew it was a poison, he did not know what it was made of, nor that it was such a deadly poison. His employer purchased it in gallon cans, which were labelled "poison," but as Mr. Banks bought so small a quantity, he did not think it necessary to put on a label. He had never sold less than a gallon before, and when he sold that quantity a label, supplied by the manufacturer, and describing the liquid as a poison, was put on. The coroner said the death appeared to have been the result of an accident, but it was doubtful whether a florist had the right to sell such a liquid. By the Poisons Act, no poison other than a chemist was allowed to sell arsenic, and the seller was liable to a penalty if he sold it without making an entry of the sale in his book, and labelling the bottle containing it to show that it was a poison. The jury returned a verdict of death by misadventure, and expressed the opinion that more care ought to have been exercised in the selling of a liquid of such a poisonous nature.—*Gardener's Chronicle*.

CEYLON PINEAPPLE PLANTS FOR NATAL.—Mr. J. Medley Wood, curator of the Berea Botanical Gardens, stated in a report:—

The growth of fruit suitable for the Johannesburg market and for export, is becoming a matter of some importance, and I have been applied to by different growers to introduce in quantity the pine known as "Providence," as the fruit of the variety we have here does not appear to be large enough for export, one of my informants stating that fruit of the smooth-leaved variety had realised in Johannesburg double the price of our common pine. I therefore wrote to the Director of Kew Gardens for information on the subject and in a reply just received Mr. Morris says of the "Providence":—"It is a large-fruited kind, largely grown for export purposes. We have no special facilities for getting suckers of it. No doubt your Government could manage to obtain suckers from the Government of the Bahamas, and have them shipped direct. It would be needless to introduce them in small quantities. You require two or three hundred at least. There is an equally fine and large pineapple grown in Ceylon and Singapore. In the former it is known as the 'Queen' pine. It is quite as large as the Providence pine. You might obtain suckers of those, perhaps, more conveniently than from the Bahamas. As regards flavour and appearance, there is nothing to choose between them." As the pine we have in Natal has always been known here as the "Queen," I wrote to Mr. A. H. Bisset, who has been a resident in Ceylon, and he says "I do not know the Ceylon pine called the 'Queen,' unless it is a pine with small smooth leaves, running to over 10lb. in weight, yet of good flavour and consistency. This pine I have heard called the 'Kew' and sometimes the 'Mauritius.' Apart from this pine, which is a splendid one, almost square-shaped, with large base, I only remember the common pine, which is, as far as I can distinguish, the same as we have here." Mr. Bisset also tells me that steamers leave the ports of Ceylon for Madras several times a week; if therefore, the suckers were shipped so as to catch one of Messrs. King & Son's steamers, they should, if well packed, arrive here in good order. Messrs. A. M. & J. Ferguson, of Colombo, would no doubt be able to procure the suckers if favoured with instructions. We have in the Gardens one, or perhaps two, species of what are called the smooth-leaved pine, or, as I have heard it called, the "Cayenne." They have not done well with us; but I have directed the gardener to remove them to a more favourable situation and, shall observe them more closely during the season. I am writing to Dr. Trimen of Ceylon, on the subject; but the question of importing suckers in quantity, of say 2,000 to 3,000 is a matter to be dealt with by the Committee. Exchanges of plants between here and West Indies are stopped on account of the outbreak of coffee disease in Natal.

PHYLLOXERA.—M. Rommier has ascertained that a solution of bisulphide of carbon, in the proportion of O, 4 gramme, to a litre of water, suffices to kill the Phylloxera as well as their eggs.—*Gardeners' Chronicle.*

PROTECTION IN FRANCE.—The horticulturists of Angers have protested energetically against the protective duties proposed to be laid on plants entering France from foreign countries. The imports of trees, shrubs, and plants into France amounted in value in 1890 to 1,685,900 francs, 1,200,000 francs of which went to Belgium, while the value of these exported amounted to 2,875,000 francs. French horticulture, say the protestors, needs no protection, and demands none. Some few French firms, ten in number, have entered into competition with the Belgium and the English, but with little success, and hence they demand protection. Is it just, ask the signatories of Angers, that a small number of establishments shall be advantaged at the expense of the large majority? But this is precisely what Protection does all the world over.—*Gardeners' Chronicle.*

CONSUMPTION OF COFFEE AND TEA IN THE UNITED STATES.—It is time Mr. Elwood May commenced his crusade in favour of tea in earnest, for the figures for 1890-91 are by no means encouraging. The per capita consumption was only 1.32 lb. against 1.49 in 1887, a material decrease; and the *American Grocer*, from which we quote two interesting articles, states that cheapness is not increasing consumption. The total consumption was less than 83½ millions of pounds, and there was a slight decrease on the previous year. The figures for coffee are very different: 8.24 lb per capita, the total being 519½ millions of pounds. But most melancholy and alarming is the contrast of the enormous alcoholic drink bill of the United States. The money cost is about \$900,000,000, against only \$150,000 for tea and coffee. There is much room for further temperance efforts in the United States, and but little hope, we suspect, for the advocates of prohibition.

IMPORTS OF TEA.

The imports for the fiscal year ending June 30th, 1891, were almost abreast of those for the year preceding, as the following official statement shows:

Year ending June 30—	Imports Pounds.	Value. Dollars.	Average cost per lb. Cents.
1891.....	83,453,339	13,828,993	16.5
1890.....	83,886,829	12,317,493	14.6

The value of the tea trade is less than one-seventh that of the coffee trade, and both combined about one-tenth the liquor trade, and one-fourth the beer business. For beer the United States pays at retail \$427,896,167 annually, as against an estimated retail cost of tea and coffee of \$150,000,100. Whisky costs the country, at retail price, \$395,233,029, the consumption in 1890 reaching 87,829,562 gallons.

All but 1,057,415 pounds of tea imported were consumed in the United States, representing a per capita import of 1.32 pounds, as against 1.33 pounds in 1890, 1.28 pounds in 1889, 1.40 pounds in 1888, 1.49 pounds in 1887, 1.37 in 1886. Evidently cheap tea is not inducing a freer use of the leaf.

COFFEE IMPORTS IN THE UNITED STATES.

The imports of coffee into the United States for the fiscal year ending June 30th, as reported by the United States Bureau of Statistics, compare with the previous year as follows:—

	Imports Pounds.	Value Dollars.	Average cost per pound. Cents.
1891 ...	519,528,432	96,123,777	18.5
1890 ...	490,159,120	78,267,432	15.6

The figures show an increased importation of 20,369,312 pounds and an average cost of 3.1 cents per pound above the average for the preceding year. The United States coffee bill last year was nearly one hundred millions, of which Brazil gets three-fourths. Planters have been getting two prices for their product

and growing rich remarkably fast. Taking the Government return, the only one showing the total imports at all points, and we have the following statement showing the consumption:—

Year ending June 30th, 1891.	Pounds.
Imports ...	519,528,432
Exports ...	8,486,973

Net imports or consumption... 511,041,459

This represents a per capita consumption of 8.24 pounds against 9.61 pounds in 1885, a year of low priced coffee, the average import cost being 81 cents.

The following table shows the net imports, value and per capita imports of population for the ten years ending June 30th, 1891:—

Year—	Net Imports Pounds.	Value. Dollars.	Per Capita Populat'n.
1882...	435,679,239	42,815,027	8.30
1883...	478,507,125	88,155,251	8.91
1884...	508,632,863	46,955,394	9.26
1885...	539,264,856	43,389,270	9.61
1886...	537,211,741	40,145,304	9.36
1887...	500,810,537	58,416,200	8.53
1888...	408,562,775	58,670,737	6.81
1889...	461,132,100	72,139,897	9.16
1890...	590,161,900	79,750,979	7.83
1891...	511,041,459	94,628,119	8.24

The above is an interesting study. From 1884 to 1887 there was an era of overproduction, larger imports, low prices and increasing consumption. This was followed by a period of poor crops, high prices and decreasing consumption. High prices have stimulated production and it now looks as if in two or three years more we would reach the point where supply would again overleap demand.

CYLON TEAS.—The quantity of Ceylon teas brought forward during the week has again amounted to over 20,000 packages, but the market has improved, and a large business has been done in the country. At this time last year such a supply as this would inevitably have depressed the market considerably, but the consumption has increased so rapidly, that even this large quantity is not too much, if actually sufficient, for requirements. Prices have again been higher for every grade, this being well exemplified by common teas, which are ½d to ¾d dearer than a fortnight since, and all other grades have participated proportionately in the advance. The late improvement in quality has been maintained, and Ceylon is by far the cheapest tea on offer.—*Produce Market's Review*, Sept. 5th.

ESSENCE OF COFFEE.—In the annual report of the Glasgow Sanitary Inspector (Mr. Peter Fyfe), issued last week, the following item occurs:—“Essence of coffee is a manufactured article of diet which I deemed it advisable to inquire into this year. It is much advertised by the vendors, and is, I believe, largely purchased by the public. I took three samples of this essence, as manufactured by the three principal makers, and sent them to the public analyst. As it appears to me to possess public interest, I give here the results of his analysis in each case:—

	1 Per cent.	2 Per cent.	3 Per cent.
Caffeine ...	00.22	00.18	00.15
Cane Sugar ...	41.00	33.85	56.95
Fruit sugar and other org. nic matter ...	19.43	29.03	11.22
Mineral matter in ash ...	1.52	1.42	1.32
Water ...	34.62	35.52	30.35
	100.00	100.00	100.00

His notes attached to the certificates show that the caffeine in the samples is very low—in No. 3 absurdly low—and the analysis of the best one shows that 98½ per cent, of this concoction is water and sugar.—*Chemist and Druggist*, Sept. 12th.

THE BERMUDA JUNIPER.

The principal tree of the Bermuda flora is the Juniper, which covers the islands and makes the conspicuous feature of their vegetation. A few other trees grow naturally on these islands, and several others have been carried to them by man and have now become more or less firmly established. No tree but the Juniper, however, makes much show on the islands, which, from a distance, seem to be completely covered with it.

This Juniper has been growing on Bermuda for a long time. The wood, in the condition of lignite, was found at the depth of fifty feet below low-water mark during the dredging operations undertaken by the British Government in connection with the building of the Bermuda dry-dock. Subsidence of land is slow unless it is the result of some violent catastrophe, like an earthquake, and the fact that this Juniper grew on ground which is now far below the surface of the ocean is conclusive evidence that it has occupied these islands for a period so long that the mind of man, accustomed to measure time by years or by centuries, cannot form a clear notion of its immensity.

How did the Juniper first get to Bermuda? By what process did this tree, which is unlike other trees of its kind, first appear on these minute islands remote from all other land, and raised from the bed of the ocean by the patient toil of insects, long after the neighbouring continent had assumed very nearly its present aspect? These are questions which present themselves to the student of nature as he sails into the harbour of Hamilton and sees the low islands about him everywhere clothed with this peculiar tree. It was not a case of separate creation, for the idea of the old philosophers, that plants and animals were created as they now appear in the different parts of the world where they occur, is no longer tenable. Man certainly did not bring the Juniper to Bermuda, for it is not quite four hundred years yet since man first saw these islands; and it is not improbable that trees are still standing which were growing when Juan Bermudez sighted the islands which Oviedo, the first naturalist to write on the New World, and a passenger with Bermudez on his ship "La Garza," described as "the most remote of all the islands yet found in the world."

Fifty years ago these questions would not have been easy to answer. Now the light which Darwin and Hooker and Wallace and other naturalists, working on the lines laid down by Darwin, have thrown on the origin of insular floras makes it easy to find a simple and, probably, a correct solution of the presence of the Juniper on the Bermuda islands. There is a Juniper in North America growing in nearly all parts of the continent, from Canada to Florida, and from Cape Cod to Vancouver's Island; this is our so-called Red Cedar (*Juniperus Virginiana*), a tree which, in all important respects, is very similar to the Bermuda tree. It is a well-known fact that several of our birds are very fond of the berries of the Red Cedar and devour them in large quantities. To this is due the fact that this tree is so generally scattered and multiplied through the country, as birds void the hard stone-like seeds without injuring their vitality, and so spread them far and wide. There is evidence enough that our Red Cedar was growing on this continent long before Bermuda rose above the surface of the ocean; and a bird, with his crop full of Cedar-berries, may have been blown off from the mainland and found a resting-place on the then barren coral rocks, where the seeds he had brought found conditions which favored their germination. Our continental birds, in several species, now visit Bermuda every year in considerable numbers, and this habit must have had its origin in accident. The Red Cedar once established in Bermuda, it is easy to imagine that the climate and soil conditions of its new environment would gradually change its appearance, just as all plants are gradually modified by the influences of their surroundings; and that in time, after

the lapse of countless years, that it would take on its present appearance and stand for what naturalists call a species, that is, a modified or differentiated form of some other form or species. And, after all, the differences which distinguish the continental Juniper from its insular descendant are not very great. The branches of the island tree have grown stouter and tougher through their long struggles against the ocean gales; the roots have learned the secret of holding on to bare rocks or of penetrating deep into their interstices. The foliage has lost its dark green tints and is now a pale blue-gray. The leaves are blunter and are furnished on the back with a gland or resin duct. The fruit is somewhat larger, and the heartwood is not so bright a red and is rather less fragrant than that of the Red Cedar.

An interesting thing about the Bermuda Cedar is its ability to grow apparently equally well in different situations. It flourishes on the dry porous limestone-hills and grows as freely on the brackish swamp-lands which occur in some parts of the islands. It is not unusual to find trees of a wide geographical range, and therefore subject to different climatic surroundings, which seek to adapt themselves to them by selecting situations which in one region are at the sea-level and in others are at the top of high mountains. Many conifers which grow at the north at the sea-level are found in the south only at considerable elevations above the Ocean; and the Red Cedar itself, which grows at the north on high dry uplands, inhabits, in Florida, swamps which are inundated during a considerable part of the year, and in the dry climate of the western part of the continent occurs only at high elevations. But the Bermuda Cedar grows as well in one place as it does in another, although climatic conditions do not, of course, differ perceptibly in different parts of this small group of islands.

Large individuals are no longer common; the axe of the wood-cutter and the ship-builder long ago swept them away. Here and there a venerable trunk may still be found, but among the large trees still growing on the island very few probably are much more than a century old or are large enough to possess any great commercial value. Formerly the wood was much used in ship-building; and it is interesting to note that Henry May, an English sailor, who was wrecked on the Bermuda Islands in 1593, and who afterward printed the first account of them, escaped with his companions to the banks of Newfoundland in a vessel which they were able to make from the Cedar-wood. This same wood, twenty-seven years later, furnished the material from which Admiral Sir George Somers, who the year before had been wrecked while in command of the "Sea Adventure" on the islands, constructed the vessel which carried him to the relief of the infant colony of Virginia, and in which his body was afterward borne back to his native land. Beautiful and very lasting furniture, too, was once made on the islands from the Cedar-wood, and old cedar chests and cabinets 200 years old and more are still held as heirlooms by the descendants of some old Bermuda families who still live in houses finished with this wood, which grows with ago rich and dark in color like old mahogany.

Two portraits of Bermuda Cedars are printed in this issue. That on page 274 represents the stem of a very old tree standing in the Devonshire churchyard close by the ivy-covered parish church, which resembles in architecture and surroundings one of the little churches of the older Devonshire. The tree, which recalls one of those venerable Yews of England, hoary with age, and familiar inhabitants of many an English churchyard, probably led to the selection of this particular spot as a place of worship. The tree must have been a very old and large one when the little church was built; it may well have been standing when human eyes rested on these islands for the first time, and probably it has changed very little in the last 200 years. The diameter of the trunk is now fifty-nine inches, and the height of the tree is some forty feet. Only two larger specimens are now known to exist.

The second view represents the tree as it grows in the moist black soil of the Devonshire marshes, a large tract of ground covered with Cedars of large size and springing from a dense undergrowth of Wax Myrtle,

or Myrica, identical with the species so common on our Atlantic sea-board, and of Baccharis, similar to, although distinct from, our sea-board species. Tall specimens of the Bermuda Palm which, next to the Juniper, is the most interesting plant of the islands, appear here and there among the Cedars, and the ground beneath the shrubs is covered with a luxuriant growth of Ferns—with the Bracken (*Pteris aquilina*) with fronds four or five feet tall, with numerous clusters of the great Marsh Fern (*Aerosticum aureum*), and with the rare and local Devonshire Marsh Fern (*Aspidium Capense*). These marshes and their inhabitants are very beautiful, more beautiful, certainly, than any other part of the islands, and as the sunlight plays through their open glades on the pale trunks of the great trees, they offer contrasts of color and afford effects of light and shade which our picture does not convey and which words cannot paint.—*Garden and Forest*.

OUR FRESH-WATER FISH AS FOOD—I.

(By WYVERN.)

Seeing that we possess in the rivers and tanks of Southern India several varieties of fish which, if properly treated, would form most certainly a valuable addition to our food, it has occurred to me that a few words on the subject may be useful. That the capabilities of our fresh-water fish—from a gastronomic point of view—are practically ignored by the majority of my fellow countrymen in India will, I think, be admitted. To many such food is distasteful on account of its alleged muddiness, lack of firmness, and the nuisance often caused by its numerous bones. Most, if not all, of the evils which cause these objections can be overcome with a little care, and I hope to show that many a tasty dish can be concocted with fishes which have hitherto been looked upon as not worth the trouble of cooking. It goes without saying that the observations I am about to make cannot be very interesting to those who live within immediate reach of the "harvest of the sea," or to whom sea-fish is brought by the railway. They are, of course, addressed most particularly to the large number of Anglo-Indian exiles who do not enjoy either of these advantages, to inspecting officials, tourists, and sportsmen, whose duty or pleasure takes them into remote districts, and obviously to those who live permanently at a distance from cantonments.

Mr. H. S. Thomas who, as everyone knows, has done yeoman's service to his brethren of the angle out here by his able instructions in regard to the capture of fish, gives in Chapter VIII of his less expensive work on *Tank Angling* a very complete résumé of their "names, description, and habit." This compendium should be studied carefully by all who desire to add fresh-water fish to their ordinary diet, for independently of the valuable information it affords us to the vernacular names of fishes it frequently indicates the varieties which possess a reputation for their edible qualities. I believe that I am right in saying that there is not much difficulty in obtaining fresh-water fish in this part of India. If the tourist be no angler himself, the chances are that there is a member of his retinue who can catch fish easily enough. Mahomedans are often clever fishermen, and among peons, watchmen, and pensioned sepoys you frequently find a man of this disposition. Netting is, of course, practised in all directions by the villagers, and in many places for a few annas a miscellaneous draught of fishes can without difficulty be brought into camp. Let us now see what can be done with them. Few men who have ever practised the gentle craft of angling have failed to read that most excellent work, *The Complete Angler*, by Isaac Walton, and Charles Cotton (1676); and in doing so must surely have observed the care with which the authors described the methods of dressing the various fish to the capture of which they devoted themselves. Their recipes, now more

than two hundred years old, can scarcely be improved upon, notwithstanding the advance that has been made in culinary science. In the first place, they continually insist upon the necessity of dressing fresh-water fish as soon as possible after capture, and there can be no doubt that this is correct notwithstanding a strange idea that some people entertain that salmon, pike, and certain other varieties of English fresh-water fish, are better if kept for at least a day. Another point is the speedy removal of the viscera. The fish intended for the table should be killed at the water-side at once, and then emptied, the liver alone being saved. It should then be wiped dry with a cloth, and sent up to the camp or bungalow forthwith with directions to the cook for its treatment. If large enough, fresh-water fish should certainly be crimped as soon as killed, i. e., scored with a sharp knife, transversely from head to tail, on each side nearly to the bone, the cuts being about two inches apart according to the size of the fish. A douche of the coldest water available should follow, and a plunge in the stream in a cool shady spot for a quarter of an hour. Crimping should be carried out before the fish stiffens. The process renders the flesh "firmer and crisper," (says Sir Humphrey Davy) "by preserving the irritability of the fibre," while the speedy removal of the intestines, and the grass and weeds, on which the fish has been feeding, from its throat goes far to destroy the mummy taste, and to nullify any unwholesome effect that may arise from the sort of food it may have been eating. Old Isaac inveighed very strongly against allowing a fish to soak in water after it had once been cleansed, pointing out that such a practice "abated much of its sweetness." Speedy cooking after cleaning was his maxim.

Boiling fresh-water fish is less to be recommended than baking, stewing, broiling, roasting, or frying it. Sir Henry Thompson shows in his admirable treatise on *Food and Feeding* that much of the nutritious element is lost by this process, notwithstanding that you plump the fish into boiling salt and water to secure as much as possible its juices and flavour. Nevertheless, it may occasionally happen that you have no other alternative. If so, remember the boiling salt and water. If instead of water you can prepare a *court bouillon* so much the better. This is a species of stock with vegetable flavouring and wine. For the stock I would use the trimmings of fish, heads, fins, tails, and any sort of fish that may on account of its boniness be considered to be beyond the pale of cookery. Onions, and any available vegetable, should be boiled with the fish, and a little white wine, such as chablis, sauterne, or hock, may be added. Instead of white wine a glass of claret can be used, and, if that be impossible, one of vinegar. In camp there may be difficulties in regard to some of the ingredients I have named, but the principles can be observed as far as possible. A bottle of dried sweet herbs ought always to be included in the camp store-box. In cantonments, of course, matters can be managed simply enough. If the supply of milk be cheap and plentiful, *court bouillon à la Nantaise* may be tried, i. e.—milk and water in equal parts, with pepper and salt to taste.

Baking can generally be accomplished by Ramasawmy in camp under difficulties that would petrify his European brother; roasting on the spit, too, he can manage successfully; while stewing and broiling cause less trouble than either of the two former processes, and may perhaps suit his appliances more readily. In camp there is, as a rule, no little difficulty in frying fish, for the medium can rarely be got in sufficient quantity. Ghee will probably be the only kind procurable, and if perfectly fresh and sweet this may be used for dressing small fry such as the *Chela argentea* (Tam: *Vellachee*), *C. dupeoides* (Tam: *Netteli*), the gudgeon, *Gobius giuris* (Tam: *Ulave*), and fillets of various fishes. Dipping in milk and flouring will be found far better than bread-crumbling, and bid your cook to be good enough not to spoil "the fry" by the condiments he loves to introduce when frying fish, the delicate flavour of which cannot withstand the interference of *turmeric*. For example, an old Anglo-Indian recipe for a "frying batter" propounds that

some garlic, onions, green ginger, and salt should be pounded and mixed with the flour of gram or dhal; to this tyre and turmeric should be added, and when sufficiently moist applied to the fish which should then be fric'd in ghee! Surely this elaborate preparation would disguise any fish completely. If you want to Orientalise fish for a change, curry it, or serve it as *môlé*. Filleting fresh-water fish is generally a wise proceeding. The Native cook performs the operation well, and you are thus protected as much as possible from swallowing bones, and the unpleasantness of catching one in your throat. All the trimmings which are left after this process has been carried out come in usefully for the stock required for the pie, stew, or sauce, as the case may be.

The Indian *murrel* (Tam. *Verarl*) may be likened to the English jack, and be cooked in like manner. Let him be carefully killed, and cleaned as hereinbefore advised. Do not boil him if you can avoid it. If under two pounds in weight *bake* him, if bigger than that *roast* him on the spit. In either case he must be stuffed, pike-like, and this preparation can of course be varied at pleasure. Experience seems to show that ordinary fish derive in cooking the greatest assistance from the essences of *shell-fish*. Thus oysters, shrimps, prawns, lobster, crayfish, &c., are most valuable in sauces and stuffings. Out in a "tanky" district you often can procure quantities of little fresh-water shrimps and cray-fish. With these well cleaned you can compose a very tasty stuffing, using bread crumb, eggs, the minced shrimp, a little anchovy sauce to strengthen them, a pinch of mace, salt and pepper. Suet or butter in the proportion of one quarter (or one-third if you can spare it) of the whole preparation is most essential, because it preserves the moisture within, so necessary to prevent the fish being too dry. Tinned oysters, and the liquor with them, can of course be used instead of the fresh-water shell-fish, or with them if the fish be very large. Here is a good receipt for baking a *murrel*. See that the fish is perfectly clean, and thoroughly dry before stuffing it. Take sufficient bread crumbs to fill the fish nicely without overcrowding, put them into a bowl, break into the bowl two, three, or more eggs according to the quantity of crumbs, which is of course decided by the size of the fish. The eggs when added should moisten the crumbs throughout. Add about a teaspoonful each of thyme and marjoram from the bottle, and enough chopped suet to represent one third, or not less than one quarter of the whole mixture, salt and pepper in proportion. Instead of suet, tinned butter can be used, or minced cooked fat bacon. Two or three anchovies, wiped free from oil, may be minced and added, or a slight allowance of anchovy sauce; if the liver of the fish has been saved it should be minced, and put in also. In deciding the exact amounts of these ingredients you must be guided by discretion remembering that the crumbs give bulk, and the eggs cohesion; that the suet, butter, or fat provides the necessary internal basting, so to speak, and the herbs, seasoning, and anchovy, flavour. Having thoroughly blended the whole composition like a pudding, fill the *murrel* with it carefully, sewing up the opening in which it is confined. If by chance you have made a little too much, the stuffing that is over can be divided into portions, cutlet-wise, and fried, to be served as a garnish. The fish having been thus prepared should now be set in the baking-dish (which should be well buttered) in a circular form, if liked, with its tail secured in its mouth; and thus far our proceedings are complete.

During the mixing of the stuffing and the arrangement of the fish, a broth should have been simmering on the fire made of fish trimmings, an onion, some herbs, &c. Any fish that may be superfluous—(assuming that several have been caught, and that after giving some away a few can be spared for the purpose)—ought to be used in this stock. As already mentioned, a glass of chablis, sauterne, or hock, if by any chance available, should be thrown in; or if no light white wine can be given, a glass of claret, failing that a sherry glass of vinegar. The stock is not required in very large quantity; about a pint and a half,—that is to say an ordinary quart bottleful,—will generally, unless the fish be very large, be found

enough. Use it in this manner:—Pour as much of it as will moisten the dish round the fish to a depth of about two inches. Put a little butter on the fish, and then set the dish in the oven. Baste it every now and then with its own liquor, and use your best endeavours to keep it moist. After about fifteen or twenty minutes' baking the fish will be done. Mix in a saucepan separately a *roux* with half an ounce of butter and half an ounce of flour; stir together over the fire for two minutes, then add a salt-spoonful of salt, a pinch of pepper, and a breakfast cupful of the fish stock previously made; now empty the liquor that may remain in the baking-dish round the fish into this sauce, boil one minute, add half an ounce of butter and stir till it is melted. Put the *murrel* carefully on a hot dish, pour the sauce over it, and serve. Be very careful in moving the fish; indeed, if you think that it may break during that operation, leave it alone, pour the sauce over it, and wrap a napkin round the baking-dish in which it should be served.

If the fish be over three pounds in weight it is well worth while to roast it. The preparations in regard to cleaning, drying, and stuffing are the same as those just described for baking. The operation of spitting, however, requires great care, for if carelessly done, and the fish be at all over-roasted, the chances are that it will fall off the spit, and break to pieces. To guard against this catastrophe you should make a cradle for the fish in this way.—Take four strips of thinly split bamboo, cut them a little longer than the fish, lay them in rows four inches apart, and tie across them, at intervals of six inches, four tapes as in the following diagram:—

The tapes, which are represented by the dotted lines, should be knotted to each strip of bamboo at the points of intersection. Thus you have a cradle large enough for a fish eighteen inches long, and a foot or a little more in girth. It is secured to the spit by the ends of the tapes, which are left over for that purpose. The arrangement is in principle something like the cradle which is placed round a horse's neck to prevent his tearing himself when under treatment for a wound. Having thus attached the fish securely to the spit the roasting should be conducted before a clear charcoal fire, and basting should be kept up continually. To facilitate this work, place a tin baking dish under the fish, put into it four ounces of butter, and when that has melted, a glass of vinegar; catch all the liquid that drops from the fish, and use this with the melted butter and vinegar for the basting. When done, detach the fish carefully, lay it in the hot dish prepared for it, and pour over it a sauce composed in the same way as that recommended for the baked *murrel*.

The recipes given for baking and roasting the *murrel* can be applied to several other fish:—the various carps and labeos, the *wallagu attu* (freshwater shark) &c., but very large fish are better prepared in fillets than whole, the treatment of which must form part of another article.—*Madras Mail*.

WONDERFUL TREES.

The subject of *wonderful trees* is an almost inexhaustible one, abounding in interest and curiosity. In our own State are found the most famous groves

of gigantic trees in the world, perhaps. One who visited the Mariposa Grove last year writes: "They are not trees at first sight. You can neither measure them with your eye nor sit in their shade—only take in a portion of the brown trunk as large as a good-sized house. It is only by an unusual effort of looking up that we see either foliage or limbs. They are not beautiful—simply enormous." Imagine one tree measuring 90 feet in circumference; this is true of "Grizzly Giant," "Wawona," sometimes called "Tunnel Tree," has a roadway cut through the solid heart which is 27 feet through, 10 feet high and 10 wide, and yet the tree is vigorous and growing. There are many others equally as wonderful in this famous California forest.

The cypress, in ancient times, was considered a sacred tree, and idols were carved from it. The Pacific Coast Indians were found using it in their ceremony of purification in their wildest savage state. The mulberry has been called the wisest of trees from the fact that it never puts forth its buds and leaves till the season is so far advanced that there is no inclement weather to be apprehended. Rose-wood is said to owe its suggestive name to the fact that when the tree is first cut the fresh wood possesses a very powerful rose-like fragrance. There are several varieties of this wood and all very valuable. The Quinquepinc oak at Woodbridge, Conn., which was cut in 1882, was pronounced the eldest tree on the Atlantic Coast. Gen. Lafayette and other officers of Washington's army once rested under its spreading shade while on the march, and a visit to the tree by Woodworth is said to have inspired the poem, "The Old Oaken Bucket." In front of Macedonia Church, in Columbia county, Georgia, is a quivering tree. Every limb, large and small, on the tree trembles as in fear, or as a suffering animal would quiver, and this occurs when not a breath of air is stirring.

The Scotch fir is a blessing to the country in which it grows. The poor man's hut is lighted by torches made of the branches, which burn most brilliantly owing to the resinous nature of the wood. In the barren parts of Sweden and Lapland the peasants select the oldest and least resinous of the branches, take out the inner bark, which they grind and mix with their scanty supply of meal, making it into cakes called bark-bread.

In the islands of the West Indies grows a tree resembling an apple tree in height and size, known as the calabash tree. It has wedge-shaped leaves, large, whitish, fleshy blossoms that grow on the trunk and big branches. The fruit is much like a common gourd, only a good deal stronger, and often measures 12 inches in diameter. The hard shell of this is cut into various shapes by the natives and is sometimes handsomely carved. It is made into drinking-cups, dishes, pails, and even pots, and can actually be used over the fire for boiling water. But the calabash pot gives out after a few trials over the fire, and is unfit for further service.

Probably the only trees which grow ready-made whistles are those found in the forests of Nubia. When this tree is swayed by the wind, strange sounds may be heard like the notes of a flute, a fife, or a penny whistle. The vocal tree was a wonder to all who heard the mysterious sounds, until explanation was given by a scientific traveller who investigated the matter. He found that at certain seasons of the year hordes of insects deposited their eggs on the young shoots and ends of branches. When the young insects emerged, small holes were left in the galls. The wind blowing through these openings caused the strange noise.

In New Zealand is a tree fatal to birds. The seed vessels give off a sticky fluid, and many a fly finds himself on the gummy stuff. Those flies attract small birds, and they too get so covered with the fluid that they are unable to fly. They are also attracted by the clusters of ripe fruit, which they intend to eat, but when once covered by this fatal gum they remain, not to eat, but to be eaten by other animals.

The most important article for illuminating purposes in Japan is the candle made from the fruit of a

tree which very much resembles the common sumac of this country, and is called "the vegetable wax tree." The berries are the size of a small pea, of a whitish colour, hanging in clusters, and contain the wax as a thick, white coating of the seed. The wax is obtained by the berries being crushed, strained and pressed in hemp-bags, or by boiling the bruised seeds and skimming the wax from the top. From experiments made, this tree can be readily grown in this country. It is highly ornamental as well as valuable for its production.

In a part of Africa not frequently visited by travellers, the discovery has been made of a tree which yields butter. Under no system of treatment can it be made to equal that churned from milk, but by salting it is somewhat similar. By heating with a solution of potash or soda it is easily converted into soap.

The "stinging tree" of Queensland is a luxurious shrub, pleasing to the eye, but dangerous to the touch. It grows from two or three inches to 10 or 15 feet in height, and sends forth a very disagreeable odor. Its effects are curious; it leaves no mark, but the pain is maddening, and for months afterward the part when touched is tender in rainy weather or when wet in washing.

A marvellous palm grows in the village of Pedur, in India. Some children plucked its fruit at five o'clock one afternoon and flocked early the next morning to gather more, but they found the branches now far above their heads. Observation showed that the tree had been elongating its position every morning and evening. It is 11 feet in height. One who has seen it writes: "At 5:30 the tree was almost lying toward the west. The foot of the tree was at an angle of five to seven degrees with the ground, and we were given to understand that it had already commenced to rise from four o'clock. A handkerchief which had been tied to one of the leaves, so that its other end just touched the ground, had risen six inches. At 8 p.m., the handkerchief was eighteen inches from the ground, and at 3 a.m., nine feet.*"

One of the greatest wonders of Madagascar is the "Traveller's Tree." Its stem resembles that of a plantain; but it sends out its two wing-like leaves (which resemble a large expanded fan) on opposite sides of the stalk. In an aged tree the lowest of these leaves will be from 20 to 40 feet from the ground. The fruit grows in large bunches, with three or four such bunches to a tree. The leaves are used for roof thatching, and the leaf stalks twisted together serve for the walls of the islanders' huts. The most remarkable property of this, and the one which gives its name "traveller's tree," is its leaf stalks, which, even in the driest seasons, always contain water; and the wayfarer, if he be thirsty, has only to pierce the thick base of a stalk to obtain fully a quart of pure and refreshing liquid.

Newton, N. C., has a curiosity that beats by a large majority the rain tree which gained such notoriety in Charlotte in 1886. It is a smoking tree, and baffles all efforts at explanation. It is a white mulberry tree, was brought from Illinois a year or two ago, and is now about 12 feet high, with a bushy top and many lateral branches. Puffs of smoke, identical in appearance to cigarette smoke, are seen starting every now and then from all over the tree; sometimes from the leaves, sometimes from the bloom, sometimes from the bark of the limbs or trunk. The puffs are at irregular intervals; sometimes two or three at once from various parts of the tree, and sometimes they are several seconds or a half minute apart. They just come haphazard from any part of the tree, and as they ascend in the air, look exactly like the smoke from a cigarette.

Professor Scholwisch, the well-known naturalist of Bavaria, while travelling with the Stanley expedition in the heart of Africa, noticed a plant with a peculiar steel-colored foliage. It was growing like other plants from the soil, but on examination was found to be practically composed of iron. The leaves, although very thin, were bent with great difficulty,

* We confess to scepticism.—Ed. T. A.

and in order to secure one, it was found necessary to separate it from the branch with a file. On further examination and experiment, it was found that the plant, or tree, eagerly devoured any metal its roots might come in contact with, and changed its color to the color of the metal last absorbed. [? Ed. T. A.]

Major Quincy A. Steele, who has been with an engineering corps surveying railroads in Central America for the last two years, gives an account of some very curious trees he met with there. Among the funniest are the electric-light tree, which gives milk, and the dough-producing tree. The electric-light tree gives a light so strong that you can read or write by it by night; this tree is not a large one but very conspicuous, and scores of them may be seen over the country, like beacon lights set in the hills.

The milk tree has a big tough skin that can be used for half-soleing shoes. To milk the tree, a hole is bored in the trunk; then it lets down sap as white and as sweet as any even milked from a cow.

The bread from the *bread-tree* is not exactly bread when picked, but it is a nice stiff dough inclosed in a nutshell about the size of a goose egg. The nut is cracked, the dough taken out and kneaded a little, then is ready for baking. By thinning it down with a little milk from the milk tree, it makes excellent pancakes.

In behalf of those who are interested in trees, I have collected the foregoing from what appears to be reliable literature, and without doubt truthfully describes these forest wonders.—*Cal. Rural Press.*

THE CULTIVATION OF THE PINE-APPLE.

(*Ananas sativa*, Sch.)

The pine-apple is a native of tropical America, but having become naturalised and growing in great abundance in the warmer parts of Asia and Africa, some authors have written of the plant as being indigenous to those countries. Dr. Lindley, in treating of Bromeliaceous plants, affirms, however, that it is a native of the continent and islands of America. The pine-apple is exceedingly tenacious of life, and, owing to this circumstance, was probably one of the first tropical fruits transplanted successfully from its original home to other warm countries. It has been grown successfully for very many years in most of the warmer parts of the earth. The plant has already proved itself to be well adapted to the Australian climate. It frequently ripens its fruit in sheltered positions in the vicinity of Sydney; but to grow the plants as a commercial product it requires a warmer part of the Colony than the latitude of Sydney. From the Clarence to the Tweed Rivers, however, there are numerous eligible sites for pine-apple plantations, which would, under careful management, return handsome profits on the outlay, not only by shipping the fruit to market but also by growing it for canning purposes. A cannery need not be an expensive affair, and one might very well be started by farmers on the co-operative principle in some central position on the Clarence, Richmond, or Tweed Rivers. If the cannery were supplied with plenty of fruit during the season (and this could be easily done), I can safely say that, with good management, it would turn out to be a commercial success. About twelve months ago, I visited a large cannery in Melbourne, where pine-apples were being imported in great numbers from Queensland for canning purposes. If it paid a Melbourne firm to import pine-apples from Queensland and can them, how much more would it pay New South Welshmen to grow them and can them on the spot? Besides the ordinary profits made on canning the fruits, the amount paid in freight and customs duties by the Melbourne canners could be added to the profits, which would be considerable if the industry were properly started here. The canning process is withal so simple that it does not require a great outlay in machinery or a great amount of skilled labour. It is necessary for canning that the pine-apples should be ripe, and as near the same size round as it is possible to get them; so that when they are cut, the slices will fit evenly in the cans;

this will save syrup, and, besides, the preserves will present a better appearance when opened. The operation of peeling and slicing is done on tables by either women or boys. The pine-apples are cut across into slices about a quarter of an inch thick; these are carefully laid in the cans until they are a little over three parts full; a thick syrup is then poured out of a ladle into the cans, but they are not quite filled. The tops of the cans are then soldered on, and the cans are then put into an iron framework holding about fifty, and are lowered with a block and tackle into vats containing boiling water. After boiling for several minutes, the cans are taken out and perforated at the top to allow the steam to escape; then they are hermetically sealed and put somewhere to cool. When the cans are labelled they are ready to be placed on the market.

Varieties.—There are numerous varieties of pine-apples. I once had twenty-two under cultivation; but for all practical purposes the number could be reduced to three or four. I subjoin a list with description of those that I consider best for general cultivation.

Black Jamaica.—Leaves small, narrow, dark green; spines small and thinly set; fruit oval, somewhat pyramidal, dark brownish yellow; pips middle-sized, prominent, flattened in the centre; flesh firm, pale yellow, rich, juicy, and highly flavoured. Its weight is generally from 4 lb. to 5 lb.

Charlotte Rothschild.—Leaves broad, with strong spines; dark green above and merely underneath; fruit large, cylindrical, or slightly barrel-shaped; pips large, flat, golden yellow; flesh yellow, and very juicy. Its weight is generally from 7 lb. to 10 lb.

Queen.—Leaves very short, broad, of a bluish green, very mealy; spines strong, set widely apart; fruit cylindrical, or a rich deep yellow; pips middle-sized, prominent; flesh pale yellow, juicy, sweet, rich, and excellent. Its weight is generally from 3 lb. to 8 lb. This variety is undoubtedly the best to cultivate for a summer crop; it is very hardy and matures early.

Smooth-leaved Cayenne.—Leaves long and smooth, or with very few spines; fruit very large, pyramidal, dark orange yellow; pips large, flat; flesh pale yellow, rich and highly flavoured. A very handsome fruit weighing from 6 lb. to 9 lb. It is essentially an autumn and winter fruiting variety. This variety is largely grown in the Azores for the purpose of supplying the English market during the winter and early spring months.

The site of a pine-apple plantation should be fully exposed to the sun, but sheltered against prevailing winds—especially the southerly and westerly ones. The land should be well broken up with a strong plough, drawn by bullocks, to a depth of at least 15 inches, exposed to the influence of sun and air for sometime previous to the planting taking place, and be aerified occasionally. The soil best suited to the growth of the pine-apple is one that is fairly rich in humus (which can be easily found in the north-eastern portion of this Colony), and affords a free passage of water through it, with a well-drained subsoil; nothing harms the pine-apple so much as stagnant moisture.

The Propagation of the Pine-apple.—This is effected by seeds, crowns, cuttings of the stem, and suckers. The latter, however, is the best and most expeditious way, and the one generally adopted. Suckers not only fruit much quicker than those propagated by other means, but also produce the finest fruit. Therefore, I shall only treat of that mode of propagation. Suckers will form at the base of the plant when it is in fruit, and, after the latter is ripe and cut off, they will grow quickly. The best time of the year to take them from the parent plant is in March, or at the latter end of September. March is the best month, however, for the young plants will have a better opportunity of making considerable root action before the hot weather sets in, and, consequently, they will come to a fruiting state much earlier than those that are not planted till spring. The suckers should be carefully removed from the parent plant, by taking hold close to their base and moving them from side to side, besides twisting a little at the same time. Their bases should be pared with a sharp knife, and a few, only a very few, of the lower leaves taken off. They will now be ready for planting.

Planting.—The pine-apples should be planted in rows 3 feet apart, and 3 feet apart in the rows; at this distance an acre will take 4,840 plants. When laying out the land for planting, 9-foot stakes should be fixed in an upright position, about 50 feet or more apart, to mark the lines where the pines are to be planted. This will ensure the rows being straight; this not only facilitates working the land, but the fruit, when ripe, is easier to gather. When everything is ready for planting, lines should be strung between each stake, then with a spade or hoe take out just sufficient soil to make a mark close to and parallel to the line. A straight line might be made, however, with the aid of stakes and a very light plough, yoked on to a pair of horses driven by a good ploughman. After the line is made, a man should then come along with armsful of young plants, and lay them at 3 feet distances; another man should follow and plant them. In planting, see that the soil is made considerably firm about the young plants; neglect in this particular will prevent them making roots as quickly as they otherwise would, which, of course, would also retard their growth considerably. After the planting is done, the stakes may be taken out. The only attention that the plants will require, until the fruit is ready for cutting, is to keep them free from weeds, and the soil kept loose between the rows by means of the hoe.

Age of the Plant when the first crop of fruit is ready for gathering.—This may safely be reckoned to be at from 18 to 22 months, according to the size and strength of the suckers when planted. The first crop will be quite 4,000 marketable fruits to the acre; but considerably more would be procured from the second and third year's crops, because the suckers that have formed round the parent plant would bear fruit. If we calculate the return per acre at 4,000 pines, these would, at 3d. each (both very low estimates), return a handsome profit of £50. The working expenses to be set against this sum are not heavy, and our farmers are cultivating crops at the present time at far less profit. If the fruit is required for market, and it has to travel some distance, it should be cut before it is quite ripe; but if it is required for canning purposes, and the cannery is not far distant, the fruit may be left on the plant until it is nearly ripe. A convenient contrivance for bringing the fruit out of the rows is a light hand-cart, made of lattice-work, and set on two wheels with broad tires. Its size should be such that it will go between the rows of plants. After a plantation has been in bearing for four or five years, the plants will cease to bear fine crops of fruit, and it will hardly pay to keep them on the ground. The next best thing to be done is to break up the plantation, save the best of the suckers for planting a new one, and put the land under another kind of crop, or give it a rest for a time, and, if suitably situated, plant it again with pine-apples.

Fertilisers.—If the land is not very rich at the time when the pine-apples were planted, some manure should be applied to after the first crop of fruit is taken from the plants. I have found nothing better than bono dust or super-phosphate of lime applied in moderate quantities, and with discretion. For instance, the manure should not be applied when the fruit is forming on the plant, neither should it be applied when the fruit is near ripening.

Insect Pests.—The only insects which I have seen preying upon the pine-apple are the Mealy Bug and the Scale; but neither of these pests are very troublesome to the plant when it is under good cultivation. If these insects should, however, establish themselves on the plants, spray them with a strong solution of tobacco water, at any time except when the plant is in bloom and the fruit is near ripening.

Pine-apple Fibre.—Besides the splendid fruit that this plant produces, it has another important economic product in the capital fibre that can be obtained from its leaves. But it would not pay in Australia to cultivate the plant for its fibre alone. However, it would be a very good thing to take in hand as an auxiliary product, for the preparation of the fibre for market; since it is claimed that machinery can be brought into use to clean and turn it into a marketable commodity. We could never hope to separate

the fibre from the spiny leaves of the pine-apple by hand, as it is done by the Chinese, and then compete with them in the market with the produce. Neither is it desirable that we should; for not only is the process a tedious one; but the spiny leaves will, on coming in contact with the flesh, often cause sores. Leaves that are wanted for making fibre from should be taken from the plants soon after the fruit has been gathered. Cut the leaves as low down as possible; but, at the same time, care must be taken that the suckers are not interfered with, because it is from these that the future crops of fruit are expected. Pine-apple fibre is remarkably strong—as has been proved from some tests conducted at the arsenal, Fort William, with a rope made of this fibre 3½ inches in circumference. The Government proof was, that a rope of this size should bear a weight of 22 cwt.; but it bore no less than 15 cwt. more, that is, it broke with a weight of 57 cwt. The following extract from a Singapore paper describes the process that the Chinese follow in preparing the pina fibre for market:—"The process of extracting and bleaching the fibre is exceedingly simple. The first step is to remove the fleshy or succulent sides of the leaf. A Chinese, astride of a narrow stool, extends on it in front of him a pine-apple leaf, one end of which is kept firm by being placed beneath a small bundle of cloth on which he sits. He then, with a kind of two-handled plane made of bamboo, removes the succulent matter. Another man receives the leaves as they are planed, and with his thumb-nail loosens and gathers the fibre about the middle of the leaf; this enables him by one effort to detach the whole of them from the outer skin. The fibres are next steeped in water for some time, after which they are washed in order to free them from the matter that still adheres and binds them together. They are now laid out to dry and bleach on rude frames of split bamboo. The processes of steeping, washing, and exposing to the sun are repeated for some days, until the fibres are considered properly bleached. Without further preparation, they are sent into town, for exportation to China. Nearly all the islands near Singapore are more or less planted with pine-apples, which, at a rough estimate, cover an estimate of 2,000 acres. The enormous quantity of leaves that are annually allowed to rot on the ground would supply fibre for a large manufactory of valuable pina cloth. The fibres should be cleaned on the spot."—*Agricultural Gazette.*

TEA AND COFFEE SUBSTITUTES.

LAURINEÆ.

67. *Sassafras officinale*, Nocs.—A large tree of North America, well-known for its aromatic bark, which is used in medicine as a tonic. A decoction of the root is used in America under the name of Sassafras tea, as a warm, mucilaginous, aromatic drink, especially in fevers, bronchitis, catarrh, &c. In military encampments in America, Sassafras tea is said to have been at one time in almost daily use both by officers and men as a favourite substitute for green tea. It has a reputation as a blood purifier, and was many years ago used in this country for the same purpose, and as a warm aromatic drink, being sold in the early morning at the temporary coffee-stalls which then existed at the corners of the streets in the southern and eastern parts of London.

PROTEACEÆ.

68. *Brabejum stellatum*, R. Br.—A shrub 8 to 10 feet high, growing in thickets and woody ravines on the east side of the Table Mountain, and in many other localities at the Cape of Good Hope. It is known as the wild Almond, in consequence of the fruit and seed being Almond-shaped, the latter, after being soaked for some days in water, are eaten by the natives who also roast and grind them and use them as coffee.

SANTALACEÆ.

62. *Osyris arborea*, Wall.—This plant is described as being very common around Simla. In Kumaon it is known as Bakardharra, bakaria; in Belgaum, as Popli;

and in Nepal, as Jhuri. The use of the leaves as a substitute for tea in India is said to have been noticed as far back as 1821. Dr. Watt says the leaves are used, here and there throughout the Himalayas, from Almora to Sikkin, in place of tea. When specially prepared they have a strong tea-like smell, but the infusion has powerful emetic properties which require long usage to overcome. Dr. Royle suggested that experiments should be made in the cultivation of the plant in order to discover if this emetic property could be removed by careful cultivation. The discovery of tea proper in Assam, and the greatly extended cultivation of that plant, have left the matter of Osyris tea in the position in which it was at the beginning of the present century, when it first attracted the attention of the public. There is a good sample of this tea in the Kew Museum.

URTICACEÆ.

76. *Ulmus campestris*, Sm.—The common Elm, Johnson, in his *Useful Plants of Great Britain*, a book published many years ago by Hardwick, without date, says:—"Some years ago an immense quantity of dried Elm leaves were used for adulterating tea, and for manufacturing a substitute for it. They are astringent, but contain a considerable quantity of mucilaginous matter."

77. *Mississia corymbulosa*, Wedd.—This plant, which is now sunk under the genus *Leucosyke*, is a straggling shrub from 6 to 8 feet high, growing in Fiji, where it is known as Matadra. Seemann, in his *Flora Vitiensis*, says:—"Some of the white residents in Viti have drunk a decoction of the leaves without perceiving it to be different from Chinese tea. The natives do not seem to use the plant in this way."

78. *Pilea argentea*, DC.—The leaves of this plant are stated in Rosenthal's *Synopsis Plantarum Diaphoricarum*, to be used in Greece as a substitute for tea, though nothing is said about the extent of its consumption or of its peculiar properties.

MYRICACEÆ.

79. *Myrica asplenifolia*, Endl.—An American plant native of the mountainous parts of N. Carolina, and extending northwards. It is known as Fern Bush or Sweet Fern, and from the plant a pleasant aromatic astringent drink is made, and generally used in the summer complaints of children. The dried leaves are said to make an excellent tea. The plant is frequently known as *Comptonia asplenifolia*. There is a good sample in the Kew Museum.

CUPULIFERÆ.

80. *Betula alba*, L.—The white Birch. Among the uses to which this valuable tree has been put, is the adaptation of the dried leaves for tea, a use to which it is said they are commonly put in Finland.

ORCHIDÆÆ.

81. *Aceranthus fragrans*, Rehb.—This Orchid is perhaps better known as *Angrocum fragrans*, Thouars. A native of Mauritius and Bourbon, where it is known as Faham. It was first brought to notice as a tea in this country in 1866, having been brought from Paris, where it had been sold for some time. The leaves are simply dried and packed in small boxes, and from the label it would seem not to have been introduced for the purpose of supplanting Chinese tea, but to afford an opportunity of choosing between two beverages equally beneficial and useful.

The following notes are from an account of Faham tea which I gave in the *Gardeners' Chronicle* for April 7, 1866, p. 315. It is a translation of a circular which accompanies each packet:—"Faham is not a new production. From time immemorial, the natives of the Islands of Reunion and Mauritius, situated as it were at the very gates of China, have preferred it to tea; every traveller has partaken of their preference. One of our most illustrious writers, Georges Sand, eulogises it in the midst of the fine description which she gives of the Isle of Bourbon, a eulogy which cannot be suspected of puffery, inasmuch as it was written thirty years before the introduction of Faham into France was thought of. Every work on botany of any importance similarly places it in the foremost

rank of the beneficial productions of this favoured clime. The difficulties experienced in the gathering and manufacture of Faham on a large scale, and consequently the almost impossibility of procuring a sufficient quantity to recompense the labour of obtaining it for consumption, and also its very high price, have alone prevented until now this valuable article of diet from being imported into France. After many fruitless attempts, these obstacles have been overcome.

"Faham tea possesses a taste differing greatly from that of true tea, and is preferred by the majority of persons who have tasted it. It can be used as a substitute for tea on all occasions, as it combines its tonic and digestive qualities, free from the sleepless effect. It possesses an aroma of great delicacy, capable of being rendered more or less pungent, according to the quantity used, and it gives forth a most agreeable perfume. After being drunk, it leaves a lasting fragrance in the mouth, and in a closed room the odour of it can be recognised long after. This beverage has the further advantage over tea, which requires to be drunk at the time of making, that it can be reserved for a future occasion, if required, and may be either taken cold or made hot again. Milk or spirits in small quantities, especially rum, serve to develop its aroma, and, lending it additional delicacy or greater strength, render it a delicious drink. Lastly, this valuable plant is made use of to flavour custards and ices, to which it communicates its delicate fragrance.

"To be taken as a warm beverage, the leaves and stalks should be placed in cold water in about the proportion of 1 gramme to a tea-cup, more or less, as the consumer may desire it of a greater or lesser degree of strength. The water should be immediately made to boil for about 10 minutes in the tea-kettle or other closed vessel. It should then be emptied into the tea-pot or tea-cups, and sweetened accordingly."

In the so-called tea, the leaves are simply dried without being curled or roasted, and in their dried state, as well as in infusion, they emit a strong fragrance, resembling that of the Tonquin Bean. There is a good sample of this tea in the Kew Museum.

LILIACEÆ.

82. *Smilax glycyphylla*, Smith.—A glabrous climbing plant, with the stems and branches more or less armed with scattered prickles. It is found in N. Australia, Victoria, New South Wales, and Queensland. A decoction made from the leaves has a sweet taste, and is used in Australia under the name of Sweet Tea or Botany Bay Tea. It would seem, however, to be used more as a medicine than a tea proper, for it is stated to have similar properties to Jamaica Sarsaparilla, which is a nearly allied plant.

PALMACEÆ.

83. *Phoenix dactylifera*, L.—Date Palm. Under the name of Date Coffee, the hard, horny seeds of this well-known Palm were roasted and ground, and largely advertised a few years ago as a substitute for true coffee. A company was formed for the exclusive manufacture and sale of this article, which is now seldom or never heard of.

GRAMINEÆ.

84. *Andropogon citratus*, DC. (Lemon-grass).—This scented-leaved grass occurs only in a cultivated state, and very rarely flowers. It is cultivated in Ceylon and Singapore for the sake of the fragrant oil which is distilled from the leaves, and used in perfumery. In the fresh state these leaves are said to be sometimes used as a substitute for tea, under the name of Citroncello tea; a warm infusion made from them is likewise stated to be a valuable medicine in febrile affections.

FILICES.

85. *Aspidium fragrans*.—The fronds of this Fern, which have a scent similar to that of the Raspberry, are much esteemed in the north of Asia for their antiscorbic properties, and are used as tea by the Mongols.

86. *Adiantum caudatum*, L.—A widely-spread Fern throughout the Tropics of the Old World, is used as tea in Rouman, under the name of Capillaire.

81. *Pellea flexuosa*, Link.—In Fournier's *Mexicanum Plantarum Enumeratio*, it is stated that the fronds are used as tea in Mexico.—JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle*.

(To be continued.)

THE FOREST PRODUCTS OF MADAGASCAR.

Among the forest products of Madagascar, caoutchouc is found all over the island, but, says the Chancellor of the French Residency at Antananarivo, in those places which are easy of access, it is beginning to be scarce, and the prices have considerably increased, particularly on the markets of the east coast. On the west coast, where business is less brisk, and where the population is sparser, it is still low priced and abundant. The diminution in the supply is to be attributed, among other causes, to the negligence and indolence of the natives, who, regardless of the future, cut the trees at the foot, in order to more easily arrive at the milk. It is prepared in different ways, and, in those places where there are Europeans, it is possible to obtain it treated with acid, but in many places, either because the cost of sulphuric acid is too great or on account of the fact that numerous accidents in the manipulation of this substance has rendered it unpopular, tea, salt, absinthe, citric acid, or an extract of tamarinds are substituted. The prices vary according to the locality, and also according to the system adopted and the care taken in its preparation. Caoutchouc enters, to a very great extent, into the exports of the country, and, in order to encourage this industry, the Government ought, in M. Anthonard's opinion, to look carefully after the preservation of the forests, endeavour to prevent fires, and to induce the natives to abandon their habit of cutting down the trees bodily. In these circumstances, Madagascar caoutchouc might realise high prices upon European markets, and successfully compete with the Para product. Gum copal is exported in considerable quantities from the ports on the east coast of Madagascar, and, up to the present, it is only on this coast that the product has been obtained, although there appears to be no reason why the west coast should not furnish its quota. A far more important business might, it is said, be done in this article if greater care were only taken by the natives in its preparation, and if it could be cleansed of its impurities; the quality would then be equal to the Netherlands East Indies. Similar reasons to those which have brought about a reduction in the prices of caoutchouc, have caused a diminution in the volume of business carried on in honey and wax. This product, gathered without any care, and full of foreign substances which have the effect of deprecating it, is nevertheless quoted on the European markets at the same rates as the Senegal product. The natives, to obtain a few pounds of honey or wax, frequently destroy an entire hive, and consequently the swarms of bees are becoming much scarcer. It will be necessary to introduce considerable improvements in the method of gathering this product in Madagascar before any rise in prices can reasonably be hoped for. There is a considerable export of raffia fibre from the ports of Tamatavo, Vatamandry, and Majunga. The principal centres of production are on the east coast, between Tanatave and Vatamandry, and in the interior, towards the west of the route, from Antananarivo to Majunga. The exports of this article from the latter district, which, some few years ago, were almost nil, have of recent years largely increased. The principal markets in Europe for raffia fibre are London, Haver, and Marseilles. The fibre is largely used by wine growers in tying up their vines, and it is also employed for many other purposes. Attempts have been made to weave it. Ebony, at one time, was exported in considerable quantities from the north-east coast, but at the present day the trade appears to be entirely confined to the west coast. The forests of Madagascar abound with timber, eminently adapted for building purposes, furniture and cabinet making.—*Journal of the Society of Arts*.

THE TEAK TRADE OF BURMA.—With regard to the teak trade of Burma during 1890-91, Rangoon again takes the lead. There were exported from Rangoon during the year 110,555 tons and from Moulmein 64,167 tons, as compared with 163,459 and 80,765 respectively the preceding year.—*Pioneer*, Sept. 15.

THE PLANTERS in British North Borneo are loud in their praise of their Governor, who has just arranged, among other things, for the importation of coolie labour to that Colony. The Governor's strenuous and unremitting efforts to secure this boon for the planting community around Sandakan have now been crowned with success, and His Excellency's thoughtful policy is much appreciated.—*Colonies and India*.

DR. JOHN DONGALL, of St Mungo's College, Glasgow, has a letter in a recent issue of the *Glasgow Herald* on the banana, in which he quotes from Stanley's "In Darkest Africa" to show that "for infants, persons of delicate digestion, dyspeptics, and those suffering from temporary derangements of the stomach, the flour, properly prepared, would be of universal demand." During Stanley's two attacks of gastritis a slight gruel of this flour, mixed with milk, was the only material that could be digested. It is odd, also, as pointed out in Stanley's book, that in most Banana lands—Cuba, Brazil, West Indies—the valuable properties of this fruit as an easily digested and nourishing food have been much overlooked. Dr. Dougall has made some experiments in making banana flour. He concludes that it should be made from the ripe fruit at its place of production. In trying to make it from bananas purchased in Glasgow, he obtained on drying the pulp a tough sweet mass like toasted figs, an appearance probably due to the conversion of starch into sugar. Bananas contain only about fifty per cent. of pulp, and of this about seventy-five per cent. is water. They would yield, therefore, only one-eighth part of flour.—*Garden and Forest*.

In an article called the "Evolution of Patent Medicine," published in the *Popular Science Monthly* for May, Mr. Lee J. Vance traces that belief in the efficacy of such nostrums back to those ancient times when no distinction was drawn between the physician and the magician, and when all remedies were looked upon as charms—a condition which prevails, of course, among savage and half-civilized tribes in our own times. The names of plants, Mr. Vance explains, shows how general was the belief in their inexplicable virtues. "Some plants have animal prefixes, as, Dog-elder, Dog-rose, Cat's-tail, Cow-bane, etc. Other plants derive their name from religious sources. Thus they are associated with the Virgin Mary, Saint John the Baptist, Saint James. Likewise the latter-day Saint have particular plants dedicated to their memory. Most of the plants with mystic names were supposed to have magical virtues, and so they were largely used in folk-medicine. The weird associations clustering around many roots and herbs were enough to invest them with great repute," and in folk-medicine even at the present day, "herbs are used not so much for their inherent medical properties as for their reputed magical virtues. . . . Another stage in the evolution of medieval medicine is typified in the therapeutics of medieval mystics and alchemists. The great plant in their pharmacopœia was the Mandrake. Why? Simply because the roots of this plant were shaped like the human body. . . . The magical element in patent medicines actually won scientific repute in the 'doctrine of signatures'—a doctrine which held that plants and minerals, by their external character, indicated the particular disease for which Nature had intended them as remedies. Thus the Ephrasin or Eyebright, was good for the eyes; the Wood-sorrel, being shaped like a heart, for the heart; the Liverwort for the liver, and so on. Pettigrew, in his history of medical superstition, says that this fanciful and magical notion 'led to serious errors in practice' and often to fatal results. Observe that at this stage of its evolution patent medicine is herb medicine, and so it remained for a long time. The materials of the healing art were all vegetable. The patent-medicine man was a dealer in herbs."—*Garden and Forest*.

THE QUALITY OF OUR TEAS, AND SUGGESTIONS IN THE DIRECTION OF IMPROVEMENT.
INDIA TEA PRODUCTION AND EXPORT.

We continue to receive complaints as to the quality of our teas which have of late reached the London market, and it is asserted that their inferiority has been the main cause of the low prices of late obtained for them. The complaints have been of so strong a character, and have been received from quarters occupying so high a position in the trade, that it seems to be most desirable that attention should be forcibly directed to the matter. It is all very well, exclaim our home friends and mentors, to say that at certain seasons of the year the leaf produced in Ceylon is of a quality inferior to the general average, and that it is from this cause that the complaining in question has arisen. But the point should then be considered whether it may not be possible to obviate this, for it must manifestly be of great harm to the reputation of Ceylon teas that whole shipments should be received in London of an undesirable quality. Our London correspondent has informed us that it was within his knowledge that very recently a large purchaser returned to the broker fully one-half of the quantity bought by him as being far below the quality of the samples upon which he was induced to buy. Herein we see the element of uncertainty introduced independently of the inferior quality of the break dealt with. If buyers cannot rely upon their purchases being up to sample at least, however poor that sample may be, further great harm must result. It may be said, perhaps, that the selection of the samples rests with the broker or his agents, but it must be exceedingly difficult to discriminate in the case of a larger break which is of uneven quality. The blame, therefore, in such a case cannot be said to be wholly due to the agent at home, and it is manifest that more care should be exercised in keeping distinct and separate portions of shipments which may be below the standard of the tea generally. But quite apart from this view of the matter is the question of seasonal general inferiority upon which we first touched. Some time ago it was determined upon, as the result to the prices obtained in London, that it would pay our planters better to produce teas of a description below the standard of the highest class. Against this conclusion we could find nothing to urge, the difference between the prices obtained for medium and higher class teas being not sufficient to render it worth the while of the planter to incur the extra cost involved in the production of the higher descriptions. But what has now to be considered, in view of the recent depression in prices obtained for our teas in London, is whether at the season which is known to be that at which our leaf degenerates, it would not be wiser for our planters to pluck it at earlier stages than is usual and so maintain a standard at least level with that of the teas shipped during seasons more favourable to the quality of the leaf. We cannot see that there could be any insuperable difficulty in doing this. It is true that shipments at such times would have been more costly to the planter than the average of the production of the year taken all round; but two great advantages would be gained which must go far, we should say, to compensate for the extra outlay. In the first place we should not annually have to look forward to the serious diminution in prices obtained which, under present conditions, we seem to be fated to expect; and in the second place, the reputation of our teas would be steadily maintained, and all

concerned with the tea trade in London urge that this is a most important factor in regard to the tea trade generally. If plucking the flush at an earlier stage of development than is usual, is objected to as hard on the bushes, then every effort should be made to have space and appliances for good withering available. Mr. Jackson claims for his Britannia drier that it is a most effective witherer. Some extra expenditure in this direction would be well applied. For we can realize that the consumer who, we will say, is just making trial of our tea and has had every reason to be satisfied with his first two or three trials of it, would be very likely to discontinue the use of Ceylon tea if he found that his next purchases were of quite a different quality and flavour to those of his first essay. It may be, as we have already indicated, that practical planters may say that there would be difficulties in carrying out what we suggest, namely finer plucking during what may be termed the off-season of our tea bushes. But if there be such difficulties, it is, for the reasons that we have pointed out, only the more necessary that measures should be sought for and adopted to overcome them, or to improve watery leaf to the utmost my extra care in manufacture. The matter as it stands is an exceedingly serious one, and one that needs active measures to redress if the reputation we have earned is not to suffer materially. We hear much complaint of the insufficiency of the prices of late obtained to give a fair return for the cost the grower has incurred. But, we would ask, is the latter not himself largely responsible for this very disagreeable fact? We feel quite sure that unless a uniformity of quality—not necessarily in the highest classes of teas—can be maintained all the year round, much of the ground that we have gained will be lost. We ought never to hear of Ceylon teas being spoken of as "rubbish," and yet that is the unfortunate term, we are assured, applied to many of the shipments which have recently been sold in Mincing Lane. We do not profess to have proposed an infallible remedy against the evil, but what we have written seems to us likely to afford some hints in that direction.

After all is said and done, however, it is the Ceylon tea which is finding chief favour in Britain and her Australian colonies, in the face of all the clamour about occasional descents in certain conditions of weather, from the high standard of quality to which consumers had become accustomed. The deliveries of Indian as well as China teas in Britain showed at latest date a comparative falling off, while the whole of the increase was in Ceylon. For the three months from June 1st to Aug. 31st the proportionate deliveries were:—

Indian	21,000,000 lb.
China	19,532,000 "
Ceylon	16,000,000 "

Deliveries of Ceylon at the same rate for the twelve months would total 64,000,000; and even if this figure were not increased, deliveries would be well up to our rapidly increasing production. Then, we may take it for granted that Australia will take 5,000,000 lb. at least and other countries 1,000,000 more. We quoted, when it appeared, Mr. O'Connor's general review of the Indian tea trade; and now the more detailed report has reached us, from which we quote significant figures and deductions. Reviewing the export trade of 1890, the Assistant Secretary of the Indian Commercial and Statistical Department wrote regarding Indian tea:—

"The exports amounted to 107,014,993 lb., which was but little more than 3 per cent in excess of the quantity exported in the previous year. This is a slower rate of progress than has been made in

previous years, but possibly the present year may see a further advance.

The exports of the last eight years are given below:—

	(000's omitted.)	lb.	R.
1883-84	...	59,912	4,083,880
1884-85	...	61,162	4,044,759
1885-86	...	68,784	4,306,133
1886-87	...	78,703	4,727,992
1887-88	...	87,511	5,174,440
1888-89	...	97,011	5,267,315
1889-90	...	103,760	5,277,650
1890-91	...	107,015	5,219,233

The heavy fall in price which marked the year 1889-90 was succeeded by a further fall last year for the higher qualities of tea, the fall occurring during the months when exchange was raising. The average prices realized at the auction sales in Calcutta during the last three years were as follows, in annas and pie per pound:—

	1888-89.	1889-90.	1890-91.
Orange (and broken orange) Pekoo	... 12-4	11-8	11-2½
Broku Pekoo	... 10-3	9-9	8-10½
Pekoo	... 8-1	7-5	7-2
Pekoo Souchong	... 6-3	5-7	5-8½
Broken ditto	... 5-10	5-0	5-3½
Pekoo Fannings	... 6-6	5-7	5-10
Other low classes	... 4-11	4-8	5-2

The London market continues to absorb the bulk of the exports, but there is a noteworthy increase in the exports to Australia which have more than doubled in four years. An export of five million pounds is not much after ten years of exertion to secure a market in colonies which consume tea very largely, but it may be taken as an indication that the merits of Indian tea are now understood there and that the Australians will no longer be content to drink China tea merely because it is cheap.

The exports are as follows, in pounds (000's omitted):—

	1887-88.	1888-89.	1889-90.	1890-91.
United Kingdom	84,182	93,222	98,731	100,209
Australia	2,472	2,880	3,419	5,119
Persian Gulf	324	467	1,200	1,311
United States...	54	155	103	79
Canada	...	14	85	61
China	...	6	19	33

While the imports of Indian tea into England continue to increase, those of Chinese tea continue to diminish, but while China is being gradually but surely thrust out of the English market, another and perhaps a more formidable competitor has stepped in. The advance made by Ceylon tea in recent years is little short of marvellous. It is interesting to note how completely the position in England of Indian and Ceylon teas with respect to China tea has been reversed. Seven years ago the imports of China tea were more than double the imports of Indian and Ceylon teas. At the end of seven years we find the imports of China tea to be about half the imports from India and Ceylon. The following are the imports from India, Ceylon, and China into England in the last seven years (quantity stated in lb, 000's omitted):—

	From India	From Ceylon	From China
1884	... 63,208	... 2,211	... 143,771
1885	... 64,382	... 4,242	... 139,673
1886	... 73,467	... 7,144	... 145,398
1887	... 84,645	... 13,062	... 119,799
1888	... 89,874	... 22,509	... 105,735
1889	... 95,384	... 32,673	... 88,558
1890	... 101,771	... 42,491	... 73,743

Thus India and Ceylon furnished last year two-thirds of the imports, India's share being about 45 per cent while China furnished only one-third. Twenty years ago China's share was as much as 83 per cent; but twenty years ago Ceylon sent no tea to England and it had only one per cent of the imports as lately as 1884. It is said, with reference to the remarks in paragraph 21 of this review, that the quality of Ceylon tea is deteriorating and, with a poor soil, will continue to

deteriorate; and that therefore the Indian planter has nothing to apprehend from his Ceylon competitor. It is undesirable to be over confident in commercial competition, and it may be expedient to reflect that the Ceylon planter, who has already made such a success of his business, is hardly likely to make the mistake which is destroying the Chinese tea industry. There is also no sufficient evidence as yet that quality is deteriorating: on the contrary, Messrs. Steuning and Inskip, in their review of the tea trade of 1890, say in regard to Ceylon tea: "Quality has shewn a distinct improvement on that of last year, the fermentation having been better than hitherto. Flavoury teas have commanded very satisfactory prices."

The increase in the exports of Indian tea (and all but a fractional portion is exported) was in round numbers, for the eight years ending June 1891, from 60 millions of pounds to 107 millions, a good rate of increase, but entirely distanced by the Ceylon product, which showed an export in 1883 of only 1,641,810 lb.; while the figures for 1890 were 46,901,554 lb. Of course our ratio of increase will now diminish, although we are going ahead at a rate which demands every possible effort to keep up quality and open new markets. In the Customs value of the Indian tea exported, the increase in the eight years has been little more than a million of 10 rupee pounds,—Rs5,219,000 in 1890-91 against Rs4,083,000 in 1883-84. The downward course of prices in the past three years has been at least as severely felt by Indian producers as by our own planters. All wise economies must be exercised by the latter, and we have emphasised the word "wise," because we believe that a wise liberality in regard to the best manufacturing appliances and also in the application in many cases of the best fertilizers to our soil, will be our best policy, even in the light of economy. Of course our friends across the water take the most unfavourable view of our soil; and it cannot be denied that in cases where old coffee plantations were converted into tea estates, the soil does want fortifying, and so with some of our older estates opened in forest. But we are persuaded that a forcing and damp climate was, more than defective soil, the cause of the deterioration in quality of our tea exported early in this year. The meteorological conditions favoured quantity at the expense of quality.—Of Indian tea sent to the United States direct, the account is as "beggarly" as in the case of the Ceylon product, the quantity being only 79,000 lb., against over five millions to Australia. We do not know what quantity of Indian and Ceylon tea reaches the United States from Britain, but it cannot be much, in view of unfavourable fiscal laws. Tea is passed free of duty, we believe, only when imported from its source of production. It is amusing to find that while China tea is still imported into India (chiefly for consumption beyond the bounds of the empire), Indian tea to the amount of 61,000 lb. went to China in 1890, an exactly equal quantity being taken by Canada. Of the tea sent to the Persian Gulf, to which some Ceylon tea also goes, all is not consumed in Turkish or Persian districts. The foolish as well as iniquitous exactions by the Amir of Afghanistan as well as the prohibitive policy of the Russians has diverted much of what was formerly an important trans-frontier trade. Mr. O'Connor thus notices the export trade of India with Persia:—

"Exports of foreign goods to Persia are very much larger than those of Indian goods.

	Foreign.	Indian.
1889-90	... 1,225,603	497,102
1890-91	... 1,319,957	420,986

The increase under the first of these heads was mainly due to an expansion in the tea trade, Chinese

Java, and Ceylon tea having been shipped to the extent of nearly three million pounds to Persia from Bombay. This trade is to a large extent a diversion from the overland route by which Chinese tea used to (and still does in diminished quantity) go to Central Asia through Afghanistan. The region which is traversed northwards from Bush-hire and Bandar Abbas forms in itself a better and freer market than Afghanistan, and the transit of the tea to Meshed and places beyond is not so expensive and so subject to tolls and exorbitations as transit through Afghanistan.

The quantity of Indian tea sent to Persia also slightly increased, but it amounted to only 1,221,478 lb. compared with the 2,973,817 lb. of foreign tea exported."

The "foreign tea" alluded to is China, Java and Ceylon. In the notice of the export trade to Australia it is stated:—

"Our exports to Australia consist mainly of gunny bags, tea, and castor oil; bags being the staple of the trade, of the value of which they represent about 60 per cent. The exports of these have kept fairly steady since 1887-88 when, with good wheat harvests and wool clips, they more than doubled in one year. Last year there was another substantial increase. There was an increase also in castor oil, and a very satisfactory development in the export of tea. The exports of tea to Australia in the last five years may be noted here:—

	Pounds.
1886-87 ...	1,615,888
1887-88 ...	2,471,927
1888-89 ...	2,880,596
1889-90 ...	3,419,139
1890-91 ...	5,118,714

Rapid and large as this increase has been recently it is not so rapid as the increase in the exports of Ceylon tea to the Colonies. On this subject the following extracts are taken from a review of the tea season in the *Melbourne Argus* of the 24th July: "From Calcutta we find a large increase in shipments.

* * Large as this increase has been, it does not fairly indicate the increase in public favour of those fine teas * * From Colombo we have even a more rapid development of the exportations of teas to the colonies to chronicle, the shipments running up to 2,900,000 lb., as against 1,500,000 lb. and 146,000 lb. for the two preceding years respectively. The public taste has certainly taken rapidly to the more flavoured and softer teas of Ceylon, and there can be no doubt that not only China, but also India, has much to fear from the competition from Ceylon. The well-cured Ceylon teas are certainly most attractive, being remarkably flavoured, with good strength. Ceylon teas, however, have one serious drawback, and that appears to be their inferior keeping qualities; and, judging from the present year's receipts, this trade is certainly 'the jam tart trade' in tea, they are all better sold fresh than stale and flat, which, in many instances, from inferior manufacture they soon become."

We ought to supersede Chinese tea in Australia as we are doing in England, and it is not too much to anticipate that in another five years or so our exports of tea to the colonies, if the business is judiciously and perseveringly worked, should reach 15 or 20 million pounds."

In denouncing the fiscal régime of the ruler of Afghanistan, which has practically suppressed the transit trade from India to Central Asia through Afghanistan, Mr. O'Conor gives the following illustration, which casts even Chinese *Ukin* and other exactions into the shade:—

"Dues on Kangra tea, first quality, purchased at four annas per pound, per camel load of 450 lb., average value of the load R140.

10 Kabuli rupees at Dakka.	
15 do at Butkhak.	
37½ do at Kabul (town or import duty)	
37½ do " " (export duty)	
19 or 12 do as the tea takes the Shaikh Ali or the Bamian route	
7 do at Kalum	

9 do	at Khulm Tangi
7 do	between Khulm Tangi and Khilif

Total 138 Kabuli rupees equal to R106 or about 76 per cent.

The tea has further to pay 2½ per cent *ad valorem* at Bokhara, the value being the value there not what was the value at Peshawar. Adding the cost of the conveyance by camel between Peshawar and Bokhara (the hire of a camel from Peshawar to Khilif is Rs14) it is manifest that it is cheaper to ship tea from Bombay up the Persian Gulf and send it through Persia (where a 5 per cent duty clears it through the country.)"

Here we have the usual self-punishment of inordinate greed exemplified; but surely the patience of Britain with her "faithful ally" of Afghanistan seems to border on weakness. When Russia resolves on a transit trade through Afghanistan to India (and it may pay to send the kerosene of the Caspian by this route) she will adopt a different tone, we suspect.

As the conclusion of the whole matter it may be well for us to ponder the value of the criticism on the painting, that it would have been better, if the painter had taken more pains. We know what the difficulties are and that planters generally do their best with the means available to them. Those means, in the shape of improved machinery, especially air-changing appliances, ought to be multiplied and improved.

PHOSPHATIC MANURES.

Our planting readers have doubtless observed that a Colombo mercantile firm has advertised superphosphate of lime and dissolved bones at the identical price of R100 per ton. The most important ingredient of each, the soluble biphosphate of lime, is only as 12.53 per cent in the bones to 21.85 in the superphosphate. Otherwise stated the equivalents of ordinary bone phosphate rendered soluble is only 19.62 in the bones to 31.21 in the superphosphate. In plant food immediately available, therefore, the superphosphate (bone superphosphate, we take it for granted) has greatly the advantage of the dissolved bones. How the bones are entitled to be called "dissolved," when they contain 17.06 of insoluble phosphate, is a problem which, no doubt, chemical science can answer, as well as the fact that 3.20 per cent of insoluble phosphate resisted the action of sulphuric acid in the manufacture of the superphosphate. The insoluble phosphates in the bone (not really insoluble, but only becoming soluble slowly to the action of soil, moisture and plant rootlets) so far place the dissolved bones on a level in value with the superphosphate. But much more, we suppose, is the superiority of the superphosphate in soluble bi-phosphate and hydrated calcium sulphate (bone 31.68 to super-phosphate 47.21) counterbalanced by the fact that while the superphosphate contains only .29 per cent of ammonia, this valuable constituent in the bone is up to 2.78 per cent. Both are "valuable manures for tea," as claimed, but, in application, they would be improved by admixture with white oastor cake and such humic matter as may be available on the plantation. As the superphosphate is deficient in ammonia, we should suppose a small quantity of ammonia sulphate, or good fish manure would be a valuable addition to it. Otherwise, we should feel inclined to advise a proportion of at least twice as much oastor cake to be mixed with the superphosphate as with

the "dissolved bones" ? Besides estate rubbish and fresh jungle soil, if available, we have no doubt that burnt clay or peaty matter would be a valuable addition to the manures. The magnesia and alkalino salts, not of essential importance in themselves, are in nearly equal proportion in the superphosphate and the bones.

THE PRICE OF CIGARS AND TOBACCO GROWING.

A correspondent writes :—

"It is passing strange that, despite the low price of tobacco leaf, such extreme rates as those advertised in your paper of the 1st should still be obtainable for Manilla cigars, the advertised price in one case being as high as 100 per box of 50, or 18c. each.

"It is a great pity, I think, that those who went in largely for the cultivation of tobacco here, and lost heavily by it, did not introduce a few experts in the manufacture of the leaf from Manilla. Had they done so I feel sure they would have had no reason to complain of the results of their enterprise.

"Another mistake made by Ceylon growers was in not selling their leaf in the local market, instead of sending it home. I believe they would have got as much for it in the island as they did in Europe, and the cost of the long transport and home agents' charges would have been saved.

"But no one can feel surprised that recent attempts to grow tobacco profitably should have ended in failure, when he comes to consider the expenditure incurred, which was in many cases extravagant to a degree."

Then follow details of alleged reckless expenditure, which we should not be justified in publishing except on authenticated evidence.

THE CONSUMPTION OF TEA, COFFEE, AND COCOA.

A correspondent of the *Gracer*, writing about the consumption of tea, coffee, and cocoa, says:—Statistics as to the quantity of tea consumed in this country are somewhat conflicting. It is roughly estimated that 200,000,000 lb. are imported into this country, the value of which is £12,000,000. Mr. Bell, of Somerset House Laboratory, gives the amount of tea imported in the year 1880 as 208,500,000 lb. The abstract of the Customs report states the consumption per head for 1890 to be 5 lb., or 514. The consumption of tea has, from its first introduction into this country in the middle of the seventeenth century, steadily increased, and its price has also been steadily reduced. Coffee was first introduced at the same time as tea, but, unlike tea, its consumption has fallen off. In 1847 we are told that the quantity of coffee imported was 37,441,373 lb., but in 1880 it was only 32,480,000. Cocoa was introduced nearly at the same time as tea and coffee, and the consumption has continued to increase, though not to the same extent as tea. In the year 1810 the quantity of cocoa imported was 2,645,470 lb., in 1880 it was 10,568,159 lb. The great improvements in the methods of preparing cocoa are supposed to be certain to increase its consumption. In handling a small quantity of tea one would scarcely imagine that it was composed of volatile oil, wax, resin, gum, extractive matter, &c. Yet so it is. By distillation, boiling precipitation, filtering, and other chemical operations, the component parts can be learned and the chemical and physiological effects of tea as an article of diet can be correctly specified. Mr. Bell states the chemical composition of tea to be moisture, theino albumen, extractive matter, gum, pectine, tannin, chlorophyll and resin, cellulose, and ash. Mr. James Paton, in the *Encyclopaedia Britannica*, gives nearly the same parts in the same quantities. The composition of both coffee and cocoa is not very dissimilar from that of tea. Their dietetic value may be tabulated thus—tea is the most

refreshing, coffee is the most stimulating, and cocoa is the most nourishing. The solid food taken with these beverages will alter their dietetic value relatively; the solids being the principal source of nutrition. Theino is the most important part of tea; its chemical formula is $C_8H_{10}N_2O_2$. Mr. Bell states that theino contains nearly 29 per cent of hydrogen. Many hundred years ago a Chinese writer (Lo-Yu) gave his ideas on tea, which agree pretty much with the experience of tea-drinkers of today. Lo-Yu says:—"It tempers the spirit and harmonizes the mind, dispels lassitude and relieves fatigue, awakens thought and prevents drowsiness, lightens or refreshes the body, and cheers the perceptive faculties." As theino is the most important part in tea, so caffeine is the most valuable constituent of coffee; its chemical formula is exactly the same as tea. Coffee is more stimulating than tea, and has been long used by studious men to prevent sleep. Cocoa is more nutritious than either tea or coffee. In the form of an emulsion there is more of its solid parts utilized for nutrient purposes. Theobromine is the principal alkaloid of cocoa; its chemical formula differs slightly from tea and coffee— $C_8H_9N_3O_2$. Cocoa contains over 31 per cent of nitrogen, and is, therefore, more nutritious than tea or coffee. Mr. Paton says tea, coffee, and cocoa supply a want found to prevade all parts of the world; hence their increased consumption.—*H. and C. Mail.*

THE CEYLON TEA CROP OF 1891.

The figures for the first nine months of the year being complete, we are in a position to estimate with pretty near approximation the probable outturn of the year. We have had the quantities for each quarter added together, which, with the total for the nine months, are as follows:—

January-March...	14,913,082
April-June...	20,795,648
July-September...	16,986,499

Total...52,695,229

It will be seen that the average monthly totals for the first quarter were very close on five millions of pounds; then came a great increase in the harvest, raising the monthly average of the second quarter to close on seven millions, the highest figure yet being 7,075,081 lb. in June. The monthly average in the third quarter fell to 5,662,000 lb. The question now is what the quantity exported will be in the quarter on which we have entered. In the last quarter of 1890, the percentage of the whole year's exports sent away was 22.07. Our belief is that a larger expense than ordinary has been pruned this year and so will not be largely productive in the last quarter; but let us suppose that the conditions are fairly similar to those of the last quarter of the previous year. Then we think an average of $5\frac{1}{2}$ million pounds for each month of the quarter, or $16\frac{1}{2}$ millions total, will be about the figures realized. This would make the grand total export 69 millions. But the round figure of 70 millions may possibly be reached or slightly exceeded. This will be an unexpectedly great jump from 45,390,000 lb. last year, an excess of 24,610,000. It looks as if consumption would increase in fair proportion; but as increased production is likely to go on unchecked for years yet, efforts to push our teas and find new markets for them must not be relaxed.

ECHOES OF SCIENCE.

The past severe winter killed one of the white mangrove (*Avicennia nica*) sent to the Gardens of the Royal Botanic Society by the late Duke of Buckingham, when Governor of Madras. The dead plant has been turned into a museum specimen,

and the peculiar character of its roots can be well seen. The plant grows in the mud on the borders of tropical rivers, and it reclaims a good deal of dry land by collecting the mud about its stilted roots. To aid in this work the roots actually throw projections upward out of the water, which look like the teeth of rakes, and appear to serve the same purpose—that of gathering and retaining the mud and silt of the river.

A curious example of the natural "marching" of trees is reported from Lawrence County, Illinois, where two elm trees, standing 20 ft. apart, have bent over and coalesced into one tree at a point some 20 ft. above the ground. The united tree is very symmetrical and nearly 100 ft. in height. Wagons are driven easily through the triangular arch of its base.—*Globe.*

FEED FOR EGGS.

An egg is largely nitrogenous. The white is albumen, the yolk contains phosphoric acid and mineral substance and the shell is composed mostly of lime. The hen is a small animal. Eggs are not a miraculous dispensation, as they come from the food a hen gets and converts into eggs, the same as any animal converts its food into products. Corn alone is not a suitable food for the production of eggs, as it does not possess enough of the constituents to make eggs. Hens fed on such food will get fat. Hens like every other animal must have coarse food to distend the stomach and bowels and for this purpose cut clover, hay and cabbage are largely fed by many. These also contain material to make eggs. Skim milk is also just the thing for an egg food. To get eggs feed hens to produce eggs.

—*Rural Californian.*

[Bits of meat and minute fragments of bone are also good.—*Ed. T. A.*]

COL. F. D. CURTIS.

LEMONS AND EGGS.

Simple things are often of much benefit, and lemons and common table salt have much that is useful about them. Lemon juice and water, without sugar, will often times relieve one of a sick headache in a short time, and a half gill of lemon juice three times a day in a little water is said to be good for rheumatism. Nothing is so acceptable to a feverish person as lemonade, and for cough that refuses to be quieted, I have tried the following preparation with success: Take the white of an egg, beaten stiff; then add the juice of a lemon in which two or three lumps of sugar have been dissolved, and keeping it near at hand, take a tablespoonful of it at a time until relieved. A very good way of preparing lemons when they are plenty is to put them in cold water, letting them boil until they are soft, then squeeze the juice from them, getting more than in any other way, and adding the sugar to the taste, or to every half pint of juice put one pound of loaf sugar, and bottle. Another comfortable use for lemon is to bind a thin slice upon a corn that is troublesome at night, and repeat once or twice. It will greatly relieve the soreness. Then if the hands are stained from medicine, or any other cause, rubbing them with lemon after the juice is extracted, will restore them. Table linen or any such articles that become stained can be restored by the application of lemon juice and table salt, then placed in the sun, and stains removed by rubbing dry starch in at once, and repeating it.—*Good Housekeeping.*

NEW PLANTATIONS.—Tea is being planted rather extensively in the vicinity of Labugama, a well known dubash of Colombo having opened up a large extent of land for the purpose. The cultivation of popper and aracaunt is also decidedly on the increase, those products having, evidently, found a genial home. On one place especially, at the 20th mile post, pepper is looking grand; the young vines are loaded with green pepper.—*Local "Independent."*

NOTES FROM OUR LONDON LETTER.

CEYLON PLANTERS' ASSOCIATION AND PROSECUTION OF OFFENDERS IN THE PACKET TEA TRADE—FRAUDULENT TEA MARKS—LOW PRICES FOR, AND BAD QUALITY OF CEYLON TEA—MR. ROGIVUE'S MISSION—THE TEA TRADE BETWEEN CHINA AND RUSSIA—CEYLON PLANTERS' ASSOCIATION AND MR. LOUGH.

LONDON, Sept. 18.

Some disappointment is felt here at the determination of your Planters' Association Tea Fund Committee, recently conveyed to the Ceylon Association in London, not to approve of the proposal made by the latter body to prosecute a certain number of the offenders in the packet tea trade, who are in the habit of affixing misleading labels to their so-called packets of Ceylon Tea. We believe that no less than fifty such packets bearing different labels were sent out from home to your Planters' Association, and it was Mr. Gray's opinion that it would be a wise course to select a certain number of these issued by different traders in a single metropolitan district, and try a prosecution in a batch, so as to call prominent attention to the rogues by the magistrate of the district. The letter now received from your Planters' Association states that it does not think it desirable to follow Mr. Gray's advice, or, indeed, to take any present steps whatever. Of course, we know that there is an indisposition to "worry" the trade; but really the evil complained of has assumed such proportions of late that we here in London think it would have had a very valuable effect if some dozen or so of these offenders had simultaneously made their appearance in the Police Court to answer for their misdoings. We fear that if this growing evil is allowed to go on and assume larger proportions very serious injury may result to the reputation of your teas.

And this would have the more to be regretted because just now it is certain your teas are not advancing in popular favour, if we may judge from the low prices which have for the last two months been obtained for them in Mining Lane. Speaking on this subject during the present week with a very old and influential member of the trade, I asked him how it was that Ceylon tea fetched such low prices now; and his curt reply was: "Because they're all bad." We read in our *Observer* that your planters say that at certain seasons the leaf they pluck is very inferior; but the case seems to get worse every year, and the season alone does not account for this annually increasing deterioration. Cannot some of you suggest some remedy? so the state of things is very bad indeed. Everyone in the trade is calling out, and much Ceylon tea received is pronounced to be "rubbish." I heard of a case only this week of a purchaser who had bought largely of your tea, and who returned half of it on the brokers' hands as not being up to sample, and that sample itself was far below the average quality. Surely some of your planters might find a remedy for this state of things; for we on this side, although admitting a seasonal influence, do not think it can account altogether for the present state of things as regards our imports from Ceylon, some of the stuff sent home being really a disgrace to the island, and the greater part of it of a quality that the brokers will hardly look at.

A further subject upon which your Planters' Association has written relates to a desire for intelligence as to the progress making by Mr. Rogivue and for an account of his expenditure of the funds with which he has been supplied. My former letter told you all that could be learned by myself of Mr. Rogivue's proceedings, and I

should almost think that by this time he will have written direct to the Secretary of your local Association. It occurs to me that in this connexion you would be interested in the following extract given you with reference to the state of the trade between Russia and China in the teas grown in the latter country. The information seems to show that the endeavours making to introduce Ceylon tea into Russia are being met by increased activity on the part of the Russian agencies in China, which have evidently succeeded in stimulating the trade between the two countries to a very great extent. There is truth, no doubt, in the consular statement that the falling-off in the imports of China tea into London are to no inconsiderable extent due to shipments now being made direct from Chinese to Russian ports. This has been confirmed to me by several traders with whom I have conversed on the subject:—

THE TEA TRADE BETWEEN CHINA AND RUSSIA.—Russia is regarded as the stronghold and mainhope of the Chinese tea trade; while the British islands are consuming Indian and Ceylon teas, and the United States those of Japan, to the injury of China, Russia continues faithful to Chinese teas. The Commissioner of Chinese Customs at Hankow, in his last report, says that the tea trade with Russia is increasing annually, while it is decreasing with England, because while in former years tea was shipped first to England and thence to Russia, the tea dealers in Russia now have their teas shipped direct from China. Last year the trade with Russia would have been very large if the supply of suitable kinds had equalled the demand. Only the better kinds of tea can now be sold in Russia at a profit, as the demand there has undergone a complete change. Between 1877 and 1888 the exchange of the Russian paper rouble was very low; good teas were therefore dear, and the mass of the people could only afford to purchase inferior kinds. Since 1888, however, the rouble has steadily risen, and has now reached a value higher than any of the past 15 years. Tea, with other foreign goods, became cheaper and the people began buying tea of good quality, which, in spite of having cost higher prices in China, realized large profits. The market in China last year was entirely governed by the demand from Russia, which was very large and much in excess of the supply of the suitable qualities. In fact, the very best tea of the season (Keemuus) sold very cheaply, simply because they are a kind not consumed in Russia.

Quite a batch of letters came to hand by the last mail from your Panters' Association in reply to queries, &c., sent from here, and among these was one in which an attempt was made to soften down the annoyance felt by the Tea Committee of the Loudon Association at the letter first received which had rebuked the action taken by it in the matter of Mr. Lough's appointment as agent in Paris. The general feeling is, however, that although your local Committee disclaim having had any intention of judging the action on this side, that it really did so on insufficient and unsupported representations. Your Committee state now that it only invited reconsideration here at home on the basis of information conveyed to it; but we think that no one reading its first letter would limit their conclusion with respect to its tenour and purpose to any such view.—London Cor.

THE SALE OF COFFEE AND CHICORY.

Coffee planters will, no doubt, read with interest though not with pleasure, the following ingenious defence of the adulteration of coffee with chicory under certain conditions. It appears in a letter to the *Grocer* signed "Old Mocha." The law upon this subject, as upon many others connected with our trade, is an unknown quantity, throwing discredit upon the Imperial Government. The administration of this law and of the Weights and Measures Act, and others, is

left in many important particulars to the discretion of the Great Uppai, causing a vast amount of uncertainty in different districts. The contradictory decisions arrived at are sufficient to breed contempt for the presiding justices, and the system of rewards to informers and prosecutors is a temptation to unscrupulous persons to misrepresent the facts in order to get a conviction.

Now, how do many of the magistrates arrive at their decisions? They hold that a large percentage of profit amounts to fraud. But is this really so? We deny the right of magistrates to fix our profits. In the absence of a fixed limitation of the amount of the mixture, who is to decide the actual value of the article or the amount of profit under certain circumstances a person shall or shall not charge?

It is a singular fact, but none the less true, that the greatest number of prosecutions and convictions are obtained from little hucksters' shops, and it is the exception that respectable good-sized grocers are caught or trapped. Now I maintain that these little hucksters' shops are entitled to a greater percentage of profit than a large establishment would require, because they do not sell a large quantity of goods in a week, neither do they sell a considerable quantity at one time, but mostly sell in the smallest quantities possible, such as halfpennyworths. They may really not buy their goods in wholesale quantities, but perhaps at actual retail prices to sell again.

Now, I will show that the fraud found by the magistrates really does not exist, except in their own misguided imagination. Take the article tea: the keeper of the huckster's shop may buy one pound of tea at 1s 4d per lb. to sell at 2s per lb. If he should sell the whole of this quantity in a week, certainly the profit would not be an exorbitant amount towards paying rent and taxes. But in the case of coffee, what would be the component parts and the quality in an article purchased in the same way to yield the same results?

A coffee to sell at 1s per lb. would have to be bought at 8s per lb., and perhaps this quantity would take twice as long to sell as the pound of tea; so that if half a pound of this 8s coffee were sold in a week, the profit thereon would amount to 2d. Having arrived at this point, just picture to yourself the bright intelligent smile lighting up the careworn countenance of the proprietor or his wife if a real ready-money customer should come in and actually ask for a whole two ounces of coffee at 1s 4d per lb. Do you think it is in human nature to turn away such a splendid opportunity of obliging a new customer? The inspector's assistant thus procures the coveted article, and in comes the inspector, when explanations follow, and the inspector is now sure of his case. The usual proceedings are taken, and, rightly or wrongly, a conviction and fine are imposed.

Now a few words upon the component parts of the mixture usually sold. I think the fact can be proved by the best authorities that grocers buy a high-priced coffee to use for mixture. They hold that a high-priced coffee with a larger percentage of chicory produces a better beverage than a low-priced common coffee with less or without any chicory. Also, it is a fact, going to prove the same thing, that families grinding their own coffee buy a high-priced, and not a common low-priced coffee. Thus they would not be so foolish as to pay 1s. 8d. and 1s. 10d. and 2s. per lb. if one at 1s. per lb. could be procured to give them satisfaction.

Therefore what kind of coffee can we suppose the keeper of the little huckster's shop could obtain for 8d. per lb.? The only wonder would be, that there was any coffee at all in it. And yet these worthy magistrates, when trying the case, lift up their hands in holy horror at the dreadful fraud perpetrated!

This is the unvarnished truth of the majority of cases got up. It is somewhat amusing how these people scuffle out of the shop when they are really served with the article they ask for; sometimes they say, "Oh, I don't want to see it ground,"—which is perfectly true: they would rather see it mixed, and then buy it without notice of the fact.—H. and C. Mail.

FISH-CURING.

During the year 1890-91 there were 143 fish-curing yards at work in the Madras Presidency against 142 in the previous year. During the year two new yards were opened at Puthu-Ponani and Valanapilli, and the Manuapnam yard was closed, but since then five other yards at Byppilla, Konada, Kannur, Madialogam and Nambiakuppam have been closed, so that the current year opened with only 138 yards. 1,366,412 mannds of fish were brought to the yards to be cured against 1,181,058 in 1889-90, for which 196,426 mannds of salt valued at R1,32,111 were sold against 176,111 mannds valued at R1,16,278 in the previous year. The quantity of salt sold to each mannd of fish cured was 11.82 lb. in 1889-90. The increase of 6,698 tons of fish or 15.3 per cent brought to the yards to be cured is a very satisfactory development of the industry in spite of a bad fishing season on the whole of the East Coast. The rapid strides in the improvement of the fish-curing industry is evidenced by the following figures of fish brought to be cured for the past five years:—

	East-Coast.	West-Coast.	Total.
	Tons.	Tons.	Tons.
1886-87 ..	9,526	20,847	30,373
1887-88 ..	12,637	24,858	37,495
1888-89 ..	15,781	25,830	41,611
1889-90 ..	15,231	28,263	43,496
1890-91 ..	16,416	33,768	50,184

The quantity of salted fish manufactured locally in the several districts in the Madras Presidency during the year was 796,500 mannds, 30,787 manns were imported by sea, and 1,592 mannds by rail, making a total of 828,879 mannds. Of this quantity 98,275 mannds were exported by sea and 4,614 mannds by rail, leaving a balance of 725,900 mannds for consumption in the Presidency, exhibiting the fact that the bulk of the salt-fish cured is consumed in the Presidency. In South Canara and Madras the imports by sea are in excess of the exports, while in South Arcot, Tanjore, Tinnevely, Madurai and Malabar the exports exceed the imports. The quantity carried by rail both inwards and outwards is very small, but the latter is much in excess of the former. The expenditure incurred by Government on fish-curing operations was R52,963 against R45,031 in 1889-90 or an increase of R7,925. The increase is attributed to the expansion of operations and to the conduct of experiments in fish-curing on a larger scale. The gain to Government was R15,189-12-5 during the year and a total gain of R53,268-13-0 from the period of the commencement of the operations. A series of experimental operations in fish-curing was carried out by the Salt Department during the year, and 2,452 mannds of fish were operated on, for which about 397 mannds of salt were used against 541 mannds of fish and 103 mannds of salt in 1889-90. Government incurred an expenditure of R3,033-10-0 and realised R3,335-3-2, showing a small profit. The experiments were conducted on an extended scale and were undertaken to find out the quantity of salt required to properly cure fish.—*Madras Times*, Sept. 18th.

LONDON TEA LETTER

(From the *Indian Planter's Gazette*, Sept. 12th.)

HONOUR LIST.

FANCY LIST.

Mertings ..	2 lb. Golden Tips	5	0
-------------	-------------------	---	---

It needs no excuse that the Hukanpnkri 12 chests of Pekoe Souchong at 1s. 8d. should be found in the

Honour List, considering that these 12 chests complete the finest Invoice of the size ever received and sold together from India. The Flowery Orange Pekoe, was simply perfection, and had a beautiful glaze, showing great care in manufacture. Its weight for bulk was also very remarkable, indicating excellence in the rolling. In fact, it was evident, that every detail of manufacture had received the utmost possible attention, and that to begin with, the system of manufacture had reached the height of perfection. There is a similarity in the Teas of all the Panitola group of the Jokai Company's gardens which is a very striking illustration of how far one capable, directing mind, can go in stereotyping, so to speak, a certain type of quality and appearance, in the Teas of gardens situated miles apart, and upon very different varieties of soil; and possessing bushes of various *jéts*, and of course, different Tea-makers. This similarity, and excellence, common to all these gardens under one Superintendent, whose instructions are thus faithfully followed, go far to indicate that the "system of manufacture," so long ago hinted in these columns, has more to do with the quality of the Tea made, than all other conditions put together, provided the district be a Tea district, and the bushes not worn out. This is further borne out by the remembrance, that this very district (Sadiya Road) once upon a time was spoken of in Calcutta as having a soil which could produce quantity, but never quality.

JAMAICA CINCHONA.—A small consignment of cinchona from a private plantation in Jamaica was offered at this week's bark sales. This is the first shipment from that island that has been put up for auction this year. The total weight of it was only 67 lb., and if the offer had been accepted that was made for it, the total would have realised about 17s. As freights are high from Jamaica, and no less than 11s 6d carriage was paid for this little lot, cinchona growing in Jamaica does not seem to be an industry of much promise.—*Chemist and Druggist*, Sept. 12th.

TEA IN CHINA.—From Foochow we have the following tea news under the 22nd ult.:—The calling steamers during the past fortnight have been the "Patrocles," "Glenclesg," "Kiutuok" and "Nomon" for the German Mail, about 1/4 of a million lb. were shipped by these steamers, making the export to Europe to date 1 1/4 million lb. against 10 1/2 millions to the same date last year. The settlements in the interval have been 19,000 chests Congou, which, looked at in conjunction with the above mentioned fortnight's export, shows that there must be a considerable quantity of bought tea in the port unshipped, representing probably an accumulation for the next Australian steamer to sail about 5th proximo. Prices show but little change. Quiet though the market has been, the sales have been in excess of the arrivals, and with a moderate stock tea men have been generally firm. Common, however, must be quoted a nuce or two lower. The teas being settled at 11s. 8 per picul (53d per lb.) are barely up to "typo" standard on the average. The determined run on common teas at this time of the year is naturally having its effect on the question of total supply for the season. The tea men no longer stand to their assurance that it will be limited to 330,000 chests Congou; they admit the possibility of its being 10 to 15,000 chests more. It is thought, however, that this increase in the estimate of the total yield will not affect the probable total export. The latest arrivals include a considerable proportion of tea which can only be characterised "low ordinary coarse and new," a class not wanted in any of the markets to which Foochow ships, and if sold at all, will only fetch such a price as will deter any large supply of it coming down. The arrivals of Congou to date are 292,000 against 330,900; the settlements 208,000 against 187,000; and the stock of Congou is 89,000 chests against 152,000 chests at the corresponding date last year.—*N. C. Herald*, Sept. 4th.

SPECULATIVE DEALINGS IN INDIAN TEA.

It is now almost a year since the London Produce Clearing House commenced to register future dealings in Indian tea; and we believe that if the opinion of the tea dealers in the London Market could be gauged, they would, with perhaps one or two exceptions, unhesitatingly express their regret that this new element of speculation was ever introduced. Opinions vary no doubt as to the ethics of "future" dealings in produce, as well as in stocks and shares; but we are not at present concerned with this view of the question, which we imagine every man must settle for himself. It is our business to collect information from every reliable source, and focus it so that our readers may form their own judgment, and act as they think best. And it is because we see at present some symptoms in the market of a disposition to make what are called "bear" sales of Indian tea that we venture to draw the attention of those interested to the necessity of combined action to avoid an undue disturbance of values.

There are those who say that there is a moral difference between a "bull" purchase and a "bear" sale; but as we said before we are not concerned with the ethics of the question at present, and we will merely say that the conduct of a "bear" after having sold what he never possessed is generally directed to circulating injurious reports and otherwise seeking to batter down the value of stock held by *bond fide* owners—in short, he tries to depreciate other people's property to make thereby a profit for himself. It is somewhat unfortunate that just now the large supplies of Indian and Ceylon tea have tended to depress the legitimate market and rendered the "bear" game more easy. It is an open secret that some of the brokers in the market are operating for themselves in this direction. And it becomes, therefore, most important for planters and importers to consider whose advice they accept as to how and when they should offer their imports. It is manifest that if the market is overdone with nearly 20,000 packages in one sale and only 5,000 packages the next, there will be more or less irregularity in the prices, which will injure the interests of those importers whose teas are offered in the larger sale. It is known that the shipments from Calcutta were very heavy for the last fortnight of August and the first fortnight of September, and naturally the "bears" are jubilant at the prospect of covering their shorts in the anticipated panic and utter demoralisation which they reckon on if all the weight of tea is put upon the market with unreasoning haste. There was last season an attempt made to regulate the supply in public sale, so that it should not exceed 15,000 packages in one day or 35,000 packages in one week. The 35,000 total for the week has not yet been reached this season, but this week nearly 20,000 packages passed the hammer on one day with a manifest tendency downward. No time should therefore be lost in coming to some similar arrangement, as importers cannot be constantly in the salerooms watching the fluctuations of the market or the nature of the buying; consequently an "automatic feed regulator" (as somebody styled it last season) seems in every way a desideratum. The situation is no doubt somewhat peculiar as regards heavy supplies of Indian and Ceylon teas, but they are both steadily displacing China teas. The stocks of all kinds of tea on Aug 31 were only 1½ millions greater than last year. Shipments have practically ceased from the Chinese ports for this season, and it is exceedingly probable that the home and shipping demand will be quite equal to taking off every pound of Indian and Ceylon tea that comes here this season, especially at the low rates now ruling; but the supply should be regulated.—*H. and C. Mail*, Sept. 18th.

Messrs. Gow, Wilson & Stanton's Tea Circular.
—In the circular dated Sept. 25th, our readers are requested to note the following correction:—The total Indian average for the week should read, 28,151 pkgs. at 93d; the Syihet and Cashar average should read, 10,715 pkgs. at 84d.

A NEW MATERIAL FOR TEA PACKING.

A new material for lining tea chests has long been talked of, and it is now introduced. In an advertisement which appears in our columns, planters and tea importers are informed that the new material "costs half the price" of tea lead, that it "answers the purpose admirably," and that it has been "tested and approved by experts." Our representative called upon the makers, Messrs. Edward Saunders & Sons, Limited, of 81 and 83, Cannon Street, and from them we learn that in addition to the advantages thus claimed for this new material, it is impervious to damp, will bear boiling without injury, it does not break nor crack, and, of course, is very much lighter than lead, weighing but one-fifth the weight, an important matter where freight is concerned. The makers claim that they have been testing its thorough efficiency for years and now that they have proved the new material, they place it in the market with confidence.—*H. and C. Mail*.

HOW LEAF DISEASE HAS LESSENED THE PRODUCTION OF COFFEE IN JAVA, notwithstanding the advantage of rich volcanic soil, is shown in the following figures, given by Dr. Burck, in his paper suggesting remedies:—

Average yearly production	Samarang.	Cheribon.	Madison.
In 1864-1868 ...	52,700 pikuls	24,900 pikuls	60,300 pikuls
" 1869-1873 ...	51,550 "	23,500 "	61,700 "
" 1874-1878 ...	49,200 "	22,700 "	58,600 "
" 1879-1883 ...	50,500 "	24,600 "	64,400 "
" 1884-1888 ...	27,300 "	11,760 "	33,275 "

COFFEE AND CINCHONA IN JAVA.—According to information received lately the coffee crop in Java will be much more than in the preceding year. The Government crop will be about 385,000 piculs, against about 160,000 in 1890; and from private undertakings in the east portion of Java the report of larger crops are given, which will be above the estimate. An interesting statement shows the increase of the cinchona bark cultivation in Java by private planters. The following figures exhibit the exports from Java for the last five years:—

	Private	Government
	lb.	lb.
1890-91 ...	6,383,561	533,255
1889-90 ...	4,579,787	541,481
1888-89 ...	3,599,525	815,506
1887-88 ...	3,124,924	617,101
1886-87 ...	1,569,842	660,433

—*L. & C. Express*.

INDIAN TEA OF LOW QUALITY.—We suppose it is the generally good quality of Ceylon tea which led to such severe denunciations on recent descents below standard. But, due to similar causes no doubt, Indian has also been of inferior quality and has sold at prices as low as the lowest Ceylon. Confirmatory of this statement, we quote as follows from Shepard & Co.'s circular of September 25th:—

Indian.—Offerings have exceeded those of the previous fortnight by some 4,000 packages. The general quality of supplies fails to show improvement, and prices for all common and ordinary liquoring Teas have been gradually tending downwards, so that quotations of 5½d, 7d and 8d have now been recorded for the lowest grades of Sonchong, Pekoo and Broken Pekoo respectively. Good medium to fine kinds are generally well competed for at about previous rates, and for a few parcels of very choice Darjeeling Tea long prices have been obtained.

We take this opportunity of correcting a mistake in a paragraph on Ceylon tea which had sold at 5½d inserted in yesterday's paper. The extract was from a Melbourne letter,

COFFEE PRODUCTION IN INDIA.

Although in India, as in Java, leaf disease has not acted so suddenly and disastrously on coffee, as has been the case in Ceylon, it is evident that much mischief has been done as is still being done by the leaf fungus. Mr. O'Connor's notice of this article of export in his review of the export trade of India is as follows:—

Notwithstanding the stimulus of prices in the European market which have ranged very high during the last few years, and still continue to range high, the exports of coffee do not increase as will be seen from the figures subjoined:—

	Owt.	Rx.
1886-87	370,458	1,502,251
1887-88	273,775	1,529,680
1888-89	365,299	1,824,243
1889-90	239,795	1,459,872
1890-91	233,451	1,454,985

The trade during the last decade remained stationary, until the last three or four years when it began to decline, although helped by high prices in London and the low rate of exchange which, it is still supposed by some, is advantageous to the tea and coffee planter. Indian coffee, however, has doubtless difficulties to contend with. Unlike Indian tea, it is not superior to the coffee of other countries with which it competes in Europe, and the ravages of leaf-disease have been very serious.

It thus appears [that the exports have gone down from 370,000 owt. to 233,000 in 6 years. Mr. O'Connor is mistaken as to the quality of Indian coffee. It is far superior to the generality of Java and Brazil. Indeed Mr. O'Connor himself shows, in dealing with the trade to Arabia and Turkey, that South of India coffee finds its way via Bombay to those countries, and is there drunk by visitors as superior to anything of the kind in the world.

A DECOCTION OF TOMATO LEAVES AS A CURE FOR TEA BLIGHT.

We know that the tomato fruit possesses active properties, beneficial in the case of torpidity of the liver, we believe. But we were not aware that any special alkaloid existed in the leaves. This would appear to be the case, however, judging from correspondence which we quote from the Calcutta journal *Capital*. Can any correspondent help us to an analysis of the tomato plant? If the decoction of the leaves suffices to destroy red spider, there can be little doubt that it would prove equally destructive to the spores which it touched of *Hemileia vastatrix*. But there is not only the expense of the application but the question of infection from neighbouring plantations not similarly and simultaneously treated. From Mr. Weston's limitation of "creeping things" it seems doubtful if the cure would reach the case of the far more formidable helopeltis. Happily our tea is exempt generally from any of the pests which are often so destructive in India; but, in case of eventualities, we consider it our duty to lay before our planting readers all information of this nature which reaches us. Planters can judge for themselves of the probable value of the antidote now submitted to public notice. As red spider is only "a creeping thing" the exemption of tea for eighteen months can be understood. Such exemption could not, probably, be calculated on, were the plague us operated on either helopeltis or *Hemileia vastatrix*.

"Singell," whence Mr. Weston writes, is an estate in the Kurseong division of Darjiling, at an altitude of about 3,500 feet.

THE CLARENDON AND CARLABECK TEA FACTORIES.

Upper Abbotsford, Nanuoya, Oct. 9th.

Last Wednesday afternoon I had the pleasure of visiting the two fine factories of Clarendon and Carlabeck. The former is fitted up with turbine, 16-tray sirocco, rollers, sifters, &c.; but its great charm lies in its perfect finish. All the pillars are of dressed stone cut to exact sizes, so that whichever way one looks a perfectly level row meets the eye. From top to bottom the factory, like the estate, is as spick and span as a new pin, and does Mr. Black the greatest credit.

A Carlabeck we found Messrs. Jackson, Halliley and Cassio up to their eyes in oil erecting new machinery. The factory has practically been all built anew under Mr. Jackson's own supervision, iron uprights and girders having been got out from England. The dimensions of the house are about 100 ft. by 50 ft., and it is to be the model factory of Dimbula, I believe. I was fortunate enough to see the smaller Britannia at its second day's work, and the perfection of the work was simply marvellous. As we five Europeans and some hundred coolies watched the automatic action of the revolving trays, each turning upside down when its work was done and being banged by a batten to thoroughly empty it, we looked at the maker, and (he'll excuse me if I say that) "etill the wonder grow, that one small head should carry all he knew." The popularity of the Britannia is proved by some thirty having already been booked. The fans send a perfect hurricane of draft through the house. I need hardly say that turbine, rollers, sifters, and all else, are erected on a thoroughly scientific and methodical system throughout. Who says Ceylon tea is not paying?

Only 0.13 of rain yesterday.

Seismic cyclones simply scerning,
Today 's a glorious north-east morning;
No rain, no mist, no horrid hazes,
But cloudless suoshino, hot as blazes!

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Sept. 17th, 1891.

ANNATTO.—For a parcel of 65 bags of rather dull and somewhat damaged seed an offer of 1 1/2d per lb was declined today. The price is 2d per lb.

ARACA NUTS.—The parcel which was recently imported came up for sale today. The quality was rather disappointing, the seeds being rather worm-eaten and evidently badly dried. The whole of the 59 bags shown was bought in at prices ranging up to 37s 6d per cwt.

CINCHONA.—Very little South American bark was offered today. For 30 bales genuine flat Calisayo, 1s 4d per lb was refused, the limit being 1s 5d per lb. Good mossy broken Guayaquil quills were bought in at 1s 5d to 1s 6d per lb. A parcel of 12 bales badly damaged flat and split quill Maracabo sold at from 2 1/2d drawn to 1d per lb. The case of Jamaica bark in red quill, rather broken, offered at the last bark auctions, sold at 3 1/2d per lb today. Cablegrams from Batavia state that the exports of cinchona bark from Java in July were 1,300,000 Amsterdam lb., and in August 750,000 Amsterdam lb. The total shipments of cinchona from Java for the season ending June 30th are now to hand, and show that the estimates hitherto given were much below the mark. The official figures are as follows:—

Season	Private Plantations		Government Plantations	Total
	Amsterdam lb.	Amsterdam lb.	Amsterdam lb.	
July 1st				
1890 to June 30th, 1891	6,323,561	553,255	6,876,816	
'89	4,579,757	541,481	5,121,238	
'88	3,599,525	815,503	4,415,028	
'87	3,124,924	817,101	3,742,025	
'86	1,569,842	660,433	2,230,275	
Up to the present	a total of 826 packages bark only is announced for next Tuesday's auctions. It is composed			

of 151 Ceylon, 325 East India, 77 Java, and 273 South American Calisaya barka.

ESSENTIAL OILS.—Three quart bottles of fine oil of Lemongrass from Domhilea (W. Indies) sold with furious competition at the fancy price of 1s 9d per oz. Native East Indian is worth 1½d to 1½d per oz. A transaction of 100 cases September-October steamer shipment at 1 11-32d per oz "c.l.f. London" has recently been reported. Citronella oil remains dull at ½d to 11-16ths d per oz on the spot, with very little business.

QUININE.—No business whatever has been reported this week; but on Friday last a lot of 5,000 oz Pelletier's brand, in tins, sold at 9½d per oz, which is the lowest price on record.

NOTES ON PRODUCE AND FINANCE.

A NEW TEA COMPANY.—The latest addition to the London tea companies is the Doodputtee Tea Company, Limited, which has just been registered, with a capital of £10,000 in £20 shares. The object is to acquire the estates known as Barra Doodputtee (including Chulta Kandy) and Chota Doodputtee, with the several tea plantations or gardens thereon, situate in the District of Cachar and sub-district of Silchar, province of Assam, India, and to carry on the business of tea and coffee planters in all its branches. The first subscribers, who take one share each, are:—D. Macneill, 50, Old Broad Street, E. C.; J. Mackinnon, 50, Old Broad Street, E. C.; S. Macleay, 50, Old Broad Street, E. C.; C. Reiner, 50, Old Broad Street, E. C.; E. A. Jack, 85, London Wall; J. Hutton, Oakleigh, Perry Vale, Forest Hill, Kent; J. B. Taylor, West Hall, Upham, Bishops Waltham. There shall be not less than three nor more than five directors. The first shall be James Davidson, E. A. Jack, and J. Mackinnon. Qualification, fifty shares. Remuneration, £300 per annum, with an additional 5 per cent after payment of 8 per cent dividend.

LAST WEEK'S TEA SALES.—Commenting on last week's tea sales, the *Grocer* says:—A rather gloomy view pervades the whole market, and dealers are looking for lower prices. The reason is, we believe, there is too much tea on the water at the moment. Export demand is very quiet, and further smash-out sales are expected. As regards low-priced teas, we doubt if we shall see them much cheaper, and the losses on the finer grades are so great that those who can afford to hold on will do so, in anticipation of better times. We have already begun the season on a very low level. Monings are agreed on all sides to be good, while Foochow kinds began with such a bad character that buyers cannot see the good value that is being offered them considering the price. Such a market must affect the total export from China, and many people say that present value will commend itself to the retail grocer, and to some extent stop the increasing consumption of Ceylon tea, more particularly when one takes into consideration the very poor quality of the bulk of the heavy offerings of Ceylon tea for the last two or three months. The Canadian and Continental demand for Foochow teas has been very small as yet, but there are signs of better times from those quarters. Russia does not help us yet much, but the value of the rouble is increasing, and holders of Ningehows here are plucking up courage. Dealers are holding no stocks, and if a demand does spring up later on, we should see a lively market. The supplies of Indian tea brought to auction have again been extensive, numbering in all 30,670 packages, which, in view of further considerable quantities to be put forward next week, met a very sluggish demand, and it was with unusual difficulty that the greater part was sold. The quality of several invoices was extremely poor, notably that of those from the Sylhet district, which showed a marked deterioration, and for many lots it was difficult to extract bids, so the teas were bought in or "passed." The dealers evinced no inclination to go into stock at present rates, but mostly contented themselves with merely looking on, and buying only such quantities and quantities as were suitable for their immediate requirements. This attitude on their part naturally caused the public sales to be more than usually tedious, and the weather being hot and stifling, many persons

who had been in the room all the while found it a positive relief when the auctions were over. Prices consequently received no uniform support, and in a majority of cases tended rather in favour of the buyer. Growers of Ceylon tea would do well to turn out a better class of tea than the trade have been accustomed to for some time past, as it is bound to pay in the long run. Larger breaks and fewer different qualities from each estate would also be desirable.

DOWN ON ADULTERATION.—In view of the work before it in connection with the Food and Drugs Act, the special laboratory long established at Somerset House for carrying out the analytical work required by the Excise Department, has been considerably developed of late. Other Governmental departments, recognizing the utility of chemical analysis for the conduct of their business, have had recourse to the laboratory for such assistance as they required in that way. The total number of samples analysed during the past year ending March 31 last, has been greater than in any former year, and amounted to no less than 43,426, or 1,246 more than in previous years. In the large majority of instances the results obtained supported the conclusions which had been arrived at by the public analysts.

THE LATE M. GRÉVY AND COFFEE.—The following story, published years ago, concerning the late M. Grévy, whilst yet President of the French Republic, may today bear repetition. He was returning home one morning after an unusually long ride in the country, and dismounting at a small roadside inn he asked the hostess to supply him with "a cup of coffee." Just as she was leaving the room he recalled her and asked if she had any chicory, being told that she had, he said he would like to see it. On her returning with it he asked her if she had any more, and learning that she had, he said "bring it here—bring me all you have in the house"—when this was done he said "now go please and make me a cup of coffee."—*H. and O. Mail*, Sept. 18th.

TEA TALK.

Writing from Hongkong, Mr. Edward Brodie says:—When I left Philadelphia, I thought I was a fair judge of tea. I had imbibed both it and the knowledge of it in large quantities from George O. Boldt, John Chamberlain and Delmonico. Now after having visited Ceylon, Formosa and the Amoy district I find that I know nothing and the three worthy gentlemen named knew even less.

We Americans don't know the first principles of making tea. The delicate leaf should never touch metal. It should be kept in paper, wool, glass, or porcelain.

To make it, put a small quantity in a porcelain cup, fill the latter with boiling water, cover it with a porcelain saucer and let it stand three minutes. Then if you desire to be an epicure, drink only the upper layer of the golden liquid, throw the rest away, rinse the cup and begin drawing the rova.

Don't use sugar any more than you would sweeten Chamberlain or pour molasses into Mumm's Extra Dry. Don't use milk! It ruins the flavor of the tea and injures the stomach. The cloudiness produced by adding milk to tea arises from the action of the tannin upon the casein, and is, chemically speaking, pure leather. An old maid who drinks a dozen cups of this mixture a day swallows a hundred pairs of boots and a section of extra long leather hose during her lonely life of fifty years. Above all things don't boil tea. The heat drives off the perfume, spoils the flavor and extracts the tannin, the astringent principle. If the boiling be done in a tin or iron pot the tannin attacks the metal and makes the liquid black, this fluid is simply diluted ink. Never let the tea stand except in a tightly closed porcelain pot. Standing changes it from a delicious, wholesome beverage to an ill-tasting bitter liquor. Mothers make it in small quantities and make it often. Mother-in-laws bear many good housewives say, "It noods no ghost to tell us this," and yet there are thousands who do need advice on this simple subject. In summer,

when you want to cool off quickly, sip the tea boiling hot, with a slice of previously peeled lemon, or nicer still, of orange, without the rind, floating in it. In winter, especially when you have a cold and require a stimulant, add a wineglassful of arrack to it and drink it down as hot as you can stand it. It brings out a profuse and healthful perspiration when punch or hot Scotch fails to thaw you out.

Beware of green tea! It is an abomination and a fraud. A Chinese coolie wouldn't give it to his pig. He will give that patient porker dead rats, old hoots and other offal and such unconsidered trifles, but he draws the line at green tea. In the first place it is simply the unripe leaf and bears the same relation to the real article that the "little peach of emerald hue" does to Delaware's delicious fruit in its richest ripeness. It has the same effect upon the stomach and abdominal nerves as in the case of poor "Johnny Jones and his sister Sue." The green tea of commerce derives its rare color from being cured or rather killed, on dirty copper pans, from being mixed with woods and herbs, from being stained with indigo and chrome yellow, from being colored with verdigris, grass-juice or chlorophyll. Every green dye known to commerce has been used to produce the much admired but death dealing color excepting it may be Paris green. As soon as the use of that poisonous substance will give a profit of a cent a pound you can wager it will be liberally used by the mercenary Mongolian merchant and the much more mercenary cultured European tea trader.

I'll venture the statement that there is no fine tea in the United States. What goes to our country is the cheap stuff used here by the coolies and jailinmates.

When an American housekeeper pays \$1 per pound for her Oolong or English breakfast she is buying what is sold here for 25 cents. No really good tea is sold here for less than \$1 per pound by the wholesale. If laid down in the market at home it could not be sold for less than \$1.75.

This \$1 tea is the usual article for clerks, poor tradesmen and mechanics. For the well-to-do, the official class and notability are finer pickings that run from \$1 to \$50 per pound. The only Europeans who purchase these high-priced leaves are Russians and a few connoisseurs in France, Germany, Austria, Spain and Turkey. The bold Briton permits patriotism and his purse to guide his palate and uses the vicious, vitriolic horrors of Ceylon and India. Good Uncle Sam patronizes a Cheap John, who gives away to each purchaser a \$2 cup and saucer with every 25 cent pound of tea.

The tea plant is as sensitive and delicate as a West Walnut street helle. It flourishes best on a mountain side, where it is neither very warm nor cool, where the soil is dry, but the rains and dews are frequent, where the force of the wind is broken by adjacent woods or hills, where there is a maximum of sunlight and, according to the Colestials, of moonlight and where the surrounding ground is kept free from weeds or other vegetable growths. There are farms in Formosa, Fö Kien and other tea districts where those conditions exist unchangingly, whose tea crop is as famous and distinctly known in the eastern world as the various chateaux of France are to the wine experts of Europe. Just as the millionaires of Europe control certain vineyards, so do the millionaires of the Flowery Kingdom control tea plantations whose annual output is worth a king's ransom.

Another point of the many we have to learn from the Chinese, is the proper mode of packing the leaf. That which goes to America is dumped as soon as it is "fired," burning hot, into a lead hood box, the lead is soldered and the airtight coffin is sent around the globe in the hot hold of a steamer. The tea sweats and undergoes many changes which alter its flavor and vitiates its quality.

The Mongolian packs the poorest kind in strong paper packages and these in turn in mortuary lead; better kinds in soft-tin paper-covered boxes; still better ones in silver-foil inside of one pound cases made of split sun-dried bamboo, and the best in porcelain jars and vases.

He packs in eighths and quarters of a pound, so that if a few leaves are improperly treated or not cured, they

will not contaminate much surrounding tea. The Russians compress the tea into bricks, or cover it with silver-foil and many paper wrappings; or else put it in glazed jars.

The principle is the same—the sub-division of the tea, and the prevention of risks attending larger packages or in bigger bulk, such as heating, sweating and moulding.

This principle we have yet to learn and apply. But ah, the exquisite pleasure to be found in a cup of truly fine tea. The colour is a delicate gold; each leaf unfolds into a perfect olive oval; its fragrance fills the banquet-hall, delicate and yet penetrating, dainty but distinguishable above all other perfumes; and the flavour! The famous Clover Club Punch pales into dim distance in comparison to this "cup that cheers." Words cannot describe the delight in a brow of fresh Formosa tea. It fills the system and makes every nerve thrill with joy. It lingers on the palate for hours. And "the next day," think of it, O votaries of Bacchus, the brain is clear, the body all alert and the soul ready for the battle of life.

I never taste the fragrant leaf without recalling Edna Standard's lines,

"With kindred souls in many a spot
I've had good tea; from urn and jar,
From caddy, Cha-boo, English pot,
And fiery Russian samovar.
But none so fragrant or so sweet
As that which from thy hands today,
With some enchanter's art replete,
Drove every thought of care away."

PREVENTION OF BLIGHT IN TEA.

(From *Capital*, Sept. 30th.)

We are indebted to the Acting Secretary to the Indian Tea Association for a copy of the following correspondence on a cure for red spider and possibly other blights:—

From J. BUCKINGHAM, Esq., to J. H. H. ROLFE, Esq.,
Secretary, Assam Branch, Indian Tea Association,
(dated Amgoorie, 21st July, 1891.)

I have been favoured by Mr. Bruce, of Messrs. Kilburn & Company, with some correspondence between Mr. Simon of Messrs. Hoare, Miller & Company and Mr. Weston of the Singell Tea Company regarding a cure for red spider and probably for other blights.

I send you the letters for publication, and it would be interesting if experiments were made and the results communicated to you.

From A. J. SIMON, Esq., to W. WESTON, Esq.,
dated Calcutta, 6th October 1890.

I should be much obliged if you would, when you have leisure, let me have a report on the tomato decoction prevention against blight. You will know better than I do what points should be specially mentioned, but I may say I should like them to include:—

1. What blights may be prevented by it?
2. To what extent each is affected and for what period?
3. When is the decoction applied, how, and in what quantity?
4. How is the flushing of the bush affected?
5. Is the health of the bush impaired?
6. Is the leaf affected in color, taste, or otherwise?
7. What labor is required to apply the decoction?
8. Is the tomato leaf easily obtainable?
9. How is the decoction made?
10. What are the advantages, if any, that can clearly be attributed to the use of the decoction?
11. What are the disadvantages of the same?

I hope this list will not appeal you, and that you will frankly give your opinion as to the value of the treatment. While on the subject I should much like to know whether you think the outbreak of your garden has been affected in any way by your experiments, if so, to what extent, and whether you look for any further result. I am sorry to give you so much

trouble, but am anxious to know whether the system is worth developing.

From W. WESTON, Esq., to A. J. SIMSON, Esq., dated Singell, 30th October 1890.

I now send you my report on the tomato decoction as a cure for certain blights. I will answer all your questions first, and then add a few remarks after.

1. I have only treated "red spider," but am of opinion that all blights which crawl (have no wings) could be prevented by this treatment.

2. So far the hloek of bushes treated last year and this for "red spider" have not been attacked again. The 1889 hloek has now been free for seventeen months.

3. I consider the decoction should be applied as soon as the first signs of the blight appear. The best and quickest method of applying the decoction is with syringes with rose heads. Syringe the bush thoroughly morning and evening. The quantity depends on the size of the bush.

4. By the destruction of the blight, the bush is enabled to flush or throw out new shoots quicker. That is, it continues to flush in its natural manner.

5. In no way is the health of the bush impaired by the use of this decoction.

6. The leaf is in no way affected in color, taste, or otherwise.

7. Taking 4,840 hushels to the acre, the cost of labor would be not more than R10 per diem (an acre) this is giving 50 large bushes to each child to thoroughly syringe morning and evening.

8. Yes, in this district one might say it grows wild, for when once planted, the plants come on with very little attention.

9. Take 80 lb. of tomato leaves and stalks (bine), throw a portion into a cask, and pulp well with a long wooden mortar. Continue adding till the whole of the 80 lb. is pulped, then add 40 quarts of water and mix well. The decoction is now ready for use. *Old leaves and bine* which are stringy are useless.

10. The advantage derived in treating "red spider" is most important:—

Firstly, it prevents the shedding of leaves by destroying the spider before it wears them.

Secondly, by preventing the shedding of leaves the plant is enabled to gather its necessary quantity of dew at night during the dry months, and consequently it has the strength to flush.

11. The disadvantages are nil.

My experiments have not been on a large enough scale for me, to form an idea as to what extent the outturn has been affected, but there is no doubt that it would be greatly benefited by the prevention of the spreading of the blight on its first appearance.

I consider the tomato decoction as a preventive is better than the tobacco decoction used at home for the destruction of blights in "hop gardens." With reference to my answer to your question No. 2, of course we have had an unusual year of weather in every way, which undoubtedly has affected all blights as well as the quality of the leaf; and taking this into consideration, as well as the small area at present treated, I would not like to say more without making another experiment on a large scale, say 10 acres next year. But one thing I am certain of is, that the decoction of the strength given in para. 9 kills "red spider."

No. 6. The leaf from which tea is made can in no way suffer by using the decoction; for as long as the bush is suffering from "red spider," it does not flush, and as soon as the pest is destroyed the treatment is discontinued.

If I have not answered all the questions to your satisfaction, let me know, and I shall only be too pleased to give you any further particulars you may wish for.

From A. J. SIMSON, Esq., to W. WESTON, Esq., dated Calcutta, 11th November 1890.

I must apologise for not having yet thanked you for the full report you have sent me on the tomato treatment of blight. It is very complete, and I am much obliged for the trouble you have taken to make it so. One point strikes me, however, and that is the expense which you put at R10 per acre per diem. This, at

first sight, appears prohibitive as it seems for a garden of 500 acres R5 000 per diem or per annum R18,25,000. But I know it has not to be done every day even during the season, and should therefore like to know how many days' treatment on an average you find sufficient in the first instance, to rid attacked hushes and how often the decoction has to be applied afterwards to keep them free. You say 1889 hloek has been free for seventeen months, from which I infer that the effect carries on beyond one season even. In reference to this question it would be interesting to know what you considered the average expenditure on the treatment per acre per annum, and whether you think such expenditure compensated for by the increased yield of leaf, if so, to what extent.

I am sorry to trouble you further, but think my information will be complete if you can kindly reply to these points.

From W. WESTON, Esq., to A. J. SIMSON, Esq., dated Singell, 3rd December 1891.

In answer to your question how many days' treatment I found sufficient in the first instance to rid attacked bushes?

Eighteen to 27 days' treatment entirely got rid of the spider, but I believe if a stronger decoction was used, it would act quicker, and at the same time not injure the hushes or leaves. The hushes when once treated have not been attacked again, and so far the treatment shows a perfect cure.

In answer to your question referring to duration of time the effect lasts, and the average expenditure on the treatment, I take the average expenditure on treatment per acre, R130 per annum, and if this means a permanent cure, which it so far shows in the 1889 hloek, which has been free for over 17 months. I consider the expenditure would in every way be compensated for by the increased yield for no red spider would mean one's getting the proper outturn from each acre of tea every year after the cure has been effected, which cure so far seems permanent.

With reference to your figures of expenditure on a 500 acre garden treated for "red spider," it would be impossible for the whole area to suffer at once, as red spider starts on a portion of a hloek or block, and spreads if left alone; therefore, if the attacked parts are treated with the decoction on its first appearance, the spreading is prevented, and the expenditure in consequence is brought down to a minimum.

Should we suffer from red spider next season, I intend trying a strong decoction which, I have no doubt will cure in a smaller space of time, and of course reduce the expenditure per acre.

If I have not answered all your questions as you wish write and let me know, for I am only too pleased to answer them.

THE CULTURE OF COFFEE, &c., IN SINGAPORE.

Mr. Ridley, the Director of the Straits Gardens and Forests, in noticing Dr. Burek's papers on leaf-disease in Java, writes:—

All who have seen a view of the coffee fields in Ceylon, must have noticed the entire absence of any hedges or jungle breaking up the enormous tracts of coffee cultivation. The ground is, it is true, very undulating and hilly, but there is no attempt made to separate the fields at all by hedges. The whole country is open to the sweep of the prevailing wind to carry the fungus spores from end to end of the island, and, indeed, the undulating nature of the ground is in favour of the spread of the disease. Professor Marshall Ward, when he was investigating the disease in Ceylon, pointed out this very thing, and urged the formation of hedges. It is not probable that this simple method would have so far arrested the disease as to save now ruined cultivation in Ceylon, but it would, doubtless, have lessened the violence and rapidity of the attack, and given some chance of combating the disease, by breaking up the

whole into more manageable plots. It must be remembered that it is very rare to find any one species of plant growing in masses together unmixed with any other in a natural state. The effect is somewhat like that of herding many animals of one kind together in the same space. However, for crops such as coffee it is essential to do this. They require to be grown under unnatural conditions but as this is unavoidable, it is still possible to break up the plantation at least to a small extent by having belts of jungle, here and there, running through the plantations. The quantity of coffee lost by not putting these belts under cultivation is trifling compared with the advantage to be derived from them. These belts will arrest the spread of fungus spores, and blight. They will also be of signal use in attracting the insectivorous birds which will aid to keep down the insects which injure the coffee, and they will also be useful as supplies of sticks, poles, &c. required from time to time in the plantations. It is of course possible that monkeys and musangs will resort to these jungle patches, and sally forth at night to devour the coffee, but they are tolerably easily kept down in small woods and it is usually when there is extensive forest near the plantation that they are so injurious. Where the jungle has been destroyed, and where there are bushes to make screens, I would suggest the planting of such trees as *Adenanthera pavonina*, *Saman*, *Jambus*, *Erythrina*s, *Jacktrees*, etc., in thick rows, so as to break up the plantations. Nor would I restrict the use of Jungle belts to the cultivation of coffee only. With all crops cultivated on a large scale here, I think it would be advisable to break up the plantations, if possible. It may be that with some cultivation no enemy worth considering is yet known, but no plant is entirely free from enemies either fungal or insectal, and although it may seem strange to say that a small jungle belt can and will act as a defence against strong winged insects, yet such is the case for the insects when they rise in the air high enough to clear the jungle, are very liable to be borne far away over the plantation, and if even they do invade the plantation they come but a few at a time and can be easily dealt with. The peculiarities of insect attacks on crops here must, however, be treated of at some future time.

But with respect to Dr. Burck's treatment with the sulphuric acid and scissors, and also the tobacco water treatment. At present the disease in the Straits does not seem to be sufficiently destructive to require such elaborate attacks upon it. For although it is very difficult to find a tree entirely free from attack, yet the Liberian coffee, unless a weak plant, seems capable of resisting any ordinary outbreak. Nevertheless, we may expect, should the cultivation ever become extensive, to find, as years go on, the disease becoming in time virulent, and this is the more likely as the soil in which we have to cultivate coffee is immensely poorer than that of Java.

Dr. Burck, it appears, does not attribute much of the violence of the disease to poverty of soil, yet I have doubts as to whether this may not have played a great part in the ruinous catastrophe of Ceylon. For a long period the same land had been under coffee. There was no rotation of crops, which in itself is impracticable for the most part with any crops except those of annuals or biennials. This constant growth of the same species of plant on the same soil, cannot but remove a large portion of the most valuable salts, and the plants must get gradually weaker, nor does there seem to be any reason to doubt but that weak plants are more liable to succumb to disease, whether animal or vegetable, than healthy ones. There is abundant evidence of this throughout both the animal and vegetable kingdoms. Of course thoroughly healthy plants may also be attacked, but they have a much better chance to throw off the disease.

I do not think Arabian coffee can ever be successfully cultivated in the Straits Settlements. It seems here to be very liable to produce "brush," that is to say, abnormal flowers, with minute, green, irregular sepals and petals, no stamens, and the pistil very small and apparently effete. I imagine this is due to the permanent dampness of the climate, and absence of any period of rest from growth. It appears to be a preli-

inary stage of what is known as phylloidy of the flowers, i.e., conversion of the part of the flower into leaves, instead of reproductive organs. This is common here also in certain orobids as *Phalenopsis Schilleriana*, which produces bulbs and leaves on the flower spike instead of flowers.

Besides the fungus, hemlock, the coffee suffers to a smaller extent from several destructive animals, among which are monkeys, musangs, a species of locust, the caterpillar of the bee-hawk-moth and a scale insect.

Of the monkeys the most destructive are the golden monkey (*Macacus sinicus*) and the black monkey (*Semnopithecus* sp.). The latter does not occur in Singapore but is common in Johore. These monkeys eat the fruit whole, passing the seeds uninjured, and the seeds passed by them are stated to be the best for cultivation. If this is correct it is perhaps due partly to the animals selecting the best fruit, but it is possible also that the seeds are absolutely improved by passing through the animal's body and so being manured, as has been shown to be the case with seeds of hawthorn trees swallowed by turkeys.

The musangs (*Fiberia malaccensis*) are even more destructive than monkeys, and a good deal harder to destroy, as they are strictly nocturnal and very skilful at avoiding traps. They may, however, be caught in traps baited with pieces of bananas. On one estate, I am informed, that these animals eat a pikul of coffee per diem.

The locust is a large species of grasshopper not yet identified. It is about 3 inches long, yellowish green spotted with black. The hind wings are pink and very conspicuous when it flies, which it does very briskly. It does not eat the coffee leaves, but injures the bushes by laying its eggs in the shoots. This it does by making a series of slits in the bark of the shoots spirally, in each of which cuts it deposits a long narrow white egg. The larvæ do not appear to injure the shoot at all, and probably leave the plant as soon as hatched. The shoots, however, soon wither and turn black and finally fall off, and this is certain evidence of the presence of the locust. As a rule it does not do much harm, but under certain circumstances it may become exceedingly abundant and injurious. It is quite a common insect here, but I have seen it most abundant in Johore. It must be caught in butterfly nets, and destroyed.

The bee-hawk-moth (*Cephonodes hylas*).—The caterpillar of this insect is very destructive to the coffee by devouring the leaves, and clearing bushes with astonishing rapidity. The moth lays its eggs upon the leaves of the trees and the caterpillars quickly emerge and commence the work of destruction, usually attacking weakly plants. When full grown the larva is about three inches in length and of a bright green colour. The head is small and dull green, the next segment is ornamented with a number of raised yellow dots, the rest of the body is smooth bright green, bluish above, along each side is a raised pink line and down the middle of the back runs a double white line from the head to the tail meeting behind the horn which, like most of hawk-moth caterpillars, this animal has upon its tail. This horn is curved and sharp, yellow with raised black dots. The last segment and hindmost feet are ornamented with raised yellow dots. The feet are furnished with tufts of hair, but otherwise the caterpillar is quite smooth. When full grown the caterpillar spins a web between the leaves and becomes a chrysalis. It remains in this state for about a fortnight and then emerges as the moth. The perfect insect is very beautiful, it is about 1½ inches long, the body dark green, the tail fan-shaped black and yellow. The wings are perfectly transparent except along the edges, which are of a dull dark red. It is very active and not very easy to catch, flying briskly about in the evening shortly before sundown, and may be seen sucking the honey from the coffee flowers, which it probably fertilizes, but as there are many other harmless insects which do this equally well it may be destroyed whenever met with without detriment to the fertilization of the coffee. It is most easily destroyed in the caterpillar state. The larvæ should

be picked off by hand and destroyed. They are most abundant in January, but I have taken it full grown in December, and seen the perfect insect at several different periods of the year.

The scale insect commonly called black blight (*Lecaninum coffeae*) is also very injurious at times especially to weak plants. It may be destroyed by the application of phenyl, diluted with water till it is of the consistence of milk or by shaking powdered lime over the leaves with a flower dredger. Phenyl water can be applied with aid of a squirt of bamboo, or an ordinary syringe. Many of the scale-insects are protected from most liquids suitable for killing them without injury to the plants, by the waxy secretion with which they are covered, which prevents the liquid actually touching the insect's body, but phenyl will penetrate the wax and attack the animal. The phenyl should be poured into the water and stirred up till it assumes the appearance of good white milk. A kerosene emulsion is recommended by the Editor of "Notes on Indian Insect pests," vol. i. p. 7. An emulsion resembling butter can be produced in a few minutes by churning with a force pump two parts of kerosene with one part of sour milk or soap solution in a pail, emulsions made with soap solutions being generally found to be more effective. The liquids should be at about blood heat. This emulsion may be diluted with from nine to fifty parts of water which should be thoroughly mixed with one part of the emulsion. The strength of the dilution must vary according to the nature of the insect to be dealt with as well as the nature of the plant, but finely sprayed in twelve parts of the water to one of the emulsion it will kill most insects without injury to the plants. It should be applied through a spray nozzle.

The white or mealy bug (*Pseudococcus adonidum*) is not as common here, but is also injurious. It should be treated in the same way.

I have received some specimens of coffee branches attacked by a fungus from Johore. This is quite a different kind to the hemileia. It seems to invade the bark of the branches filling them with a white mycelium and eventually forming a flesh-coloured crust on the outside of the twigs, which are then become black and rotten. It appears to be rather consequent on the death of the twigs from some other cause, and though it might perhaps spread a little to healthy parts is not much to be feared. It generally appears where the bushes are very crowded, and where the branches overlap, or where the locality is very damp. The dying and infected branches should be cut off and burned.

Mr. Ridley says nothing of a pest only less destructive than *Zemileia vastatrix*, viz. the white grub, which eats the feeding rootlets of Arabian coffee.

EXPORTS OF COFFEE AND PEPPER FROM THE WEST COAST.

Elsewhere we publish Messrs. Alston Low & Co.'s very interesting statement of the exports of coffee and pepper from the West Coast during the twelve months ending 30th June, 1891. Coffee and pepper form the chief staples of trade at Tellicherry and Calicut, and on the extent of these crops the prospects of business may be said to hinge. * * *

These figures show very clearly that it was not without some show of reason that the cry went up early in the year that "Arabia" was played out; At Calicut, the part of shipment for Wynaad, the Nelliompathies, Nadvattam and part of the Nilgiris, the exports of plantation dropped from 33,800 cwt. to 20,742 cwt. or by not far short of 50 per cent. Such a serious decrease may well have caused people to take the gloomiest view, for, if we are correctly informed, it is unprecedented in the history of the coffee industry in Southern India and ominously like what happened in Ceylon in the seventies. The present season, we are glad to say, has removed all doubt about coffee dying out in Wynaad, and the latest reports to hand tell of fair crops generally, and in some districts of first rate ones. Further, as in Mysore, new land is being cleared and put under cultivation,

Of course when dealing with Wynaad, it must be borne in mind that coffee is only one of the products cultivated in that district, and last year the return from cinchona (equalled if not exceeded the return from the berry. From Buppore coffee from the Oncherlony Valley and the Nilgiris is shipped, and here we find that although the exports of plantation coffee were 3,800 cwt. below 1889-90, and they were only exceeded by 330 cwt. in 1889-90, which shows that in those districts the season was not abnormally bad, still it is a terrible falling off from the 38,000 cwt. which were exported in 1886-87 and 1887-88. Turning to the northern ports, we find at Tellicherry there was a steady and serious diminution in the amount of plantation shipped since 1887-88, when it totalled 36,000 cwt. Both that season and in 1885-86 some 10,000 cwt. found its way to this Malabar town, to be cured, which, if crops had been smaller, would have gone to Hunsur so that Tellicherry shipments cannot be looked on as a fair criterion of the crops in South Coorg during the past six years. Statistics from the Onring Works at Hunsur and Bangalore are necessary to complete them. Coming to Mangalore we find nothing that calls for unfavourable comment. This season was the alternate one in which, in the natural order of things there should be a small crop, and it is in excess of that of 1885-87 and only 60 tons behind 1888-89. After a small yield in the previous year, it might have been expected that a large one would result, but judging from Messrs. Alston Low & Co.'s remarks, the order is to be maintained and 1891-92 is to see the big crop.

The worst portion in these statistics is the serious diminution in the exports of native coffee from Tellicherry, which is not in any way compensated by an increase at any other port. Hitherto the seasons have not affected native gardens in the same way as they have done the plantations of Europeans, and this tremendous drop of 12,000 cwt. must be taken as evidence either that a large amount of native coffee has died out, or that leaf-disease has taken a firm hold on the native gardens, and native crops henceforth will be as variable as plantation. Pepper, like native coffee, is almost entirely cultivated in native gardens, although it is attracting the attention of Europeans more and more every year. Tellicherry is *facile princeps* the chief mart of this produce, exporting 33,000 cwt., of which by the way it imported no less than 12,000 cwt. We would here draw the attention of the railway authorities to imports of coffee and pepper into Tellicherry, a port which has no particular facilities either for shipping or warehousing, but merely possesses wealth and enterprise, and if these qualities enable it to import from other sea-coast towns by country craft 36,000 cwt. of produce during a dull slack season such as that of 1890-1891, we can without the least hesitation affirm that if it were connected by railway with the interior it would very shortly work up a trade that would be only second to that of the Presidency town. While most of the towns shipped their pepper to Bombay and other Indian ports Tellicherry supplied the continental mart, France taking 57,500 cwt. through Havre and Marseilles. London, it will be seen, only imported 2,860 cwt. of pepper, for it is a curious fact that while the English taste demands the finest quality of coffee, it prefers the inferior grades of pepper, which the Straits Settlements supply. Out of the 61,700 cwt. of native coffee shipped from Tellicherry, France took 59,000 cwt. Before concluding this hasty review of these interesting statistics, we may mention that the value of the coffee may be set down at 105½ lakhs and the value of the pepper at 30 lakhs.—*Madras Times*, Oct. 6th.

HAUTEVILLE FACTORY.

Abbotsford, Nanuoya, Oct. 12th.

When I wrote about the Carlabook factory the other day, (see page 321) I had not been to Hauteville; and now I must say, without any depreciation of the former, the latter will take a lot to beat. It has been erected under the other (W. B.) Jackson's superin-

tendence; and what money and brains could do, brains and money have done. Imagine first of all half of the river being bodily built up into a watercourse 660 ft. long and protected throughout its length by a rubble bank. All this for a turbine which develops 30 horse-power from a fall of 8 ft.,—the lowest fall in Ceylon, I believe. The building itself is, I should say, 150 ft. by 60 ft., with side pillars of stone, and central uprights of iron, and is asphalted throughout. It has three lofts, and is fitted up with an enormous engine, two Excelsiors, two Brown's rollers, two Victorias, one Davidson's down-draft Sirocco, roll and tea-sifters, and four Blackman's fans. A simple calculation from the driers shows that this factory can easily turn out 1,500,000 lb. of tea annually. On asking Mr. Jackson his opinion, he said he liked Davidson's down-draft Sirocco as well as any he had had to do with. But then he had never seen the Britannia! I must reserve further details for another letter.

TEA MACHINERY ON THE AGRA PATANAS: REMINISCENCES OF THEIR PRISTINE SYLVAN BEAUTY.

The same correspondent who described the equipment of Caribook and the working of the Britannia Drying Machine now tells us of a similar triumph of engineering skill at Hauteville, on "the Agras." The river which rises on the side of the majestic Kirigalpotta and is with its tributaries finally lost in the ocean near Trincomalee, is compelled, at Hauteville, to turn a turbine, and the power thus obtained is used to work a formidable array of rollers and down-draught siroccos and Victoria driers and sifters and cutters. "All on wheels! All on wheels!" as the Turk in Eothen exclaimed. But what a contrast since the time (and it does not seem so very long ago) when, in company with poor L. St. George Carey and our good friend A. H. Thomas, we explored and gave way to poetic raptures over the then virgin beauty of the gem-like patanas, in the then virgin beauty of the gem-like patanas, in a setting of unbroken "forest primeval"; the stream, with its mirror-like pools, where the waters seemed to be

"To their own far off murmurs listening," adorning both forest and grass land as with traceries of now frosted and now polished silver. "Here," said poor Carey, then in the prime of his energies and the flush of his sanguine schemes, "Here" [where Hauteville now shows its cultivated fields and its factory recounding with the whirr of machinery], "here I will have my bungalow, and there," pointing to a long, glassy reach of the river, "there I will have my boat. These lots I must have." We were then meditating "going in" for an Agra lot; but in view of our companion's enthusiastic utterances we felt, as turned out to be the case, that success was hopeless. The Agra lots, of some of the finest of which, distinguished for indescribable sylvan beauty, Mr. Carey became the proprietor, went at prices beyond our modest means. One of Mr. Carey's lots was named St. George and another Hauteville; and as cultivated estates and the scours of busy human labour as well as of labour-saving machinery of the highest order, they have a beauty and interest of their own. But to life's latest hour we are not likely to forget the views on and from the emerald patanas, ere the forests of a thousand generations had been felled, and while their shade provided the mountain stream with conditions for a game at hide-and-seek on which the archaic mountains looked down with solemn complacency. But while recalling reminiscences of the natural beauty of

the Agras and the life and action and hopes now centred on them in connection, with the great tea enterprise, let us not forget the coffee episode which came between; an episode ending in too many cases in broken fortunes and broken hearts. Such vicissitudes are common to human pursuits, but not so common the brave perseverance with which the majority of the planters turned to the retrieval of their fortunes with the now staple tea. Long may it flourish, and may all connected with it have reason for thankfulness in continued prosperity! The tea planter can feel beyond doubt that in supplying the world with his product he is conferring high benefits on his fellow-men, a consolation denied to those who fill the world with alcoholic beverages, fatal to a very considerable proportion of those who drink them and injurious to the bodies and souls of a further large proportion who are able to resist or postpone their fatal tendencies. The mere they are superseded by

"The cups which cheer but not inebriate,"
the better for humanity.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held within the Local Board Room, Nuwara Eliya, on Friday, the 9th day of October 1891, at half past 4 o'clock, (4-30 p.m.) in the afternoon. Present:—Messrs Ciles F. Walker (Chairman Planters' Association of Ceylon), A. W. S. Sackville (Chairman, Maelikiya Association), F. C. Gubbins (Udappussellawa District), W. D. Gibbon (Kandy Committee), A. L. Cross (Kandy Committee), J. H. Starey (Kandy Committee), and A. Philip (Kandy Committee, Secretary, Planters' Association of Ceylon).

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Friday, the 18th day of September 1891, were taken as read and were confirmed.

Resolved that Mr. Gubbins's name be added to the Standing Committee of the "Tea Fund."

Read letter from Mr. Alexander Tait. Read letter from Messrs Walker, Sons, & Co., Limited, enclosing cheque for Rs50 for the "Tea Fund" for current year, recognising the good work the Committee is doing and the fact that all are interested in increasing the consumption of Ceylon Tea.

Read letter from Mr. Hugh B. Roberts. Resolved:— "That it be pointed out to Mr. Roberts that the money expended upon the Tea Kiosk and its fittings does not yet amount to Rs5,000, and that this sum will cover the total cost; that the building is being leased to both the Ceylon Tea Company, Limited, and the Syndicate Boat Company, Limited, with the sanction of Government, and that the total rent amounts to between six per cent and seven per cent upon the sum voted by the Committee, and security has been taken that the basement of the building will not in any way be used to the detriment either of the Kiosk or those using it."

Read letter from Mr. Sholto G. D. Shrine, Chairman, Dikoya Association.

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.—Read letters from Hon. Mr. L. H. Kelly enclosing a communication from His Excellency the Governor stating that the following gentlemen had been asked to form a Committee for the Ceylon representation at the Chicago Exhibition:—Mr. Saunders, Mr. Dawson, Mr. Grinlinton, Mr. Giles F. Walker, Mr. Henry Bois, Mr. Haly, and Dr. Trumen.

Read letter from Mr. A. E. Wright. Resolved:—"That a special fund be started to augment the sum already voted by the Standing Committee of the Tea Fund for furthering the interests of Ceylon Tea at the Chicago Exhibition, and that subscriptions be generally invited for this purpose."

CEYLON TEA IN PARIS, AND THE CORRESPONDENCE WITH COMMITTEE OF LONDON ASSOCIATION.—Resolved:—"That in view of the opinion expressed by the Tea Committee of the Ceylon Association in London in the letter of the 24th July as to Mr. Leugh's position and capabilities the Standing Committee of the Tea Fund being desirous to introduce Ceylon Tea into France will favourably consider any feasible scheme that the London Tea Committee recommends sufficient guarantees being taken that Ceylon interests would not be subordinated to Indian."

ANALYSES OF SAMPLES OF TEA GROWN AT VARIOUS ELEVATIONS.—Resolved:—"That consideration of the matter be postponed."

The Standing Committee of the "Tea Fund" then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

THE NEW TEA DISEASE.—Simultaneous with the publication in our columns yesterday of the paragraph which had appeared in the *Madras Times* concerning the new tea disease which Mr. Montague Barton, late of the Assam Company, had professed to have discovered and to be able to cure, the gentleman arrived in Ceylon by the Goolpara quite unexpectedly from Ooonoor where he is engaged in planting, and he proceeded almost at once to Kalutara to see his brother who is superintendent of Mr. De Souza's estate. Tageriya, Mr. Barton declines at present to speak about either the disease or the cure for it, not having completely satisfied himself yet, but he intends making a few researches in Ceylon and then making known the result of them. He will be in Ceylon probably three weeks. The new disease, whatever it is, he says he first discovered in the low country here, after which he found it again in Assam and then in high-growth tea on the Nilgiris. We may hope to hear more about the matter when Mr. Barton returns from Kalutara.—Local "Times."

THE CEYLON TEA FUND.—From the minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Nuwara Eliya on Friday last, (Oct. 9th) it will be seen that in reply to a letter from Mr. Hugh B. Roberts it was resolved to point out to Mr. Roberts that the money expended upon the Tea Kiosk and its fittings does not yet amount to Rs. 15,000, and that this sum will cover the total cost; that the building is being leased to both the Ceylon Tea Co., Ltd., and the Syndicate Boat Co., Ltd., with the sanction of Government, and that the total rent amounts to between six per cent and seven per cent upon the sum voted by the Committee; and that security has been taken that the basement of the building will not in any way be used to the detriment either of the kiosk or those using it. We hope that this will satisfy Mr. Roberts and other dissentients. The Committee also resolved that a special fund be started to augment the sum already voted by the Standing Committee of the Tea Fund for furthering the interests of Ceylon tea at the Chicago Exhibition, and that subscriptions be generally invited for this purpose. We have no doubt that the appeal will meet with a liberal response. With regard to Ceylon tea in Paris and the correspondence with the Committee of the London Association it was resolved:—"That in view of the opinion expressed by the Tea Committee of the Ceylon Association in London in the letter of the 24th July as to Mr. Lough's position and capabilities the Standing Committee of the Tea Fund being desirous to introduce Ceylon tea into France will favourably consider any feasible scheme that the London Tea Committee recommends, sufficient guarantees being taken that Ceylon interests would not be subordinated to India." On this subject we would call attention to the letter from Mr. Whitham on page 329.

A NEW USE FOR EUCALYPTUS LEAVES.

In the last Reports on the Horticultural Gardens at Lucknow and Saharanpore reference is made to the marked increase in the demand which has arisen for eucalyptus leaves. The publication of the Report of Mr. Kyle, the Locomotive and Carriage Superintendent of the Bengal and North-Western Railway, and the remarks made thereon in last year's report on the Gardens regarding the efficacy of the extract from eucalyptus leaves in removing incrustation in boilers of locomotive engines, has attracted widespread attention, and led to numerous enquiries for further information on the subject and also to demands for supplies of leaves. Nearly all the orders for the latter were satisfied, and 78 maunds were sent out during the year. A demand has also arisen for seeds and plants, but as result of applications to botanical and other public gardens in India and Australia for seed was that only sufficient for the requirements of the Lucknow Gardens was obtained, though hopes are entertained of a larger supply being received from Australia. Leaves were forwarded to three Locomotive Superintendents in the north of India, and also to the North-West Seap Works at Meerut, and the action of the infusion of eucalyptus was briefly reported on by the District Locomotive Superintendent of the North-Western, and the Ouda and Rohilcund Railways. The former says the process he adopted to obtain the infusion was to boil the leaves in water twice or three times, and then draw off the liquid, which had then become of a dark peat colour. When an engine has run three or four hundred miles it is washed out and in filling up the boiler again ten gallons of the eucalyptus infusion is added every second day. This process he has tried for six or eight months and the result he considers fairly satisfactory. The fluid is an assistance in loosening the scale which accumulates on the boiler tubes and stays; but he is personally in favour of kerosine oil, as, though more expensive than the eucalyptus infusion, it is more rapid in its action. The District Superintendent of the Ouda and Rohilcund Railway at Chandansi says the result of the experiments with the fluid was most encouraging. The Railway Companies appear to have favourably viewed the results of the experiments, for they have indented pretty heavily on the Lucknow and Saharanpore Garden authorities for seeds and plants for sowing in their own ground. The eucalyptus grows most luxuriantly on the Nilgiris, and a profitable trade might be carried on in the sale of the leaves of this tree. The oil which is extracted from the leaves is of benefit to those troubled with chronic thickening of the mucous membrane of the fauces and throat; with intermittent fever, ague, bronchial or phthisical affections, ulcerated throats, migraine or other forms of neuralgia, asthma, bronchitis, etc.—*Madras Mail*.

TEA GOOD FOR DIGESTION.—Tea is persistently condemned as a pernicious herb by the great body of our physicians, but quite another opinion has been expressed by Professor German Sée, a very able hygienic physiologist. The Professor declares tea to be the best digestive, and the surest means of maintaining the intellectual energy. He recommends, however, that it should be used weak at a moderately high temperature, and in the quantity of half a litre or a little more at a time.—*Scotsman*, Sept. 19.

DELIVERIES OF CEYLON AND INDIAN TEAS.—The figures from 1st January to 31st August show Ceylon as rapidly gaining on Indian. In the eight months of 1887, Ceylon showed only 6,203,000 lb. to 51,895 Indian, Ceylon being only one-ninth of the Indian. By 1890, the deliveries of Indian culminated with 66,591,000 lb., Ceylon in proportion being 24,116,000 or more than one-third. In 1891 Indian has gone down to 62,814,000 lb. while Ceylon has risen to 33,798,000, or considerably more than equal to half the quantity of Indian.

Correspondence.

To the Editor.

THE BRITISH NORTH BORNEO CO. AND THE
BRITISH BORNEO CO., LD.

Kew, Bogawantalawa, Sept. 23rd.

DEAR SIR,—Your editorial paragraph in your issue of the 21st of the British North Borneo Co. is calculated to lead your readers to believe that there is something wrong with the Company which administers the Government of British North Borneo. The Company, whose proceedings you criticize, is a private one called the British Borneo Co., Limited, and has nothing whatever to do with the governing Company, of which Sir Rutherford Alcock is Chairman, and in which Mr. Henry Walker holds the post of Commissioner of Lands.—Yours truly,
W. D. GIBBON,
Special Representative, British North Borneo Co.

[We are glad to find that we fell into an error (a very natural one) in confusing two companies with such similar titles; and we are additionally glad to learn that it is not the big governing company that is in difficulties. The latter company ought to absorb the smaller body in order to prevent confusion.—Ed. T. A.]

THE LONDON AND LOCAL MARKET
FOR TEA.

Central Province, Sept. 26th.

DEAR SIR,—“Superintendent,” in his letter of the 21st, omits to include his Colombo agent's and Broker's commissions and sale charges, which will amount to $\frac{1}{2}$ cent, as against the $\frac{1}{4}$ cent for shipment by ordinary shipping agent. Why not fix the rate for exchange on the one parcel sent home instead of giving us the rate for the year? Why also fix twopence a lb. London charges! $1\frac{1}{2}$ pence per lb. is a stiff price even to pay for London charges on such carefully bulked and packed teas as “Superintendent” has the handling of. Let “Superintendent” bear in mind that out of say 8,000,000 lb. tea sold locally only about 3,000,000 lb. have been sent to other ports than London, so does he expect the Colombo buyers to look for a less profit than a penny or $\frac{5}{8}$ cents per lb.?—Yours truly, ONE WHO HAS TRIED BOTH.

COFFEE IN NORTH BORNEO.

Kandy, Sept. 29th.

DEAR SIR,—The following extracts from a letter dated North Borneo, 29th August, and referring to coffee, may interest your readers.—Yours faithfully,
W. D. GIBBON.

The young clearings planted (in coffee) December 1889 and January 1890 are now bearing crop which will be ripe in say March 1892, and then the picking season will be twice a year, in quantity; and in small quantities nearly every month. The trees are from 4 to 7 feet in height or say average 4 feet 9 in to 5 feet. The four year old coffee is bearing heavily and looking well.

The land chosen for our new clearing (100 acres) is close to the bay and runs up to 1,000 feet in a long easy slope—the water supply is very good and a launch can go up to the village.

PALMIRAS AND COCONUTS.

DEAR SIR,—I should feel ever grateful if you would kindly give me the following advice:—On one of the estates under my management, there are, I should think, nearly as many waddies, or young palmiras, as there are coconut trees. My intentions were to cut all these waddies down and manure the estate with same. The leaves I should put round the trees dug in, but the stem or body of the tree can I manure with, by digging trenches and putting them in, and how far would I have to put them in the soil? The trench would be dug between the lines of the coconut trees; the waddies put in with other rubbish etc., and filled up again. Do you think this would be beneficial to the estate or would you advise me to burn the stem and apply ashes round the tree.

For any advice as regards this given me I should feel greatly obliged, as I think the sooner the waddies are rooted out and cleared from the estate the better, as the amount of young plants are increasing year by year.

It will no doubt be a very expensive process cutting down all the trees. Do you think it is advisable for me to cut the top off and let the tree rot? That will be beneficial as the roots of the coconut tree will suck all the substance from the waddies. The only thing I am afraid, of is beetle attacking the waddie when it is so far decomposed. When the top or head is cut out the tree rots away in a few weeks and the juice is abundant inside the tree, which would, I should think, benefit the coconut.

Awaiting your reply, I remain, yours very faithfully,
PLANTER, PALLAI, N.P.

THE HISTORY OF THE LOUGH CASE
AS DEALT WITH BY THE CEYLON
TEA FUND COMMITTEE.

Aranayaka, Oct. 10.

SIR,—I have been to some extent the medium of a certain amount of friction between the Ceylon Tea Fund Committee and the Tea Committee of the London Association: as my name has been brought into the matter both by your London correspondent and that of the “Times of Ceylon”; and as the former in his letter of Sept. 18th states the general feeling to be that the action of the Ceylon Tea Fund Committee was taken “on insufficient and unsupported representations,” I think it only fair to that Committee to make public, with your leave, a history of the affair as far as I am concerned in it.

Mr. A. S. Hutchison wrote to me on April 10th and at the same time sent out a parcel of sundries which he asked me “to kindly place before the Tea Fund Committee when Mr. Lough's proposition comes forward.” As he addressed me “Dear Sir” and wrote of absolutely nothing but this one matter, it did not occur to me for an instant to look upon his letter as private, and indeed it is not easy to imagine how Mr. Hutchison's object could have been attained by my treating his communication as one intended for my eye alone. So as I am not and never have been a member of the Tea Fund Committee, I placed the matter with one who is; and when I tell you his name (as I do privately) you will agree with me that it could scarcely have been in abler or more discreet hands. I suppose he did at the meeting what I should have done myself, and either read the letter or handed it round for perusal. At any rate I am quite sure he did not say: “Here is a letter which, taken in connection with the sun's rays I place on the table, contains very ample reasons why you should not carry out the recommendation of the London Tea Committee,

but I am unable to divulge the writer's name or to tell you what he says"; for this would have been wasting the time of the meeting.

I quite agree that the letter was not intended for publication; but it has not been published, and has only been seen by or read to the men who were asked to give a verdict on the evidence contained in the letter. This verdict seems to have been precisely the one asked for and expected by Mr. Hutchison, but he seems to have been rendered nervous by the very measure of success which he had achieved, even as we now see our Tea Fund Committee alarmed at having secured the conviction of those prosecuted for fraudulent description, and to have tried to soften things down a bit, but whether he (unconsciously) encouraged in any way or not your London correspondent's belief in the private nature of his letter to me I cannot say. Apart from this question, which I hope these lines will settle, the matter seems very simple. The statements on which the Tea Fund Committee acted were either correct (and I myself firmly believe they were), in which case that body was fully justified in the course taken; or they were incorrect, in which case—well I'll let the London Association settle this, and remain,—yours obediently, HENRY WHITHAM.

COFFEE AND PEPPER EXPORT FROM THE WEST COAST OF INDIA.

Tellicherry, Oct. 2nd.

DEAR SIR,—Along with this we have the pleasure to hand you our annual statement of exports of coffee and pepper from the West Coast for the year ending 30th June 1891.

COFFEE.—Our gloomy anticipations of the past crop were fully confirmed by results, the export showing a decrease of 22,585 cwt. Plantation coffee and 36,459 cwt. Native coffee or 59,044 cwt. in all as compared to season 1888-89 when the smallest crop was shipped from the West Coast since we commenced to keep these statistics in 1879-80; so the past season is a record one in its most disappointing sense. The largest quantity of plantation coffee was shipped from the northern port of Mangalore which is the outlet on the coast of Mysore and North Coorg crops, and as usual the bulk of the native coffee was attracted to Tellicherry, but the exports from these two ports cannot be taken as a fair criterion of the actual crops of coffee from Mysore and Coorg, as a portion cured at Bangalore and Hunsur is eventually shipped from Madras. The Calicut and Boypore exports include the crops from the Neilgherries cured at Coimbatore. Fortunately good prices prevailed in all markets.

We are glad to be able to report that prospects of coming crop are much more encouraging especially in the northern districts of Mysore and Coorg where owing to shade, leaf disease is not virulent. A considerable quantity of land is being opened up in Mysore and seeing that nearly all the older properties in that district which for some years past have been undergoing a state of transition from the old "Chick" plant to that of the "Coorg" type are almost entirely planted up with the latter, we have every right to expect bigger crops from that district at least.

PEPPER.—Although the quantity shipped of this article from Tellicherry was considerable, total exports from coast were less than last year, and prices are comparatively speaking so low, that it is doubtful if the increased acreage of cultivation which has been a characteristic of the past few years will be maintained.

It is hard to obtain reliable information in regard to the crop now on the vines, but from what we can gather it will be an average one.—Yours faithfully,

p. pro. ALSTON, LOW & Co.,

THE PROSPECTS OF CEYLON TEA IN AUSTRIA.

All the way up from Brindisi to Venice, but more especially from Venice to Karlsbad, we have, without intruding the subject unpleasantly, preached the merits and 'economy' of Ceylon tea! Without venturing to anticipate great results, we may at least say that we have thoroughly interested a large number of persons, among our fellow-travellers, and still more residents in Vienna, Prague and among the floating population of Karlsbad, in the subject. "The planters of Ceylon want everybody in Austria to drink Ceylon tea" was usually the semi-jocular remark with which interesting conversations closed. "Oh," said a Styrian vineyard proprietor, one of a group of eager listeners and questioners on the Semmering, "that is what we desire and have not yet managed for our wines."

To several tea-dealers we have ventured to give the address of Colombo firms, and more particularly of that (Messrs. Volkart Bros.) representing the Austro-Hungarian Consulate and Lloyds, when the question was asked where they could get samples and prices, or a certain quantity of the tea on trial. This was the case with the principal tea importer in Graz (the capital of Styria) who, fortunately, travelled with us to the neighborhood of Vienna. He expressed himself as especially interested in all we told him, and as determined to make a trial of the tea among his customers.

IN VIENNA.

In Vienna we devoted a day to a round of visits among the principal tea importers and dealers. We found their addresses readily enough in the City Directory. In the case of the town dealers, even those doing business on an extensive scale, the curious combination holds good, which prevails all over the Continent, of "Tea and Rum" as the two articles to be imported, distributed and sold together. The fact is that, save in Russia, tea is regarded more or less as a medicine—so we found it in Central France procurable only at the Apothecaries,—and although it is not so in Paris or Vienna, yet the addition of some rum is evidently considered needful to render the tea palatable or to counteract its effects on the nerves! At any rate, we have everywhere to face in business here—wholesale and retail—the combination which will be so shocking to teetotallers, of "Thee und Rnm." Our first visit was a most pleasant one and gave us a pre-taste of the courtesy and attention which awaited us everywhere in Vienna. Very soon, several members of the firm and staff were listening and questioning on the subject, interested especially in the news of the vast expansion of the Ceylon tea production, and, alas! in the falling off in coffee. By-and-bye, a partner turned up who spoke English well and he took us the round of their stock of coffee which included a considerable number of barrels of Ceylon finest—Dimbula, Udapussellawa and Haputale marks. I noted especially "Meeriabedde" and they were interested that I should know the very plantations from which their coffee came. Austria takes a very large quantity of the very best coffee in the world, and let us trust that the day is not far distant when she may require an appreciable stock of the very best tea. Our friends directed us for our second visit to the firm who, they said, did more in importing and distributing tea than any other in Vienna. This house (I give no names all through) we found did a large if not all its business through

Mincing Lane; and we were introduced to the Austrian gentleman who acted as their agent or buyer in London, and who was known familiarly to them in Vienna as "Robertson," because as I inferred he bought through the well-known Colombo house of the name. That must refer chiefly to coffee, for though Ceylon tea was not unknown, there was not much in stock, nor did it seem in such favour as Indian tea, their stock of which included some Darjiling. These teas were, however, for blending, and we could not here get much encouragement to the hope that Ceylon tea would soon take its place, on its own merits and be drunk pure in considerable quantities. "A good article will make its way by degrees, but there is no use trying to force it by new plans and new ways" was the sum of the opinions expressed by the chief tea importer here, who is clearly a thorough conservative, as most merchants with a sound, well-established and prosperous business are inclined to be. We, however, instanced what had happened in the United Kingdom, in Australia, and what Ceylon planters were trying to do in America and Russia, by new and revolutionary means; and we parted with the assurance that they would probably get an increasing quantity of Ceylon tea, but for blending purposes rather than for distributing by itself, we inferred.

The third firm on whom we called, though in a smaller way, evidently did an extensive distributing business in tea and rum, and the managing partner was the most interested yet, in all my interpreter had to tell about Ceylon tea. He had heard and read somewhat about it, but as yet had bought none. He was much more of our opinion that so good and comparatively cheap an article might well be brought before the Austrian public by every possible means, by advertising even, distributing information in pamphlet form, opening a Ceylon Restaurant or Retail Store, &c. As regards the first, he instanced very appositely, the case of "VAN HOUTEN'S COCOA," which, as we had noticed, is largely placarded all over Vienna, and is perhaps the only tropical product so advertised and no doubt with profitable results. There can be no doubt that if CEYLON TEA were similarly advertised, the attention of the people could not fail to be drawn to it, and [if the needful information and supply were simultaneously made readily available, enquiry and demand would follow. [I found the readier access to the opinions of the different merchants being able to announce that I was not a tea dealer or planter, but a journalist interested in the welfare of Ceylon's chief industry.]

Our fourth visit was to a dealer of a lower class—a respectable family grocer in a big way, but who kept his teas for sale in very large glass-stoppered bottles and who retailed China and blended teas at from 5s to 8s the lb., the demand being for small quantities. He did not think much of a sample of Ceylon high-grown we had with us; said it was too much of a hay flavour, and that the decoction would be far too bitter and strong to suit the Austrian taste.

Far more encouraging was the opinion of a dealer in a more fashionable street, who might be called an Austro-American, he having been several years in Chicago before opening in Vienna. He knew a little about Ceylon tea, was much interested in our sample, had indeed sold some tea got from London, as "Ceylon," very freely among his customers and he would certainly go in for more, and try if possible to make a business with Colombo direct, though his requirements would be small to begin with. He had introduced Californian "preserved fruits" into Vienna, and it was his intention to have a stand at the approaching Exhibition with Food-

Products; but he was afraid he could not get a supply of Ceylon Tea in time to exhibit. He approved very heartily of Ceylon planters advertising; distributing samples to hotels, restaurants with information, or of opening a Café at which good Ceylon tea properly prepared could be drunk.

On this latter subject we had a good deal of conversation with the Commercial Secretary to the Handels (Trades) formerly Oriental Museum, who promised to communicate with Baron von Scala and let us know the result at Karlsbad. As already mentioned, this institution is now managed after the fashion of a Limited Company, and is associated with a Trades or Mercantile Association, a large number of offices occupied by business men being let on the lower floors of the extensive block of buildings in which the Museum is located. The idea was suggested as to whether a Restaurant might not be opened in this same block, having for its main object the distribution of pure Ceylon tea, by drinking or selling in packets, and that so located it could not fail to catch the attention of influential business men whose good opinion, if obtained, could not fail to be very valuable. Although not empowered by the Ceylon Tea Fund, or instructed by them, I thought there could be no harm in getting information as I was on the spot, which might, or might not, be utilised in the future. Then again, I thought it would be well to have among the Ceylon Exhibits at the Museum, samples of our different teas which if made up in small boxes with, say, glass tops, could be seen in good order for a long time to come. On both these subjects, I have been favoured with an official reply from Baron von Scala which I hope the Committees of the Ceylon Tea Fund will not take amiss to receive through your columns. Had I been empowered to enquire for them, I should, of course, have communicated direct. Baron von Scala's letter is as follows:—

Vienna, 29th August.

John Ferguson, Esq.,

Posts Restanto, Karlsbad.

Dear Sir,—In reply to the proposal you made with regard to exhibiting a Sample Collection of Ceylon Tea at the Museum, we shall be very glad to receive the samples.

As to your second proposal to promote the sale of Ceylon tea in Vienna, we offer you the following arrangements.

We should open a separate room at the Museum for the sale of Ceylon teas and a tea bar, where Ceylon tea may be given away to visitors of the Museum on certain days. The cost of installation would be about £10 and other expenses, including wages of two bar-maids etc., would come to about £10 a month, of course not including value of the tea and other Ceylon produce to be given away. Freight to Vienna and customs duty would also be at your charge.

Should you wish to report this to the Ceylon Tea Planters' Association, we shall be pleased to have your earliest advice.

Meanwhile we remain, dear sir, yours faithfully,
The Directors of the I. R. Austrian Commercial Museum,
A. V. SCALA.

I am not sure from the above whether the idea of having a restaurant after the ordinary fashion, with Ceylon tea as a main feature, was considered feasible. What seems to be contemplated above is a room for the retail sale of Ceylon teas in packets, and a bar where cups of tea could be given gratis to visitors, so as to induce a sale; or it may be that a salo in the cup even is contemplated to other than visitors and on certain days. It is, however, not worth while enquiring further at this stage; for I am not sanguine that the Tea Fund Committee will care to go in for

a "Ceylon-Vienna Tea Fund Bar" just at present, and yet the cost for one year's experiment in this way—£130 in all—would seem comparatively moderate apart from the cost of the tea supplied (with duty and freight paid) but which ought to be nearly covered by the proceeds of sales?

But whether the Tea Fund Committee take up this proposal or not (communicating if they do with Baron von Scala and the directors direct, or with me if they wish me to move further), I do trust that they will not lose sight of the advantage of sending nicely-made up samples with average prices noted, of the different kinds of Ceylon tea for exhibition in the museums. Baron von Scala and his directors, indeed, deserve a vote of thanks for the readiness and courtesy they have shown in considering and agreeing to proposals intended to benefit Ceylon planters, by promoting the sale of their teas in Vienna, and I hope this will not be overlooked.

WHAT HAS BEEN DONE FOR CEYLON TEA IN VIENNA.

But it was not till after I got to Karlsbad that I recalled the fact that the Ceylon Tea Fund, through Mr. Charles Osswald, a Swiss merchant, had already done something to promote the sale of our teas in Vienna; and finding the address of the gentleman whom Mr. Osswald had appointed agent, I thought it well to write to him enquiring as to progress, and mentioning what we had done by way of interviewing in Vienna, asking his opinion too about advertising, disseminating information and a café. I was also anxious to know if he, or anyone else, was doing anything for tea in the Food Products Exhibition opened after I had left Vienna. The result was a very long letter in German (the language used for my inquiries) some parts of which the writer does not want published for good reasons; but the substance of his report may be given as follows for information of those interested in Ceylon and specially of the Tea Fund Committee:—

Vienna, 6th Sept. 1897.

Honored Sir,—In receipt of yours of the 2nd inst., I do myself the honor to reply that the Food Exhibition was already opened on the 1st, and is to remain open till 1st December or January, also that it is in the saloons of Garden-Errections' Company on the "STÄDENING."

I have seen the Exhibition and send you now by post the catalogue of the Exhibits (free). As the whole Exhibition is included within 5 large rooms and their galleries, you will understand that, comparatively speaking, it is not a large one. It is visited by about 2,000 persons daily and on Sundays by perhaps five times that number.

Tea appears to be only exhibited by three firms and by them only as a secondary article. Cognac and rum are brought by the same firms well to the front and they would seem to consider these far more important than tea.

In the "Tasters'" or Refreshment Room where various Exhibitors can hire stalls for the sale and tasting of their goods, only wine, cognac, liqueurs, &c., are sold, but no tea. The spaces for exhibits are by no means all occupied, and there is still plenty of room. The better opportunity for the exhibition of Ceylon Tea would have been last year. Now similar exhibitions of tea occur, and if only I had the necessary support that is the money (for alone I cannot undertake anything), I might advance the Ceylon tea interest in them.

With regard to the distribution of Ceylon Tea, I must tell you this: I myself am no merchant, but so employed that I can devote my time from 8 in the afternoon till 9 next morning exclusively to the Tea business. I am further able, if specially necessary, to get the time from 9 to 3.

My brother-in-law, Mr. C. Osswald, in the winter of 1896 sent me the first sample chest of Ceylon tea, upon which, in August, three farther chests followed; and after the business had got into order, I had a

relative formally registered in January this year, who thus can pay the duty &c., as well as any merchant. I, however, am still the soul of the business.

A short outline of our activities will show you whether, in view of the fact that Ceylon Tea is a foreign and unknown article as compared with Russian and must therefore first win for itself the general confidence, the quantity which has so far been supplied by my brother-in-law may not be regarded as satisfactory.

		lb.	
In January 1890	1st Despatch	50	about
August "	2nd "	150	"
December "	3rd "	400	"
Beginning January 1891	4th "	1,600	"
July middle	5th "	1,700	"
Now being sent	6th "	600	"

lb. 4,400

To these I hope many more despatches will follow with increasing rapidity. If you look at these figures and consider that only an outsider and not a regular dealer in so comparatively short a time has succeeded so well, I think you will acknowledge that it is not necessary to be a regular merchant in order to be a successful Agent.

But as far as the trade connections are concerned these will also in course of time arise, especially as I have only to do with one branch, and can therefore devote more attention to that. Another advantage on my side which the dealer has not is this: that I am independent and there is no need for mutual favours as is the case between members of one fraternity or profession. I have arranged with a number of persons to supply an unlimited number of pound packets which will be sold to others, and as they and their friends find out the excellence of the tea, the sale will greatly increase. In one department of Government where there are some 15,000 employes, besides day labourers; so it will take some time before I can get the article known to them all. I have farther taken steps and attained results through personal representations in various official and public offices, with different Unions, Banks and Insurance Societies, finally with a large business house. All this work has cost me at least 100 guildens from first to last. It will cost still more yet to introduce the tea to separate corporations to make the acquaintance of a great many more employes, and all the expenses I must meet, including that of numberless samples. One Union here has very kindly allowed me the use of their paper free for the insertion of articles and advertisements; also my circulars with description of tea and directions for its preparation can be sent with that paper while the article is recommended by the paper itself in separate paragraphs of the journal. Since June this year I have been elected member of the Central Committee of this Union and at their meetings several times in a month, I meet representatives from different parts of Austria. If I wish to put my advertisements in both papers it will cost 20 g. a month, a round sum for postage. If I had to send it separately the postage would be ½ kr. per piece, but these Unions will do it free, only Government make this postage charge. But who is to pay all this? not I—as I give the tea very cheaply. And only to spread it can I venture to do so, and for the same reason my brother-in-law cannot undertake the expenses.

When I have got a great number of customers on my side, for which I may want about 2 years, then I will come forward with my advertisements. After a greater number of officials and acquaintances have become accustomed to the foreign Ceylon tea, then will no tea dealer or "Deliatessen" dealer have anything to say against it; but then will the time come when these will have to provide themselves with a supply of Ceylon tea.

I could, dear sir, also tell you in greater detail in what offices, &c., I have already got a footing, but this would be of no interest to you. But I will tell you that my supplies of tea have hitherto gone to Vienna, Lower Austria, Bohemia, Moravia, Galicia, Hungary, Upper Austria, Tyrol and Vorarlberg, also

that some business houses through other channels have been supplied. In the town of Meran (Tyrol) is a mineral water cure; one confectioner has taken it up. I should like also to have Karlsbad, but I know no one there.

That I have enough to do to get tea introduced on all sides, even though in small quantities, you will acknowledge. Besides the employes already referred to (perhaps 15,000) there are also others perhaps 20,000 more added to these, professors, teachers, doctors, ministers of religion, friends of these employes, and you will see how many I may say. If one considers that the cost of sending out circulars that has to be met every month is undertaken by one single person, one will come to the conclusion that this cannot be just or right: one will much rather incline to the opinion that insofar as the business opens up and promises to the Tea Planters' Union of Ceylon a rich field in Australia, the latter should render the material help needed.

If in consideration of all the trouble and work I have had and efforts put forth, which in many directions have proved fruitless and useless, the members of the Tea Fund Committee would now consider whether they could allow me a fixed sum half-yearly, I am sure they would reap 10 or 100 fold profits thereby.

Say if they could give 600 to 800 guildens equal to £50 to £60 a year, I should then devote myself with all my strength and energy to the matter and should be able to show "colossal" success such as already has crowned my efforts in another branch of work. I beg you sir, to consider the matter and to give the Tea Planters' Committee your opinion as quickly as possible that they may soon arrive at a decision. — I am &c., ———

I am not at liberty to publish this gentleman's name yet: he must be known for the present as the relative of Mr. Osswald; but it can be judged that he is certainly taking a special interest in Ceylon tea, its distribution and sale; and although only "the day of small things" is indicated by the 4,000 lb. he mentions; yet I am sure the Tea Fund Committee will agree that this Vienna resident is deserving of some special support on his own account. A free grant of tea—say 1,000 lb.—would probably do more to encourage him than a money payment and I have asked him in reply to say whose name should be given to the Committee, if his own cannot be used for the present; or whether Mr. Osswald should still be the medium. As regards Austria generally, however, the field is so wide and the people are so well disposed, that I do not think attention should be confined to one agent. In Vienna alone, with its enormous population, there is encouragement to work in a much more public way for Ceylon tea. I am hopeful that the regular tea dealers may at once be stirred up to import the new tea—several promised, as the result of our interviewing, to send for samples and prices; others to try a small quantity for their customers at once. I think the Exhibition of Samples at the R. I. Austrian Commercial Museum under the care of Baron von Seala and his Secretary Mr. Röhn, could not fail to draw the attention of business men and other visitors; while the question of a Sales Room and Ceylon Tea Bar for free distribution (in the cup), as a temporary measure, may or may not be considered worthy of undertaking. In any case, after the samples are sent to the Commercial Museum, and there is time for dealers to provide themselves as promised, I think Vienna is quite ready to be placarded (à la "Van Houten's Cocoa") with "Buy" or "Drink the new tea"—"Pure Ceylon Tea," or some such combination—perhaps the last, "ECSTER CEYLON TEA" would answer as well as any. This placarding would not cost much I fancy, and could be arranged for through Mr. Osswald, or his relative,

Premising that, so far as I can learn, the Austrian Customs duty on tea is equivalent to 10d a lb. or at present exchange about half a gulden or florin which contains 100 kreutzers, the following price list of a wholesale tea-importing Vienna house will be of interest. The price is given per kilogramme of 2½ lb. on which the duty so far as I can make out, would be equal to 1 florin and 10 kreutzers, which sum should be deducted from the prices in each case, the florin being counted equal to 1s 7½d to 1s 8d each. The price-list then is as follows (the only other two articles imported and sold by this firm being "Rum" and "Cognac")

	THEE.	Pr. Kilo	fl. kr.
(Customs Duty paid about 1s 10d kilo or 10d a lb.)			
Nr.	0 Bruch-Thee (Broken tea equal to 1s 8d a lb.)	..	2 20
"	1 " fein (fine)	..	2 80
"	2 Moulng-Congo	2 80
"	3 " "	3 10
"	4 " "	3 60
"	5 " "	4 50
"	6 Pakling-Congo	6 50
"	7 Kaysow-	5 50
"	8 " "	8 —
"	9 Khluck	9 —
"	10 Ningshow	10 —
"	11 Souchong	3 30
"	12 " "	4 —
"	13 " "	5 —
"	14 Mandarin	8 —
"	15 Caravanen (Caravan tea)	9 50
"	16 " feinst (finest, equal 8s a lb. without duty)	..	11 50
"	17 Peccothee (Pekoe tea, 1s a lb.)	..	7 —
"	18 " " (equal to 8s a lb.)	..	9 —
"	19 " " (equal to 8s a lb.)	..	10 50
"	20 Peccoblütthe (Pekoe blossom)	..	12 50
"	21 Caravanen-Peccoblütthe (Caravan Pekoe blossom 12s a lb.)	..	15 50
"	22 Wirtchachts-Melange, schwarz (Hotels' mixture, black)	..	4 30
"	23 Monopol-Melange, schwarz	6 —
"	24 Feinste Melange, schwarz (finest mixture, black)	..	6 80
"	25 Kaiser- .. gebümt (flowery)	7 —
"	26 Kaiser-Melange, gebümt, feinst (Imperial mixture, flowery, finest)	..	8 50
"	27 Moskauer Melange, gebümt (mixture, flowery)	..	10 —
"	28 Caravanen " schwarz (black)	..	11 —
"	29 " " gebümt (flowery)	..	12 50

It will be observed that the "Pecco-thee" (Pekoe) ranges from 5s to 8s a lb., inclusive of 10d a lb. duty. Now the finest Ceylon "Broken Pekoe" could, I suppose, be laid down at Trieste for a gulden, say 1s 8d a lb.; or with duty 2s 6d, so that the profits to be made on pure Ceylon tea, if only a demand were created, are very large in Austria. For, let it be remembered that the above are wholesale prices. Retail tea is seldom sold beyond quarter lb. packets and these probably range from one gulden (1s 8d) upwards, if indeed "Pekoes" are used save for blending.

Before leaving Tea in Vienna, I will give a list of the exhibits I find in the Catalogue of interest to Ceylon planters. They are, translated, as follows:—

CLASS VI., SPICES, SUGAR AND GROCERIES.

- 55. Cacao manufactory of C. J. Van Houten & Zoon, Weesp, (Holland). Van Houten's Cocoa, 34 Diplomas and Medals.
- 56. Collective Exhibition of sugar, coffee and tea.
- 58. Franek, Heinrich, Sons' private factory, Linz. Coffee surrogate (additions), chicory and malt fabrications, 25 Medals and Diplomas.
- 59. Gottlieb, E., Chinese Tea Depot, Krakaw.
- 61. Haecker & Meissner. Coffee Import, Coffee Peeling Establishment, Trieste. Coffee samples from all the coffee-producing countries of the world.
- 66. Kathreiner's successor, Munich, Bavaria. Malt Coffee.
- 70. Mendl Heidrick & Co., Importers of Tea, Rum and Cognac, 1, Schottentring, Vienna. Tea speciality, legally protected labels on packets for retail sale at 10, 18 and 35 kreutzer (10kr.=2d).
- 72. Perloff Wessely & Sons, Court Purveyors, 1 Kaertnerring 15, founded 1787. Caravan Tea, 4 medals.

73. Pischinger, L., & Son, Chocolate Manufactory, Vienna, VI. Stieggasse 8 and 10. Speciality Pischinger Chocolate Extracts.

74. Pemm, Josef, Raab-Ujvarcos, Raacuta, 46 Art Coffee.

78. Sobtrick, Franz, Chocolate Manufactory. Rati-bor, Broslan. Cacao in lump, Chocolate packets in larger and smaller blocks, powder loose and in packets, Chocolate Sweetmeats, instructive Exhibition of the different stages in the preparation of the cacao from the raw bean upwards. 3 Medals.

79. Stellwerck Bros., Imperial, &c. Chocolate Manu-factory, Cologne on the Rhine. Stollwerck's "Heart" Cacao, Chocolate in tablets, Chocolate fancy objects.

81. Tauber, Josef, Id., Wien, Sonmering. Coffee "Surrogate" (mixture), coffee and ground spices pre-paration. Diplomas.

82. Vreclkor-Coumes, Daniel, Bayon, Meurthe u' Moselle, France. Chicory and Acorn (Eicheln) Coffee.

83. Weiss, Julius, First Vienna Coffee Extract Manufactory, I. Geteide Market 14. Coffee Extract and Coffee Cream in bottles.

CEYLON TEA IN BOHEMIA.

The largest tea importer in Prague, the capital of Bohemia and a town of over 200,000 people, is Mr. Wilhem Stanek, Wradislaw Gasse, and who, I fancy, had the Russian Tea Agency referred to in Ferdinand Strasse, where I see his office was formerly held. Mr. John Fraser of Aberdeen estate had referred me to the Rev. Dr. Pirie for all information and he again introduced me to Mr. Stanek, whom I found a very enterprising man; he had commenced life, I think, as travelling agent for a Paris house, and in that capacity had visited the Far East. Mr. Stanek evidently imports large quantities of tea; but almost all "China", the common kinds from Hamburg and the "Ceylon" teas from Russia. Though I did not question Mr. Stanek on the subject, I rather think Mr. Fraser had experimented through him with a consignment of Ceylon tea, without profitable results to the Ceylon planter. This is strange, for at retail shops where we enquired, the commonest China could not be bought under 4s to 6s per lb. But Mr. Stanek repeated what some Vienna large tea dealers said, that for "Ceylon tea there was no taste—it was little thought of." One piece of information I got here seems to throw light on difficulties in the way of a tea trade through Trieste apart from the heavy Customs duty. Questioned as to why he, an Austrian merchant, got his China tea through Hamburg, rather than through Trieste, the one great port of the Empire and the one so much nearer the Far East, Mr. Stanek mentioned that the charges for "handling"—I infer for landing, clearing at the Customs and despatching—were very much heavier at Trieste. I fear too that there may be difficulties through corruption of public officers there: not long ago there was a great disturbance about the discovery that certain officers had to be regularly fed by large Vienna importing houses (dealers in general goods), and it was supposed that the latter had been getting their imports passed for less than the proper Customs duty; but on examination it was found that the fees, gifts or bribes, were simply to enable the firms to get their imports passed promptly at the proper and full duties—an additional levy on trade in fact. Whether this be the case or not, I think it is scandalous to the Austrian authorities, that any of their merchants even in Bohemia should prefer doing business through Hamburg, rather than Trieste for Asiatic products; and I cannot understand how the Directors of the Austro-Hungarian Lloyd's S. N. Co. have not seen this put right long ago. I have thought it well therefore to address a letter on the subject (and referring as well to the heavy Customs duty on tea and to the subject of Ceylon

tea generally at some length) to the Editor of the Vienna "Nene Freie Presse." The letter has just gone, and I will send you a copy by next mail.

I did my best to interest Mr. Stanek of Prague in Ceylon tea, pointing out to him how it was bound to become the great tea of the future for consumption, even on the Continent of Europe. His business is a very extensive one, and among his staff I found a negro assistant who seemed to have the faculty of picking up readily every language of the Continent, he having already the command of some half-dozen.

So far as the retail and use of tea in Vienna and Prague are concerned, however, one might well despair of making any impression on the taste of the Austrian people in respect of tea-drinking. Tea, unlike coffee, is regarded either as a luxury rarely to be indulged in, or as medicine to be taken only occasionally; and we might suppose it impossible to effect a change were it not for what Mr. Oswald's friend has told us of the distribution of his "pound packet" and still more from what I have seen of

TEA-DRINKING IN KARLSBAD.

Just as the "afternoon teas" which have of late years become fashionable in Paris, may gradually lead a large proportion of the French people to appreciate and use tea freely as a refreshing beverage, so may we have very great confidence that the universal custom of drinking tea at this, the most popular of continental Spas, may gradually spread a taste for the infusion not only among Austrians (including those of German, Magyar, Czech, Slavonic race) but Germans, who of course make up between them the larger proportion of visitors. The difficulty elsewhere on the Continent is to get anyone to look at, much less drink, tea. Here at Karlsbad from April till September at scores if not hundreds of cafés, restaurants and hotels, the cry every morning between 8 and 9 o'clock from visitors who number altogether 35,000, is for "Lin" or "Zwei" Thee, by the individual, or couple! And considering that only a very ordinary "China" or "Melange" (Blend) is used, it is wonderful how drinkable a cup of tea one gets. The proper infusion of tea has, in fact, been thoroughly learned at Karlsbad no doubt, in the first instance, under medical direction; for as I have said, the diet and regimen of those seeking a "cure" are infinitely better regulated here than in Vienna where indeed "tea" or one thing was never heard of. We have given our "Ceylon tea" to the waiter at an hotel to get infused, in entertaining friends to a cup of "high-grown, delicate tea," and the result was a perfect infusion and every justice done to the superior aroma. Here then in Karlsbad would be the place to introduce Ceylon tea, for the benefit of the restaurant-keepers (in giving them a better and no doubt cheaper article) as well as of the visitors. But it is not easy to see how a start in the business is to be made. The result of our enquiries goes to shew that at the beginning of each season, a Haniburg firm sends a large consignment of tea (valued according to our authority at 150,000 marks say £7,500) for sale to the cafés and hotels. I have not been able to learn exactly at what rate this is sold to these establishments, but I do not suppose any of it at less than the equivalent of 7s to 8s and for a tea which could be better supplied from Ceylon at 3s 6d duty, freight and charges all paid! I have only discovered one considerable tea-dealer-importer in Karlsbad—and on entering his office and asking for "Ceylon tea" we were told "there was no such description!" The information that we came from Ceylon which would this year perhaps send 70 million lb. of the article into

consumption, changed the answer into "We do not know Ceylon tea here"; and most interested then did the comparatively young Austrian principal of the firm become in all we told him of the new tea. He had a considerable stock of China which he sold in various classes—Congou, Souchong, Melange, &c. He had exceedingly neat boxes (made in Vienna) lined with lead, daintily papered with Chinese pictures outside, sliding lids, for forwarding 1 lb., 2 lb., or 5 lb. to customers—just as we had seen in Vienna itself exceedingly neat paper and lead packets for $\frac{1}{2}$ lb. and $\frac{1}{4}$ lb. with English and German inscriptions:—"Real China Tea—Extra choicest—New Season's First Crop China Tea—The China Tea Company, Limited." This is no doubt from a London distributing house. On another side of the package we read:—"This packet contains the choicest Chinese Tea selected with greatest care and experience. The tin foil and parchment packing is entirely free from lead, or other deleterious substance." And then on the fourth side, come very full and minute instructions in German as to the proper making of the tea, with, of course, a great deal of praise of the description enclosed. I have had a translation made and here it is, showing how well the Austrians are instructed to make tea:—

THE PREPARATION OF TEA demands the greatest attention in order to make it agreeable to the consumer to utilize its essential properties, its aroma and theine, and to make it valuable in point of economy, hygiene and taste.

THE FOLLOWING METHOD IS RECOMMENDED.—Soft water of pure taste, every time fresh is most suited for the extraction of the aroma and theine of the tea leaves. Hard water contains minerals in solution, such as iron, copper, saltpetre, salts of all kinds and other substances, and is therefore unsuited for tea-making which process is simple but must be carried out rationally and precisely. A tea-spoonful (about 2-2½ gram) is sufficient for a large cup or glass, the water must be boiling hot, until all frothiness has ceased and then poured on; by this means the drink is clearer. The tea-pot which is used for tea only must first be rinsed out with hot water, the tea must be left 5 minutes after the water is poured on to it, but avoid any further boiling of the water after it is poured over the tea. If one requires weaker tea, then 3 minutes will suffice for extracting the aroma and theine and the strength can be regulated by adding boiling water. Properly prepared tea must be golden yellow and quite clear. The brewing of tea beforehand, that is the pouring away of the first infusion of boiling water, which is so often done, is certainly not to be recommended as thereby much aroma is drawn from the tea.

To return to the Karlsbad dealer: he seemed very free from prejudice and ready to apply for samples and a small consignment of Ceylon tea to begin with, to the Colombo house (whose address we ventured to give him—Messrs. Volkart Brothers as representing his country, Consulate and national Steamer Company there.

The more I think of it, the more I am completely puzzled as to the enormous difference in the prices at which Coffee, Cocoa and Tea are respectively retailed, or even sold wholesale throughout Austria. The difference in duty does not account for more than a fraction of the proportion. Nothing but habit, and the custom of treating tea as a "medicine" can account for it, along with the fact that the import business is confined to a few who are quite content with their position. [The parallel case is to be found in the treatment of "quinine" in England, still retailed at 1d a grain equal to £2 an ounce!] For instance, we went into a leading grocer's here this morning, and asked him for the retail price of the three products. Here is the

result:—

TEA (Cibira, almost entirely) 5 to 8 gulden (8s 4d to 16s 8d per lb.)

COFFEE (Ceylon U10 gulden 1s. 10d) 1 to 1.20 gulden (1s 8d to 2s per lb.)

COCOA (prepared in Vienna) .80 to 1 gulden (1s 4d to 1s 8d per lb.)

COCOA (Van Houten's imported) 2.50 gulden (4s 2d per lb.)

I have further learned that the Hotels and Cafés even when laying a comparatively large stock of tea, pay not less than 5 to 6 gulden or 8s to 10s per lb.—the duty being but 10d. Now let the charges for "handling" at Trieste be what they may—the railway freight we know is very moderate and great facilities exist in Austria for sending even large packets or parcels by post—it is impossible that Ceylon tea retailed at half the current rates would not show a large profit. And can it be any wonder that the people never use tea? Again and again, our answer when pressing the virtues of tea, has been "Who can afford an article for household use at 6 florins (10s) the lb? While doing the cure or out on holiday at Karlsbad, we enjoy our little pot of tea (costing 5d to 6d for less than two cups of tea), but no house-keeper could go on at that rate." Again, one Dalmatian lady friend has said:—"I am very fond of tea; but a kilo is about all I use in a year," against I suppose some cwt. of coffee; for her husband holds a high official position in Spopolat. Again, a poor fruit-seller's view of the matter is worth giving:—"For 3 kreutzers (little more than 3d) even, I can buy an appreciable number of beans of coffee; but to get an equal proportion of tea, I should want 40 kreutzers!" Of the poor agricultural population, of course "drinking coffee" really means the slightest flavour from a very few beans to the sugar and a large quantity of milk. But if once they get to know *good cheap Ceylon tea* the same thing—and even greater economy—would hold good. I have done; but before closing I should like to make one or two suggestions more to the Ceylon Tea Fund Committee. I think the publication, and wide though judicious dissemination of a pamphlet in German giving an account of Ceylon Tea, its growth, preparation, analysis, different kinds and corresponding qualities, together with information respecting tea generally, in a popular form, could not fail to do much good, more particularly throughout Austria—in Vienna and Karlsbad especially—but also throughout Germany and all the German-speaking parts of Northern Europe. If illustrated, the pamphlet would be all the more useful in aiding the sale and use of Ceylon teas. Again, before the opening of the next Karlsbad season, or early in 1892, I think the Committee should arrange to send free packets (as samples) of Ceylon Tea to every Medical Doctor, Hotel, Café or Restaurant in Karlsbad, with their compliments and perhaps one of the "Tea Circulars" prepared in the *Observer* office, wrapped round each.

THE INDUSTRIAL FUTURE OF AUSTRALIA.

At a time when political changes are going on in our Australian colonies—when in a scene that is our approaching political manhood—"An Australian" takes occasion to survey their condition and cast their horoscope. We need to be reminded of the things described in the articles entitled "The Commonwealth of Australia," the second of which we publish to-day. They make us understand the pardonable impatience of colonists at the ignorance of Englishmen as to the great Island Continent, peopled by their own kin, and they give the impressions of an Australian, who,

visiting England and seeing its industrial achievements, is not the less pleased with them, because he knows that in his own land the same race is repeating the triumphs which made England what it is. Our contributor takes stock of the resources of his country, at a time when its political future may be uncertain, but when its industrial future is assured. In days when Australia was very little known, it was supposed, for slender and fantastic reasons, to be doomed for the most part to sterility. Its fauna and flora seemed to be imperfect monstrosities. The gum-tree and the kangaroo were products of Nature bungling or at her worst, and geographers wrote harudly about the invincible barrenness and inherent poverty of the land. Even after the gold discoveries had given an impulse to Australia, it was taken for granted that it could have no feature comparable to that of the United States. But all such predictions have turned out erroneous; a vigorous race, full of resources, has set them at naught. The whole of Australasia is more than 26 times as large as the United Kingdom, more than 15 times as large as France, and almost equal to the Continent of Europe or the United States. Such are the figures, as given by Mr. Coghlan, the Government statistician of New South Wales—whose investigations respecting the amount of crime in the different colonies have made him known here, and our contributor shows that, far from being stricken with barrenness, very much of that tract may be utilized by Englishmen. The whole of New South Wales, South Australia proper, half of Queensland, more than half of Western Australia, all Victoria, Tasmania and New Zealand—that is, about 1,985,500 square miles—lie in the temperate zone. About two-thirds as much is within the tropics; but no small part has proved to be fit for Englishmen to live and labour in. "A tropical temperature," our contributor observes, "has never yet deterred gold-miners from working on a payable field. The quality of the wash-dirt or quartz, not the story told by the thermometer, decides their movements." And so he writes with confidence of the ease with which difficulties of climate can be overcome; and undoubtedly there are scarcely limits to the capacity in this respect of an industrious race. The Lombard peasant works longer, harder, and to more purpose, under a fierce sun, than the Irish peasant farmer. The industry of the fellah or the ryot is scarcely surpassed by that miracle of pertinacious thrift, a French peasant proprietor. Moral causes have as much to do with the matter as physical; the "white trash" in South Carolina and Georgia, who did not work because—as was said in slavery days—of the climate, now begin to do so, when slavery, is gone and the opprobrium connected with work has passed away. We should give no heed to the pessimist views about the capacity of Australia, and indeed all parts of Australasia, to be the homes of a vast people, if tropical heat were the only obstacle. But the tabular statement of the rainfall of Australasia reveals a more serious difficulty. "More than one-third of Australasia has to get along as best it can with an average annual rainfall of less than 10 inches. More than a fourth can only boast of between 10 in. and 20 in. And throughout all this dry country the rainfall is irregular as well as scanty." Even within the 10 in. line irrigation can do, and has, in fact, done, much; sheep are reared, and the finest wool is grown, where once was only a desert, varied by sparse, stunted vegetation. Tanks and wells are being dug; in New South Wales alone a sum of four millions sterling has been expended upon the construction of tanks. The

water-carrying strata have been tapped, with good results; and such is the promise of this source alone, that the death of stock by the thousands, by reason of drought, will soon be impossible. And, after all, if this be too sanguine, there remains a tract of nearly two million square miles, within which men and all that men feed upon grow and thrive, some parts of which are the most favoured in the world, and all of which may be utilized. Surely a magnificent heritage, fit habitation for a race with a great future.

And that such is before the Australians, they may well be confident. Of the four millions, in round numbers, who occupy Australia, the great majority are of our own stock; scarcely even is New England, as to race, more a part of Great Britain, accidentally detached, than is Australia; and nowhere have Englishmen laboured more stoutly and to better purpose. Mr. Coghlan's computations record rapid progress, of which the colonists may well be proud. In much less than a century of activity, Australia has accumulated a stock of wealth, which, he estimates, far exceeds that of Belgium, Holland, or Canada, each a comparatively old State. Such figures, however, can be but rough approximations—at best only very intelligent surmises. More trustworthy, and equally impressive, are the returns as to sheep-farming and other kindred industries. In the year 1889 there were one hundred millions of sheep, nine-and-a-half millions of cattle, one-and-a-half million of horses, and more than a million of swine. The value of the wool grown in that year, is put at twenty millions; the value of the year's produce to the growers, at thirty-five millions; and to this must be added the dairy produce, reckoned at over seven millions sterling. We all know the vastness of the flocks possessed by Australian millionaires; the conditions of economy under which they are fed are less understood. There is no need of artificial grasses; that which grows wild on the runs is generally sufficient. Labour is dear; therefore labour is reduced to a *minimum*, and, in place of the shepherd, who has all but disappeared, are wirefenced paddocks, within which the sheep roam at their will. The wool, too, is of the best; the original stock was good, and the climate has improved the qualities of the fleece.

These are magnificent results; and yet our Correspondent admits that agriculture is still almost in its infancy. It now takes about nine-and-a-half acres to produce annually a single fleece of wool; but this, he explains, is owing to so much land being completely unstocked. If it all carried as much as New South Wales, there would be six hundred millions more sheep than now exist. No wonder the Australians are hopeful, when their statisticians and agriculturists tell them that they may soon expect to have a clear addition to their present flocks of as many sheep as are now fed in Europe, five times the number in Asia, six times the number in Africa, and more than exist in North or South America. Economists have explained that agriculture in its development follows certain laws: that when population is small and land plentiful, stock-raising is remunerative and necessary; that, as population increases, agriculture becomes more "intensive," and huge flocks become things of the past. At no great distance from Melbourne and Sydney this evolution has long been completed. Elsewhere agriculture is still in the earliest stages. Even in Victoria and New Zealand the cultivated area is only 3.73 and 2.07 of the whole, while in Queensland, South Australia, and Western Australia it is the insignificant proportion of .05,

.39, and .01. If our Correspondent's hopes are well founded, the greater portion of what now lies useless, except for stock raising, may be put under crops; and, when this transformation takes place, the wealth of Australasia will be immensely increased. It is a simple calculation; if the value of agricultural produce was seven-tenths of that of the pastoral produce, when, to speak generally, only one-third of one acre out of every hundred was under cultivation, what will be the value of the former when the country is cultivated as Scotland or Ireland? Of the future of Australian commerce one must speak only with diffidence. Economists and historians have not discovered the complex laws governing its growth. But the results so far entitle one to hope the best. Seven tariffs, more or less hostile to British goods, have been in operation; but everywhere, even in Victoria with its high protective duties, trade has expanded by leaps and bounds. The total external trade of Australasia in 1889 was valued at £76,384,000, of which no less than 77 per cent. was with Great Britain. In a single decade the colonial external trade increased by more than £24,000,000. It will surprise many Englishmen to be told that, as to shipping, "within the Empire Melbourne is exceeded in absolute tonnage only by London, Liverpool, Cardiff, and Newcastle,"—with the addition, as Sir William Des Vaux has pointed out, of Hongkong—and that within the same limits "Melbourne is exceeded in population only by London, Calcutta, Liverpool and Glasgow, while only Birmingham and Madras are to be added to the list before Sydney is called." These things are outdone by no achievements of industry in the same space of time. In the last century, poems would have been written about them. In glowing heroics would have been described the silent, lonely and miserable land, becoming, as if by magic, rich, prosperous, people with flocks and herds, and vocal with the sounds of human industry. In still earlier ages, had such things come to pass, the story would have been, after the manner of Herodotus, of some people driven from their homes, finding a strange land, pleasing by propitious sacrifices the gods, who poured upon the new-comers the best that Heaven could give. Such accounts, the poem as well as the legend, would have been true; for it is the magic of courage and enterprise, the propitious sacrifice of unremitting toil, which has triumphed over all difficulties, and worked the marvels described in "The Commonwealth of Australia."—*Times Weekly Edition*, Sept. 1.

[We had the pleasure of a visit from Mr. Ward, the author of the able articles referred to, when he was on his way home. He had been associated in Australian journalism with Mr. Gullett, who some dozen years back was in Ceylon.—Ed. T. A.]

PERSIA AS A FIELD FOR ENTERPRISE.

Persian commerce affords us a very striking example of what may be attained by perseverance, and a resolve to tenaciously hold on to a definite scheme of working. The British India Steam Navigation have persistently pushed business in the Persian Gulf, and have created by their efforts a valuable stream of commerce which before their advent did not flow, although the materials for it existed. This point was fully brought out by Major-General Sir R. Murdech Smith in the address he read before the London Chamber of Commerce in February, 1889, and a full report

of which appeared in this *Journal* of March that year. Those who would wish to trace it more closely, and also to ascertain in detail the great wealth and variety of the natural products of Persia, may find a mass of information brought together in "The *Livor Karun*: an opening to British Commerce," of which Mr. W. Francis Ainsworth is the author (and Messrs. W. H. Allen & Co. publishers), and who speaks from personal acquaintance of the district surrounding the Karun. One fact is evident from the writings and remarks of all authorities on the subject of the prospects of British trade in Persia, and that is—that whilst competition with Russia in the more northern parts may be difficult owing to her exceptionally favourable geographical situation accorded by the "iron road" developments which she is ever pushing eastwards and southwards, yet, in the southern, and far into the central portions of Persia, British commerce may penetrate with success under fair conditions, and defy the competition of northern traders. * * *

An idea of the progress which has been made latterly is afforded by the statistics given in the report by Mr. Consul-General Ross above quoted, which relates to the trade of Southern Persia and the Persian Gulf for the year 1889. Taking the bare totals alone we obtain the appended comparison for the various places of import and export, with the value of the trade in 1888:—

	All Imports.		All Exports.	
	1889.	1888.	1889.	1888.

—Chamber of Commerce Journal.

A TALK ABOUT TEA.

The weather recently in Assam does not seem to have been as favourable for tea-making as it might have been. Upper Assam, in particular, has apparently been suffering from something very like a drought, if such a word can be applied to the rainy season. From Tezpur I hear "we have had a very, very dry time since the commencement of August; only six inches of rain during the whole of August, and 1.33 inches up to the 10th of September." This is an abnormally small quantity of rain for what is generally the wettest month in Assam. There were very heavy falls of rain during July, but this will not carry on indefinitely. A hot August, with little or no rain to speak of, soon dries up the soil, and a heavy consequent drop in the outturn is to be feared. Planters seem to think an early cold weather is impending. Notwithstanding the unusual heat in the day, due to want of rain, the mornings are already assuming a "cold weather" feel and appearance; and the "snows"—as the distant snowy mountains' peaks are locally called—stand out in the early morning as clear and clear as they generally begin to do about the end of October or beginning of November. Every one is complaining of the heat in the day; and the now popular Blackman's fans for withering leaf are at a discount; the leaf withers in the lofts only too quickly without their aid, owing to the abnormal heat. Yet up to date most of the gardens are keeping up to, if not ahead of, last year. One big garden in the now well-known Daputa Valley is over 1,000 maunds ahead of last year, on a crop of 7,000 maunds for last season; and its manager hopes to turn out nearly 9,000 maunds, notwithstanding the scanty rainfall. But to this incense a good deal of young tea coming into bearing is contributing. Other gardens without new extensions coming in to their aid will probably feel the unusual

weather severely; and a considerable drop on the estimated outturn of tea will probably have to be faced by many concerns in Upper Assam.

Dibrugarh tells the same story. Spasmodic showers, occasionally heavy, but very much localized, are the order of the day. Heavy clouds, thunder and lightning all round, but very little of that good, steady, soaking rain, that fills the heart of the planter with joy, and covers his boats with mud, is reported. Everything seems to foretell an early cessation of the rains, and all but very low-lying gardens are sure to suffer in outturn in consequence. But "every sorrow has its twin joy." If the comparative failure of the rains is general, the general, outturn of the district will fall considerably below estimates; and when this fact is publicly appreciated, a rise in prices may be looked for in the home market. There is considerable room for a rise in prices at present. Just now they are tending to such an average that the planter may be forgiven for parodying the much-quoted question "Is life worth living?" by querying "Is tea worth making?" And yet it goes on being made, and new extensions and new gardens are being opened out as freely as in the palmy days of old, when a twelve-anna average was as common as a six-anna one is now-a-days, which brings forward the great question "Does tea pay?" There is an enormous amount of capital sunk in tea, and a great number of anxious shareholders would like a satisfactory answer to the question "Does tea pay?" There is no doubt that, for some of the old gardens, put out on bad or unsuitable soil, with poor *jal*—wretched China plant incapable under the best management of making over four maunds per acre—it will not pay. And the numerous extensions one hears of are recognition of that fact, for gardens that, owing to bad soil or inferior class of plant, cannot be kicked or coaxed into more than three to four maunds per acre, the only hope is to extend on better soil with higher class seed, with a view to eventually abandoning the old unproductive area that does not pay the cost of keeping up. But for the latter class of gardens opened out on good rich soil with high class plant, capable of yielding anything from eight to twelve, or in some cases even fifteen maunds per acre, tea will pay handsomely, and go on paying even in the face of a lower market than has yet been reached. Some of the statistics of private gardens opened out within the last eight or ten years would, if published, be deemed incredible by the general tea shareholding public, or if believed in they would create a frantic rush to "got into tea;" for these gardens which pay such handsome profits, and of which one hears little or nothing, have been opened up by practical, experienced planters who have chosen their land with ample local knowledge, and in some cases bought their experience pretty dearly. And to make a concern that pays as some of these private concerns do, or to get into them when made, is only given to the initiated few. We hear or read in the published share quotations of dividends of fifteen and twenty per cent. But of the plums and prizes of tea-planting the outside public hears nothing at all; and, it told of tea gardens that pay twenty-five and thirty per cent,—or of a garden that, in its tenth year, gave a clear profit of over one hundred per cent on the original capital invested,—would turn a deaf and incredulous ear. And yet such a profit has been made, although, it is not quite so good as it appears on the surface. It was a matter of foregoing any intermediate profits for nine years. After the third year, at an outlay of some £70,000 roughly, the garden began to pay. The partners agreed to put all profits back into the concern instead of drawing them out, thereby extending area, increasing plant stock and labour force considerably. The first division of profits took place, say, in the tenth year, when a lakh and-a-half of rupees clear profit on the season's working was divisible. Thus an original out of pocket outlay of £70,000, with its earned increments for nine years, brought back the original capital and something over a hundred per cent to the pockets of the fortunate partners. This seems to be a very satisfactory answer to the question, 'Will tea pay?' and it is a fact. Everything comes

to those who know how to wait. It must not be inferred that tea always pays like this, very much the other way. But this is an instance of what tea in experienced hands and under exceptional advantages can do. This extraordinary profit has been made in tea, in the face of the enormously increased outturn and consequently heavy fall in prices which has marked the last decade. It by no means follows that every planter with a few year's experience and local knowledge can take up a grant of land, open out, and do likewise. A good many have tried and failed. Nothing succeeds like success; the few succeed, the many fail. But it has been done, and it will be done again; and though cent per cent is not to be looked for, as in this one special case, still tea as a business will make, as big, if not bigger, profits than any industry under the sun.—*Englishman.*

MR. JAMES TAYLOR'S REMINISCENCES OF THE TEA AND CINCHONA ENTERPRISE.

Mr. Baker of the Assam Tea Company, mentioned by Mr. Taylor, was here during the heavy rains of the north-east monsoon of 1874; and they made such an impression on his mind that he told us he could not see how, with so wet a climate and no winter, tea could flourish in Ceylon. The result shows how even experienced and acute observers may be mistaken. And so as regards climate. Our visit to Darjiling was in March 1877, at the culmination of seven months of drought; and we might, as our good friend Mr. Gammie of the Moungpoo Cinchona Plantations said, have formed the impression that it never rained on the Eastern Himalayas; while Mr. Taylor, judging by his opposite experience, might have reported that it never ceased raining. The late Mr. Critwell accompanied Mr. Taylor on his trip to Darjiling and wrote a very interesting account of the Sanitarium and the tea estates for the *Observer*. Mr. Taylor's experience of actual tea cultivation and manufacture at Darjiling must have been of great value to him. Mr. Taylor's gratitude to those who have recognized his services in first manufacturing Ceylon tea in appreciable quantity and of good quality is very creditable to him. But his own bashfulness, which he describes as of even more than ordinarily Scotch intensity, might have induced him to spare the blushes of another notoriously modest man, Mr. George Wall. This gentleman is notorious for never regarding differences from his opinions as criminal. When people assert opinions different to his he merely says, like Mr. Toots, "It's of no consequence." How distressed this model of modesty and self-depreciation will feel at being supposed capable of permanently occupying the chair of the Planters' Association. Charles Lamb said he could sit against anything except a hen or a tailor; but Mr. Wall bears no resemblance to a student Buddha. There were great generals before Agamemnon; and Mr. Robert Boyd Tyler and "Sandy Brown" were for many years the life and soul of the Association. Statistics of the various crops in Ceylon, which we furnished to Mr. Tyler, were embodied in the paper announcing the formation of the body which has done so much for the planting enterprise and Ceylon. Then the Birds, or Byrdes as they now call themselves; and others, notably Mr. Leake, and now that Prince of Secretaries, Mr. Philip, have rendered good service, which Mr. Wall would be as ready to acknowledge as Mr. James Taylor must be. Gratitude is a fine quality even when expressed rather gushingly; and we are all grateful for the work done for the colony by Messrs. James Taylor and George Wall. But others have done their part, amongst whom Mr. James Taylor, if he had not exhausted the English

language in glorifying his special idol, might have mentioned the conductors of the *Ceylon Observer*, but for whom Mr. Taylor's merits would not have been so well-known to the world as is the case. But returning from this digression, necessary in the interests of impartial history, let us express the hope that Mr. James Taylor may live long to enjoy the well deserved honours conferred on him by his brother planters, not for introducing either tea or cinchona, but for the service rendered to the colony by a series of intelligent, careful and successful experiments in the cultivation and preparation of both.

THE TAYLOR TESTIMONIAL.

The Secretary of the C. P. A. sends us the following correspondence:—

Copy. Secretary's Office, No. 42 King Street, Kandy, 19th August 1891.
To James Taylor, Esq., Loole Condara.

Dear Sir,—I am requested by the Committee of the Planters' Association to inform you that the Silver Tea Service which forms part of the Testimonial to be presented to you has arrived from London and I am to ask you whether you would prefer to have the testimonial presented to you at next meeting of the Planters' Association or to have it handed to you privately.—I am, dear sir, yours faithfully,

(Signed) A. PHILIP,
Secretary to the Planters' Association of Ceylon.

Copy. Loole Condara, Aug. 21st.
A. Philip, Esq., Secy., Planters' Association, Kandy.

Dear Sir,—Your letter of 19th current received. I am very much obliged for the suggestion that the Tea Service Testimonial can be handed to me privately. I would much prefer that course and I would write a letter of acknowledgment to you and thanking the subscribers, &c. and giving some short and general account of our beginning of the Tea industry. Were the testimonial to be presented at a meeting of the P. A. I should have to speak something of that nature. It would be my first attempt at "public speaking" for which I am certainly not fitted, and I would rather be allowed to write what I should try to say.—Yours faithfully,

(Signed) JAMES TAYLOR.

(Copy) Secretary's Office, No. 42, King Street, Kandy, Aug. 31st, 1891.

To James Taylor, Esq., Loole Condara.

Dear Sir,—I beg to acknowledge receipt of your letter of the 20th instant and have now only to perform the pleasing duty of handing you on behalf of the subscribers the accompanying tea and coffee service. On the silver salver is engraved the following inscription:—

"To James Taylor, Loolecondara, in grateful appreciation of his successful efforts which laid the foundation of the Tea and Cinchona Industries of Ceylon 1891." and no words are needed to express the hearty and representative nature of the testimonial.

You are doubtless aware that a portion only of the "Fund" subscribed has been devoted to the silver tea set; a cheque for the balance will be sent to you as soon as the accounts have been received and closed.—I am, dear sir, yours faithfully,

(Signed) A. PHILIP,
Secretary to the Planters' Association of Ceylon.

(Copy.) Loole Condara, Sept. 23th 1891.

To the Secretary Planters' Association, Kandy.
Dear Sir,—In acknowledging receipt of the Testimonial I feel that I do not know how to express my thanks for the honour and reward it gives me for my original successes in Tea-making and Cinchona cultivation. It had been publicly mentioned on several occasions that I was the first successful tea-maker in Ceylon or in the beginning the most successful. I was fully satisfied with that, and it was a startling surprise to me when I saw mention made in the newspapers of this testimonial.

The credit for the starting of the tea industry as well as cinchona planting in Ceylon belongs to Messrs. Harrison and Leake as Kehr, Dundas & Co. who were my employers and proprietors of Loole Condera. It was they who allowed me to plant cinchona and ordered me to plant tea, and it was they who paid for these things and stood the risk of failure. I took much interest in these cultivations, for I had before thought myself that surely something else besides coffee could be profitably grown on our estates.

With regard to the manufacture of tea I learned that mainly from others and from reading, but it took a lot of experimenting before I was very successful. About the time we began planting China tea from seed got from Peradeniya Garden a Mr. Noble, an Indian tea planter from Cachar, passed through to see a neighbouring coffee estate that some of his friends were interested in, and I got him to show me the way to pluck and wither and roll tea with a little leaf growing on some old tea bushes in my bungalow garden. It was all rolled by hand then. He told me about fermenting and panning and the rest of the process as then in vogue, showing me the fermenting and panning as far as circumstances permitted. After that I frequently made experimental lots as I got leaf to pluck.

Afterwards when Mr. Jenkins of the Ceylon Company, an old Assam tea planter, came to the country he called on me and I made a batch of tea under his direction. A sample of this and samples of seven lots that I had made before were then sent up to Calcutta together to be reported upon and valued. Mr. Jenkins' sample was valued a little higher than any of mine, but mine were also pronounced good except one indifferent and one spoiled. With these exceptions both Jenkins' sample and the rest of mine were said to be better than the most of the Indian teas that were being sold in Calcutta at the time. From this I saw that I had been making tea rightly enough, but as I could not get it to taste like the China tea of the shops I had been always varying my process and spoiling batches of it in various ways sometimes purposely to see the nature of the results and throwing away lots that were no doubt really good tea, some of which was used by other people and pronounced good. Nevertheless I benefited largely by Mr. Jenkins in various ways, and that sample of his being better than mine settled me as to the degree to go to in the different parts of the manufacturing process and gave me confidence.

Up till this time all my makings of tea had been made with arrangements in the bungalow verandah and godowns. But I got a tea house finished soon after and regular tea making then became a necessary part of the working of the estate. Afterwards Mr. Jenkins put up a temporary tea house on Condegalla which I was surprised to find was a copy in all its working parts and arrangements of the one I had built which was according to a plan of my own and different from the style of Indian tea houses, and Mr. Jenkins did not like it when he first saw it.

But Mr. Jenkins did not then make as good tea as I did. On visiting his tea house I found his tea very different from the lot he made with me and very different from what I was making; and his fermenting which I saw by ramming the roll as hard and tight as possible into a box was a plan that I had tried in the beginning of my experiments but long before given up as a failure. The lot Mr. Jenkins made with me at Loole Condera was not fermented that way. One day I was in the coach going up to Nuwara Eliya with Mr. Parsons, Government Agent of Kandy, and some apparently stranger friend of his, Mr. Parsons did not know me but I knew who he was. When we were passing the old patch of tea in Condegalla Mr. Parsons pointed it out to his friend as being tea. His friend then asked if they made tea there. Mr. Parsons said: "Yes, they make tea here but they do not make good tea here, the favourite tea is made on another estate they call Loole Condera," and from other quarters I heard the same.

A Mr. Baker, a tea planter from Assam, called on me after my original field of Hybrid Tea was well grown up and showed me that I had not pruned it sufficiently in the pruning I had just then finished and I pruned it all over again. I also saw light pruning and heavy cutting down of Hybrid tea in the Darjeeling Terrai in 1874 just before their plucking season commenced. Afterwards when Mr. Cameron came and took to visiting tea estates I was pleased to find that his pruning so far as I saw of it on Mariawatte seemed to entirely agree with what I had done.

But Mr. Cameron started finer plucking than I had been doing and began to top the sale lists which I think we began to get about that time or very shortly before. When I found this I also took to weekly plucking and topped the sale lists for a time. That finer plucking largely increased the selling prices of my tea and still more largely the profit per acre. So I was greatly indebted to the example of Mr. Cameron though I only met him two or three times casually about Kandy and Campola.

Regarding cinchona we were not the first to plant a few trees or even a small patch but we were the first to regularly cultivate a few acres and to test the value of the bark in the market and then to start the cultivation on a large scale. Our experiences as to raising seedlings in field nurseries and that the bark of diseased trees if taken in time was valuable, and so on, must have been useful to others who planted later.

Looking back to the beginning of our Cinchona and Tea experiments and recollecting how little they were generally thought of at the time, especially by some of my acquaintances whom I most respected as in various ways superior to myself, and now seeing this testimonial makes me feel that the battle is not always to the strongest. The first person I believe who thoroughly appreciated our experiments and who really foresaw the necessity of new cultivations in Ceylon was Sir William Gregory; and Ceylon Tea is more indebted to Sir Wm. Gregory who so patronised it and gave it fame than we can ever know.

Now I thank all who have helped towards this testimonial and the office bearers of the Planters' Association who have taken trouble with it and Mr. P. R. Sband who as I learned from the newspapers took part in initiating the matter, and especially I thank Mr. Wall who first proposed it to the Association in words which are of themselves a grand testimonial and who has taken a leading interest in it all through. It made me feel confused and surprised that I should be thought worthy of such honour as well as of the kind things said of me at that meeting by its Chairman and Mr. W. Mackenzie.

The Testimonial is not only a valuable one but one of a kind to make me remembered after I am not here. It will make my name and that of Loole Condera live in the history of Ceylon. I shall be proud of it though abashed in the receiving of it.

But if I may be allowed to make remarks about one so much my superior and so far above me Mr. Wall is the man who deserves a memorial from the Planters' Association. He has been by far its most conspicuous and leading member from the first, until latterly perhaps that he has not been so much amongst us for some time. It has seemed to me that but for his own will he might have been permanent Chairman of the Association; and he was one of the leading men connected with our planting industry before the Association was formed. I suppose few of the men of old who knew Mr. Wall in the earlier years of his labours now remain. But I from reading of them in newspapers have known of his ceaseless exertions for the good of our planting enterprises and of the Association for a very long time.—Yours truly,

(Signed) JAMES TAYLOR.

NOTES ON PRODUCE AND FINANCE.

TEA DIRECT TO LIVERPOOL.—We print in another column some suggestions made by the *Liverpool Journal of Commerce* in favour of the direct shipment of tea to the Mersey. The journal from which we quote

remarks that it seems strange in view of the fact that the shipowners of Liverpool are the largest carriers by sea of any port in the world, that Liverpool merchants should buy their teas in London. It is undoubtedly strange. Indian and Ceylon tea planters would, however, be very glad if the idea suggested in the *Journal of Commerce* were acted upon, anything tending to increase the sale of tea in the north of England and in Wales being greatly to their advantage. London brokers and dealers, no doubt, see the matter in a very different light.

A PAT ON THE BACK.—Ceylon planters have no cause to complain of the amount of advice gratis showered on them. The *Financial News* says: "Since we last referred to Ceylon and Indian teas the new season's imports have assumed large proportions, the excess over last year of the Ceylon product alone being 50,000 packages, and the increased shipment from Calcutta 30,000 packages. The hopes of British tea planters, and those of Ceylon particularly, must rest less upon a large output than an improvement in the quality and 'keeping' properties of the leaf; and from that point of view it is satisfactory to find that the more recent shipments are marked by an advance in quality, and are realising better prices than the earlier parcels."

LAST WEEK'S TEA MARKET.—Discussing last week's tea market, the *Grocer* says:—The market is suffering from a state of uncertainty. Supplies from India up to date have been some 4,000,000 lb over last season, and the total output for 1891-92 is estimated to reach some 10,600,000 lb more. China export up to date is also some 400,000 lb over last year, but there the season has been earlier, and we are told that the total export from China will be from 10,000,000 lb to 15,000,000 lb less than last year. The present state of the market is most unsatisfactory, and ruinous losses are already being faced, but such a state of affairs must materially affect the ultimate supply. Ceylons are at last beginning to come in in moderate quantity, and as the quality is improving, so are prices, and there is no getting away from the fact that Ceylon tea is carrying everything before it. We are suffering greatly from the want of an export demand in the open market—yet export figures are good up to date. Dealers say they are doing no trade, yet the weekly deliveries are splendid, and continue to show increase upon increase. The general position is a puzzle, and it makes one come to the conclusion that the trade is going into a few hands. Supply and demand hold the key to the position—two or three millions too much may lower prices pence per lb. and vice versa. The bulk of the supplies from all parts are of poor and undesirable quality. Taking into consideration the circumstance that this has been another week of excessively heavy supplies, and that the trade requires more breathing time to work off the extra large quantities that have, as it were, been forced upon them of late, it must be admitted that the market for Indian tea has maintained great steadiness since our last report, for no less than 31,000 packages Assam and other kinds have been offered at public sale, and have been nearly all cleared. The common qualities, as usual, have been the sorts to suffer more from the effects of over-supply than most other descriptions, and as even some of these have been rather worse than better than the ordinary run of New Season's teas, their disposal has not been completed without holders occasionally submitting to lower prices; otherwise the almost too numerous auctions have passed off fairly well. Supplies of Ceylon teas coming forward are getting smaller, and the market is firm. Finest grades are scarce, and sell at hardening prices. Low and common kinds continue to sell at very low rates. Much of this tea would be scarcely saleable if it was not Ceylon, and proves what a hold it has in the country. The depression in the market has been due to the almost entire absence of fine grades. The *Produce Markets' Review* says:—The large imports have amply supplied the market with a good general assortment of Indian tea. The demand for most grades is active, and prices, excepting for the commoner sorts, have on the whole been maintained. For the lowest grades the market

has now touched a point which will enable them to be more generally used in the commoner blends, and buyers have purchased more freely, as these teas now compare favourably with the values of the lower kinds of Ceylon growths. However, as the proportion of the lower grades bids fair to be large, and quite sufficient to meet any reasonable increase in the consumption, the market will in doubt continue favourable to buyers for some time to come. For the medium kinds there has been a good enquiry, and excepting for teas giving a poor infusion, which sold at easier rates, prices have remained steady. The fine and finest descriptions continue to meet with brisk competition, especially the Assam and Darjeeling growths. The supplies of Ceylon Teas have again been comparatively small, and prices have been well maintained; there is, however, so far, no appearance of a repetition of the large advances in rates which took place last and the preceding year, and buyers have not apparently purchased in advance of requirements, except, perhaps, of the lowest grades, and these not to any great extent. The shipments for the present month bid fair, however, to be small, and the stock at the end of the month will probably be reduced some two million pounds. The quality of the present supplies still maintains the late improvement, and the demand for the country is consequently quite satisfactory.—H. and C. MAIL.

SPECULATION IN TEA.

To the Editor of the *Home and Colonial Mail*.

Sir,—In your article entitled "Speculative dealings in Indian Tea," in last week's issue, you suggest the necessity of "combined action" on the part of tea importers to avoid an "undue disturbance of value."

You do not disown the moral difference between a "bull" purchase and a "bear" sale; but your readers will, I should think, fail to note any nice distinction. You invite importers to lay their heads together to regulate supplies, but you reflect on what you call the "bear game." I should say that one transaction is as moral as another. If I have reason to believe that prices will be lower this day month I can make plans accordingly. If another man thinks that by holding back his tea he can affect the price let him do so. As the rumours for and against the market thny count for nothing. Statistics are open to all and each must judge for himself. Any number of arguments about regulating the supplies will not affect the law of supply and demand. It is impossible to "bull" the tea market to any appreciable extent, although as you say an attempt is occasionally made to "bear" it.

Tea, like the other products dealt in in Mincing Lane, must take its chance. It is part of an importer's business to study the market and do the best he can with his produce; but I doubt if he will effect much by endeavouring to regulate the supplies. My opinion, as a constant reader, is that your Journal has done much for tea planters, but I do not see how the latter are to gain by taking your advice in this instance.—I am, Sir, yours obediently,

OBSERVER.

[We publish the above letter, but decline to discuss the speculative operations in tea from their moral standpoint, although we should give a "bull" operator the best of it on a question of the kind. Our argument in the interests of Indian and Ceylon tea growers was that a "bear" of either stocks, shares, or produce does his best to depreciate the market, and that this, so far as tea is concerned, is an important matter to planters and importers who rely upon disinterested advice from London as to the state of the market. In the interest of the tea grower we deeply regret that tea has been introduced into the game of speculation. Our correspondent's contention that a useful purpose is served by regulating the supplies placed on the market must be taken for what it is worth, and in our opinion this is very little. It does not require the exercise of remarkable wisdom to arrive at the conclusion that if a commodity is rashly hurled on a market already overstocked, the effect on prices is not stimulating, nor is it calculated to give them an upward tendency.—ED. H. AND C. MAIL.]

PRICES OF TEA.

The one engrossing topic just now is the market, and how long extensions will be carried on at the present unremunerative prices! What! We hear some people say, unremunerative! but, wo shall say, unremunerative! for, if some gardens with a big yield per acre can stand the present range of prices and give good results, there are far more that cannot possibly *live* at them! In the Annual Administration Report on tea the outturn for the whole district is put down at 362 lb., or say, four maunds, and, in the Habro-gunge Sub-Division, the outturn is estimated at 591 lb. per mature acre, so that, when the average only works out four maunds per acre, there must be a number of gardens only yielding between two and three maunds per acre, and, at present prices, what does this mean? Let us examine and we will soon find out. What is a moderate estimate for local expenditure? Is naturally one of the first questions to be answered, and although there are slight variations from local causes, yet we hardly think any one will consider Rs 90 per acre a high estimate, in fact, our idea is that it is seldom, or ever, done at this figure. However, let us take this figure as fairly approximate, and, we find, that at six annas per lb., it takes a yield of three maunds per acre to cover local expenditure, not to speak of Agents, Brokers, and other charges in Calcutta, or London. At present rates of exchange six annas represents 8d to 8½d., and if one turns up the Home sale lists there are not many Sylhet and Cachar gardens getting anything over this, and we have the other charges alluded to above to add on; so that a very large number of gardens must, just now, be turning out their teas at a dead loss! Were Ceylon differently situated as regards labour, the fight for supremacy, which is now only beginning, would have been a much tougher one than it is likely to be.

Hitherto Ceylon has to some extent prospered by having factories &c., made to hand &c., but now that such strides have been made further into the interior new factories must be built, and labour imported, to meet the increasing area being brought into cultivation and the shoe will pinch new, where it did not before. True, Ceylon may scare a little by cheaper freights, but it cannot get its labour cheaper, hoe cheaper, roll, or fire cheaper, or, as cheaply as Assam, Cachar, or Sylhet. And outturn, so far as one can judge, is about the same average scale as in India. The chances then are, viewing the matter from an unprejudiced light, that, in the long run India will beat Ceylon in growing tea as a paying industry, but, there will be a tough fight before this is established.* The Ceylon men have a great knack of advertising, and pulling together, which adversity will teach their Assam brethren, and the day is not far off, now; but it is to be hoped, that the Assam planter will not be so sanguine as the Ceylon one; and rush any new industry to such an extent, as to reduce it in a few years, from a safe investment, to a dangerous speculation. Unfortunately, if any one follows the history of the spicy isle a record is found of either great success or great disaster; and the characteristic of the Ceylon planter is not originality, but a stubborn persistence on a road which experience has proved practical. In spite of all the go, &c., displayed by the Ceylon planter, there is no record to relate of any original industry in the island being a success. Coffee was known and cultivated in many other countries before it was introduced into Ceylon. Cinchona, had a rush for a time, but it has, more or less, been abandoned of late years, although it still continues to be successfully cultivated in India. Coca, has never done much, India-rubber is now almost unheard of, and lately nothing but tea has been talked of and is likely to be for years to come, as many hundred acres planted out lately, unless the tea market improves or other outlets are found for the produce, will never be plucked, and Ceylon, will again be to the fore as it was a few years ago.†

* No doubt of it, and we suspect Ceylon planters are not prepared to concede the victory to India.—Ed. T. A.

† What is an original industry, and how is India superior to Ceylon in this respect?—Ed. T. A.

‡ The wish being father to the thought. The snarling at Ceylon is despicable and unworthy.—Ed. T. A.

It is absurd to think that banks will go on financing tea concerns against a certain dead loss, and this is what it will come to with many concerns by the end of the season. Concentration and amalgamations may, in some instances, stave off the evil day to a few concerns, but this will not be general, and 1892 will see many concerns in the market, without a buyer even at nominal rates. How many gardens can turn their teas out at four annas per lb. local, and Calcutta, expenditure included? Very few we say—and yet this must be done, if a fair profit is to be reaped. Improved machinery has done a great deal to cheapen the cost of tea per lb. but there is a limit in even this, and although economy has been effected in this way we are much afraid that as long as tea exists, cultivation will cost the same; for the coolies wage does not get cheaper! In Cachar and Sylhet, doubtless, were the railway a *fait accompli* there would be a slight reduction in cost of importing a coolie, but it would be fractional per acre; and the only hope in view is a limit to extensive, which is now we think looming in the near distance.—*Indian Planters' Gazette.*

NOTES BY "WANDERER."

October 15th.

Our American cousins seem to be keeping to the front as manufacturers of Bogus Tropical Products. Nutmegs formerly had their attention, but coffee now seems to be favourite. It is calculated that 90,000,000 lb. of bogus coffee are sold in the United States. The Germans followed suit, but a cruel Imperial Government has nipped this industry in the bud, for an Imperial decree has been issued in Germany forbidding the manufacture and sale of machines for producing artificial coffee beans, which certain German newspapers have of late been extensively advertising. Would that the British Government took equally strong measures to protect the pure Ceylon tea industry against the unscrupulous villains, who so cunningly hoodwink their customers, generally of the poorer class.

Rice.—I note the following in the *Indian Agriculturist's* summary of trade in Calcutta:—"The quantity of rice exported rose from 5,366,807 cwt. to 7,066,443 cwt., the increase being chiefly due to larger supplies drawn by Ceylon." When are these wonderful irrigation works in Ceylon, on which so much money has been spent to the prejudice of reproductive works, such as railways, roads, education, to be of use in enabling Ceylon to keep the money she sent to India for her food supplies? Echo indeed answers where?

ROYAL BOTANICAL GARDENS IN CEYLON.—Is Dr. Trimen now in a position to give an equally favorable account of his gardens as is given of the Indian gardens in the following extracts. Dr. King is a practical as well as a Scientific Director.

"In spite of the heavy rainfall, the number of cinchona plants, destroyed by landslips in the Beugal Government's plantations was less last year than in previous years of smaller rainfall, and no damage was done by hail. The outturn of the factory, which is generally regulated by the demand, was four thousand pounds of cinchona febrifuga and the same number of pounds of sulphate of quinine, as against six thousand five hundred, and one thousand eight hundred pounds respectively in the previous years. The revenue derived was a little under one lakh and twenty thousand rupees, and the net profit showed seventeen thousand rupees, a result which may be considered as satisfactory and quite sufficient. Profit is no object with Government. It desires to secure a cheap remedy for fever for use of the people. The Lieutenant-Governor has discovered by personal enquiry that many dispensaries instead of buying the drug direct from Dr. King at one rupee per ounce, purchase from private stores at Rs 2 and Rs 4 per ounce which, as the resolution rightly says, 'is an obvious absurdity.'

"The Botanical Gardens maintained by the North-West Provinces Government at Sabarunpore and Mnssoorie afford an excellent example of the public advantage of such institutions. As regards cost, it appears that the gardens are virtually self-supporting. The expenses last year amounted to Rs20,143-14-10. On the credit side we have cash receipts to the extent of Rs16,323, and the Director-General of Agriculture remarks that allowing for the seeds and plant distributed to soldiers' gardens and supplied to public gardens and societies in addition to the direct saving to Government on drugs grown and manufactured for the Medical Department, there would be a balance in favour of the credit over the debit side of the account. On the benefits to agriculture and the prosperity of a province mainly dependent on the cultivation of the soil, many proofs could be quoted. Mr. Holderness says generally: 'The beneficial effect of the Sabarunpore and Lucknow Gardens on horticulture in Upper India is capable of easy verification by anyone who moves about the country and notes the progress which gardening and fruit growing are making among the native community.'" The extract that refers to cinchona is especially interesting. Here are we, with large reserves of cinchona, sending ultimately our produce to England to the manufacturers there, who will buy it for a mere nothing; our Government buying their trifling quantities at a high figure, when it might, as the Indian Government does, buy cinchona on the spot and manufacture it.

CEYLON TEA FUND COMMITTEE.—Mr. Roberts, I think, was quite right to bring to the notice of the Committee what some bystanders are suggesting to the detriment of the Standing Tea Fund Committee and the new Tea Company. The Tea Fund Committee had a good answer to give such scoundrels.

TEA AT TENPENCE and low rates of exchange pays, but the genius who averages 5½d is not the one to lead us on to victory.

COFFEE is falling in a most extraordinary way, which points to its being an article for the speculator, so I fancy there will be soon a sharp rise, more especially for Ceylon.

THESE INVENTORS OF TEA DISEASES should be deported at the expense of the Colony. Let the Governor use one of his Prunes and Prismatic measures—say Promptitude—to get Dr. Trimon's answer to those Indian Quacks.

NATIVE TEAMEN of our acquaintance inform us that the profits they have made out of common tea will not go half way towards covering the losses they sustained on their finest grades. They are greatly put out this season to find that the high district teas fetch such a comparatively small advance on those from the low districts, and declare that the business in fine kinds is not worth following. They assure us emphatically that next season's supply of Congou will show a further falling off of fully 50,000 chests.—*Foochow Echo*, Sept. 26th.

AN INTERESTING TOUR of the principal botanic gardens in the world was recently made by an American botanist, in order to procure from these establishments specimens of the useful products of the vegetable kingdom for the University Museum at Cambridge, Massachusetts. The botanist visited on his tour Gonon, Ceylon, Adelaide, Dunedin, Sydney, Brisbane, Java, Singapore, Saigon, Hong Kong, Shanghai, and Tokio. The traveller was particularly struck with the Botanic Gardens in Ceylon. Plants from Australia are quite at home with those of the West Indies, Japan, or England. "Once for all," says the American, "it may be said that botanists are made welcome (to these gardens) in every way, finding every facility for carrying on systematic work."—*L. and C. Express*.

TEA AND EXCHANGE.

In reviewing the sea-borne trade and navigation of Bengal a few months ago, Mr. Scobell-Armstrong referred briefly to the question in how far the tea industry is affected by a fluctuating exchange. In his opinion an alteration in the relative value of gold and silver cannot in the long run either stimulate or check the production of tea in India, since the change neither affects the desire for tea on the part of the consumers nor reduces the amount of goods which he is willing to give in exchange for it. Mr. Armstrong illustrated this argument by a sketch of what in his opinion would be the effect if silver should rise, say, to 18 9d and stay there or thereabouts. In the first place, he said, the rupee price would fall, but there could be no immediate increase in the price of tea, since the amount of tea put on the London market would for some time remain as great as ever. If the depression became sufficient to check production and the extension of gardens, "there would no doubt be some rise in sterling price, but it would only be for a time" assuming, of course, that the rise in silver were due to its becoming dearer. If it were due to gold becoming cheaper, gold prices would rise at once and to the full amount and there would be no depression at all. In the event then, that silver itself had become dearer, there would, Mr. Armstrong admits, be a depression in the tea industry. "Profits," he says, "would not be so great for a time," but the tea planters would eventually reduce their outgoings, for since their rupees would have risen in value they might fairly claim to pay less of them. When the planter's outgoings had been reduced in proportion to the new value of the rupee, his profits, Mr. Armstrong contends, would be as large as ever. With a sudden rise in the value of the rupee the depression would be severe, but the adjustment would be effected sooner; with a slight rise the depression would be slight, but it would be longer before it disappeared. In any case, however, the final adjustment would be only a matter of time.

In an official resolution published, on Wednesday, Mr. Armstrong's argument is examined both from a practical and theoretical point of view. In the former respect it is contended that the explanation suggested by the Collector of Customs does not agree with the tea-planters' experience. "It is true," the resolution admits, "that he will pay less for machinery, European stores and other articles purchased in England. It is also true that, as all tea-growing countries use a silver currency, the tea planter is free from the special disadvantages which hamper the Indian wheat-grower in his attempt to compete with rivals in gold-using countries. As, however, the bulk of the planter's expenditure is incurred in India, where fluctuation in the value of the rupee is comparatively inconsiderable, he cannot protect himself, as Mr. Scobell Armstrong suggests, by reducing his payments for wages and articles produced locally. It would seem, then, that "the gardens which fail year after year to gain the normal profit of capital must sooner or later go out of cultivation, and only those will survive in which the cost of production is cheapest. "The price of tea in London is the resultant of so many causes that it cannot be supposed that the contraction of output caused by the closure of the more expensive gardens will so reduce the total supply as to cause the price of tea to rise to a figure at which it will pay to re-open and work them." The fallacy, indeed, of Mr. Armstrong's argument lies in the idea that the expenses of a tea garden can be automatically adjusted with the rise and fall of Exchange. Even if the suggestion were correct in theory it would still be opposed to all the results of practical experience.—*Calcutta Englishman*.

THE JAVA BUDGET.

(FROM OUR AMSTERDAM CORRESPONDENT.)

The Java Budget for 1892 has been introduced in the Second Chamber of the States-General. It appears that the profit balance of 1889 amounts to f. 1,222,164 more than estimated, the total profit being thus f. 2,116,738. The service of 1890 will probably exhibit

a profit of f.8,048,775, or f.3,500,000 more than the estimate. As regards 1891 it is expected that the estimated deficit of f.23,333,333 will be about f.16,500,000. The final figures for the Budget for 1892 are as follows: Expenditure in Holland, f.25,573,217; expenditure in India, f.110,780,123—or total, f.136,353,340. The revenue in Holland is f.21,751,268, in India f.97,793,415—or total, f.119,544,713, the Budget closing thus with a deficit of f.16,803,627. When compared with 1891 the revenue is estimated at f.5,697,368 more, and the expenditure f.825,502 less. The following revenue is estimated higher:—The sale of coffee, f.1,460,000; the sale of tin, f.395,000; the opium farm, f.1,340,000; the sale of salt, f.305,000; the working of railways, f.697,000; post and telegraph, f.130,000; banking business, f.327,400; import and export duties, f.540,000; excise, f.382,000; license duty and other duties, f.327,000; and revenue of the Departments of War and Navy f.146,000; the revenue from the trade tax is estimated at f.250,000 lower, and that from the sugar cultivation f.325,000 less. The increase of the revenue is totally absorbed by the expenditure, chiefly by that of the department of home Government, in consequence of the lower estimated purchase of coffee. The deficit on the Budget is caused by an amount of f.3,500,000 for the purchase of 190,000 piculs coffee more than the quantity estimated for sale, which amount will be an advance in favour of following years. On the other hand the production of tin is estimated at 80,000 piculs, while the quantity to be sold will be 100,000 piculs. The price of purchase for those 20,000 piculs more is about f.500,000 by which the deficit is to be increased in order to know the exact amount of it, which will be thus:—f.13,800,000 or f.14,000,000 in case the export duty on sugar remains suspended. An amount of f.7,335,000 is proposed for the construction of harbour works near Batavia, and for Government railways and f.3,105,000 for new irrigation works. Against the extraordinary expenditure there appears some extraordinary revenue, the difference of which is f.9,819,000. If this amount is deducted from the deficit it is reduced to f.3,981,000 on the ordinary expenditure. It is not improbable that the Budget for 1892 will close later on with a less unfavourable final figure, but the minister will not agree with the opinion that this Budget is to be considered as not being a normal one. The revenue from coffee is estimated for 1892 at f.13,510,000, but it is not to be expected that the average of following years will be larger. Although an increase of revenue is probable out of the Billiton Mines and the Ombilion Coalfields, a decrease of the production of the Banca Mines is anticipated, and in the event of larger proceeds from the license duty there will be on the other hand an increase of other expenditure, such as remunerations, pensions &c. The Minister therefore considers the condition of the finances as being unsatisfactory, and he states that India should independently provide for its finances for this reason an urgent necessity. In order to arrive at this an economical administration is required, for which efforts will be made, and an inquiry will take place into the whole organisation of the Government. Besides this measure the revenue is to be increased, for which proposals will be made shortly. Moreover, the strengthening of the productive power in India must be taken up, and in connection herewith the Minister proposes already an amount of f.3,105,000 for irrigation works, to which he intends to add to commence with the construction of the works for the irrigation of the Solo Valley. As soon as he has received information he will propose the improvement of the means of communication. Going on to the items of the Budget the Minister asks f. 600,000 for the construction and equipment of two fast steamers for an effective restraint of the opium smuggling. The question what ought to be done with regard to opium will be considered by the Java Government in connection with the report of Mr. Groccoody. In anticipation of advices from Java an appropriate packing of the quantities asked by the consumers is wanted, the great importance of which, in connection with the preparation by the Government is acknowledged, as well by the promoters as the opponents of the farm system. As to the Govern-

ment's coffee cultivation, the Minister has followed in this Budget the existing regulation, but it is his intention to make a proposal, as soon as the advices from India upon the report of the States Commission have been published. An amount of f. 756,700 is proposed for waterworks at the east side of Sourabaya; f. 630,000 for a dock in the harbour of Tandjong Priok; f. 6,565,100 for the construction of railroads, of which f. 3,772,500 for the line Wurang-Bandoug-Tjilatjap; f. 225,000 are required for the completion of vessels for the Indian Navy, while f. 1,100,000 are asked for the construction of two other vessels for the Military Navy in India. The condition of the material of the Indian War Navy, in connection with the necessity to blockade a part of the coast of Aceh, does not permit of any delay for the decision upon the report of the States Commission. The quantity of coffee to be sold in 1892 is estimated at 235,000 piculs, the probable proceeds of which will be about c. 45 per $\frac{1}{2}$ kilo. As the temporary freedom of export duty on sugar will expire on June 1st, 1892, the proceeds are estimated at f. 300,000 more than the proceeds in 1890. The question is still considered whether it is not necessary in the present circumstances, to propose a prolongation of the suspension for one year. In the meantime another pending question could then be solved, whether it is possible to introduce another tax, which would burden not so heavily, but compensate the loss suffered by the Exchequer.—*L. and C. Express.*

THE TEA FUND COMMITTEE AND THE PROSECUTION OF FRAUDULENT TEA DEALERS.—We have been asked to contradict the erroneous report that has got about to the effect that the Tea Fund Committee will not sanction further tea prosecutions. It appears to have originated through some careless reading of the minutes of a former Committee meeting. The Committee declined to advise any further prosecution at present—a very different thing—and will no doubt be ready to prosecute again, whenever good reason exists. Such prosecutions are always expensive things, and only to be indulged in on good cause shown, but this false rumour may do harm if uncontradicted.

THE QUININE SYNDICATE RUMOURS.—The rumblings of the recent outbreak still reverberate through the pages of the *Indische Mercuur*. Mr. Kessler, a Java planter now in Holland, gives it as his opinion that the way to establish a successful combination is for the planters to place the sales of all their bark into the hands of a central body in Europe, which shall have the control of the analyses, in order to avoid the uncertainty which now attaches to these, and which often causes two lots of the same parcel of bark to be sold at 25 per cent difference in price because the analyses have been made by different people. The central body would also fix the total quantity of bark to be harvested by estates forming the syndicate, and it should agree to sell no bark below a unit of say, 12 cents, or about 2½d per lb. which is fully double the present price. A joint committee of the two great planters' associations in Java would be asked to lay down after personal inspections the quota which each individual plantation should contribute to the total amount fixed by the central body. The combination, it is thought, would be sufficiently powerful to leave the two or three estates now making direct shipments to the Brunswick works out of account, the more so as those estates would be sure to join the syndicate as soon as they regained their liberty. If no combination is effected, Mr. Kessler foresees a further considerable decline in the price of bark, to be followed either by the wholesale uprooting of plantations or by the gradual purchase at rubbish prices of most of the cinchona estates by some individual financier, who will in this manner succeed in obtaining ultimate control of the market.—*Chemist and Druggist*, Sept. 26th.

GRASS OILS AND THEIR VARIETIES.

SUMMARISED BY J. CH. SAWER, F.L.S.

Of the genus of grasses belonging to the tribe *Andropogoneae* about twenty-five species are met with in India; of these, four or five are of commercial interest as yielding the oils known as "grass oils."

The greatest confusion has existed in the identification of the plants yielding the essential oils from this genus, and much uncertainty yet appears to exist in Europe in the assignment of each oil to its proper botanical source—that is to say, in the identification of nearly-related plants which afford distinct oils known commercially under various names in London, Paris, and the East. The trade-names in London of the four principal oils being known in Egypt, in Turkey, and in India under such a great variety of names, and the plants they are derived from being known in the various provinces of India under such a quantity of local dialects, it is not surprising that errors creep into the literature of a subject so difficult as that of the identification of the plants which yield the four oils known on the London market as "citronella," "lemon-grass," "ginger-grass," and "vetiver." Had I not personally known one of the largest growers and distillers at Singapore, who was as well versed in the Malay and Indian dialects as he was in the cultivation of the plants, I might have been led by text-books to believe in the existence of a great number of plants yielding various oils under many names.

The European and vernacular names are very numerous, but the oils are four (unless rectified or adulterated oils be counted), and the plants yielding them are four (unless a sub-genus, *Cymbopogon*, or varieties somewhat modified by cultivation, be counted).

There are writers who refer back to Dioscorides—even to Jeremiah—but those Ancients mixed up many plants under one poetical name, and led us Moderns into much confusion and dispute (instance, "Spikenard"). Their writings, in language not ever rich in botanical terms, are misty and abrupt in expressions, and they have been mangled in translation and re-translation. To Watt's "Dictionary of the Economic Plants of India," published in Calcutta 1839—a very valuable work philologically, botanically, and commercially—I am principally indebted for the vernacular names given in this summary. I only quote a few, as a complete list would be too lengthy.

There certainly is great difficulty of expressing by any combination of the Roman characters or by accentuation the guttural pronunciation, peculiar aspiration, &c., of Arabic, or of the languages and dialects of the East; possibly they might be more easily rendered in German.

A museum-specimen of essential oil should be distilled by the exhibitor himself, as all Oriental oils are adulterated; it should be accompanied by a dried specimen of the plant taken when in flower, a sample of the root, and a drawing of the living plant, also a description of the aspect of the place where found, and its exact local name written in Oriental characters—then, in London, we know it.

However, to summarise on the evidence at present available, the commercial oils derived from the five plants are as follows:—

1. OIL OF CITRONELLA.—This is the *Andropogon nardus* of Linnæus, and is figured in Bentley and Trimen's "Medicinal Plants," tab 297. Synonyms: *A. flexuosus* and *A. coloratus*, Nees; *A. Martini*, Thwaites ("Ency. Ceylon Plants," 361); *Cymbopogon nardus*, Linn. (Pharmacopœia of India). In Kinnel's "Report of the Products Exhibited at the 1862 Exhibition," he wrongly assigns citronella to *A. citratus*; and he is wrong in his names of three out of four of the grasses.

This grass is very common in the plains of the Punjab and North-West Provinces. It is extensively cultivated in Ceylon and at Singapore for the manufacture of the oil from its leaves, and it is abundant at Travancore. As cultivated in Ceylon on Winter's estate near Jalli,* it often attains a height of 6 or 8 feet. The oil from this estate is considered as fine as, or finer than, that from Singapore.†

* Gallo!—Ed. T. A.

† In the London market "Winter's" oils rank in value somewhat below "Fisher's" Singapore oils.—Ed. C. & D.

In Ceylon the citronella grass is raised from seed and planted like guinea-grass. It yields two or three crops a year. (a) It is distinguished from the other species by its peculiar reddish tint, short spikes, and narrow leaves. The pure oil is thin, almost colourless, or of a pale greenish-yellow, and strongly aromatic. It is to this oil that the well-known odour of "honey-soap" is due. Very interesting details of recent researches in the chemistry of citronella are detailed by Mr. Dodge, (b) mention being also made of Professor Pluckiger's discovery of the peculiar property possessed by this oil, and that of *A. citratus*, of solidifying, with evolution of heat, when shaken for ten minutes with a saturated solution of sodium bisulphite. It seems probable that the essential oil from a given plant may not only vary in density and boiling-point according to the age of the oil, but according to the age of the plant, the season when gathered, and the soil in which it was grown.

It is well known to the trade that in the East citronella is largely adulterated with kerosene, large quantities of which are imported in Ceylon, in great excess of the requirements for illuminating purposes. Samples have been found to contain 18 per cent. of this adulterant. Many common fixed oils are also used.

2. OIL OF LEMON-GRASS.—This is derived from the *A. citratus* of De Candolle. Syn., *A. schœnanthus*, Wallich, Plant. As. Rat. III., tab. 280.

The vernacular names, "Gandha-benâ" (Bengal) and "Maltrinukug-blüstrimung" (Sanskrit), are, by Roxburgh, (c) given to a plant he describes as *A. schœnanthus*, Linn. This description may be referable to *A. citratus*, De C., but it seems to agree equally well with the *A. Laniger* of Desfontaines.

It is a large, coarse, glaucous grass found under cultivation in various islands of the Eastern Archipelago, and in gardens over an extensive tract of country in India. It very rarely flowers, but Dr. Dymock, of Bombay, states that he has seen it in flower more than once. It is largely cultivated in Ceylon and Singapore for the odoriferous oil distilled from the leaves, which is called lemon-grass, verberna oil, or Indian melissa oil.

The oil is employed in Europe as an ingredient in perfumes, very considerable quantities being used in the manufacture of candle Cologne. It is also used for adulterating the so-called "true verberna oil" obtained from the *Lippia citriodora* in Spain. This plant is sometimes called *Aloysia citriodora*, and it is certainly not a verberna plant at all. Oil of lemon-grass is said to be called *Sireh* in Java, but that word may apply to the oil of *Tetranthera citrata*, a Javanese plant of similar odour. This "verberna" odour is also developed in *Eucalyptus staigeriana*, *Eucalyptus citriodora*, and *Bachkovia citriodora*, Australian plants, from which oils are distilled.

3. VETIVER OR CUS-CUS.—This is the root of the *Andropogon muricatus*, Retz. Syn. *A. squarrosus*, Linn.; *Vetiveria odorata*, Virey; *Anotheron muricatum*, Retz; *Kaphis muricatus*, Nees; *Phalaris sicanioides*, Linn.

There is a verse in the Sanskrit language composed of nine words, arranged in two lines, (d) purporting to be the nine names under which the plant is known; doubtless they were poetical names, as they are not to be found in the extensive list of local names recently enumerated by Watts. (e)

The roots are universally known in Bengal as "Khas" or "Khas-Khas," and in Bombay as "Khas-Khasa." It is a perennial, tufted grass, very conspicuous, tall and erect. It is very common in every part of the coast of Ceromandel, Mysore, also in Bengal and Burma, where it meets with a low, moist, rich soil, especially on the banks of water-courses. It covers large tracts of waste land in Cuttack. It inhabits the plains of the Punjab and North-West Provinces, and ascends into Kumaon, 1,000 or 2,000 feet in altitude. (f) It is also found in Mauri-

tius and the Philippino Islands, and, excepting lemon-grass, is probably the only species of the grasses under discussion occurring in the New World, being abundant in the Antilles, Porto-Rico, Jamaica, Brazil, &c.

It was observed by Virey, (g) that the word *ver* in the Hindu language means "a long, creeping root." The roots of this grass closely resemble in appearance the roots of the "Chiendent-à-balai" (*A. ischemum*, Linn.), roots which are used for making carpet-brooms, being long, thin, and creeping, with a bark of a pale yellowish brown or light tawny colour. The roots extend in a fibrous tangled mass. In the "Gazetteer of the Central Provinces" this grass is described as a nuisance to the agriculturists, as it grows on the rich soil and is very difficult to eradicate, but the "Oudh Gazetteer," III., p. 176, says—"it is generally strictly preserved, as it takes time to spread, and proprietors are averse to its being dug up for Khas." This seems to indicate a different value being put on it in the different localities within the wide range of its growth. This plant is alluded to on some copper-plate inscriptions discovered near Etawah, south-west of Agra (dated A. D. 1103 and 1174), as being one of the articles of commerce on which the Kings of Kanauj levied taxes. (a)

The leaves are inodorous. The roots have a strong, peculiar odour, somewhat like myrrh, combined with that of some flower. This odour partly disappears when the root is dried, but immediately manifests itself on the application of moisture, and is retained so tenaciously as to be perceptible after the root has even been scalded, or partly boiled; they contain a resin of a deep brown colour, having an acid taste and an odour like myrrh, a colouring matter partly soluble in water, a free acid, a salt of lime, a considerable quantity of oxide of iron, (b) and a powerful volatile oil, which is rather difficult to extract thoroughly in the ordinary way by reason of its high boiling-point and its association with the resin; this difficulty may be overcome by placing the root in a steam-jacketed still with just sufficient water to drench it, and allowing it to stand for a short time, so that the water may penetrate into the tissues. Then, by admitting steam of about 15 lbs. pressure into the jacket, the light oil (for there is a light oil of a lower boiling-point) will come over and may be collected separately, and a current of steam of 15 lb. gradually raised to 25 lb. pressure afterwards admitted into the still by a pipe at the bottom can be blown through the mass until oil ceases to drop into the receiver. Dr. Piessé, in his work on perfumes, states the yield to be 10 oz. per cwt.; but, according to Watt, (c) the yield of 100 lb. of root is only 2 oz. The crude heavy oil is very viscid, of a dark brown colour, consisting mainly of a liquid boiling at 230°-283° C. Dr. Gladstone found that the action of sodium proved this to be a mixture of two bodies, the one decomposable, the other unalterable by that metal. He states the sp. gr. at 19° 5 C. to be 1.007. (d)

The uses of vetiver in England are confined to the distillation of the oil, which commands a very high price. The oil enters into the composition of many favourite perfumes, as "Meusclino des Indes," "Marschal," "Bouquet du Roi," &c., and it is known that in India the roots are woven into fans, screens to cool the atmosphere, ornamental baskets, &c. Dr. Irvine, in his medical topography of Ajmore, mentions the oil in the preparation of shorbet. In India it enters into the composition of several cooling medicines. An aromatic bath is prepared by adding to a tub of water the following substances:—Roots of *A. maricatus*, *Pavonia odorata*, sandal-wood, and a fragrant wood called "Padma Kastha." (e) The oil is administered in 2 minims doses to check vomiting in cholera. Mixed with henzoïn, and smoked in the form of cigarettes, it relieves headache.—Watt.

4. GINGER-GRASS OIL, OR GERANIUM OIL.—This is derived from the leaves of *Andropogon schamanthus*,

Jinnâus. Syn. *A. Martini*, Roxb.; *A. nardoides*, Nees; *A. pachnodes*, Trinnins; (f) *Cymbopogon Martini*, Munro; and *A. calamus aromaticus*, Royle. (g), (h). *A. Iwarancusa*, Schultes, is identical with, or a mere form of, *A. schamanthus*, Linn.

This plant has many names in India, such as Agyaghas, Ganda-bena, Mirchia-gand, &c., fully detailed in Watt's "Dictionary of Economic Products," i. p. 249. The oil is known in commerce under a variety of names, such as: in England, ginger-grass oil, Turkish oil of geranium, Rusa-grass oil, oil of Nimar, or Nemaar. In the otto-producing districts of the Balkan it is known to Europeans as essence of geranium and oil of Palma-rosa; in India it is called Rusa-oil, Roshel, Rusa-ka-tel; in Egypt, Arabia, and Constantinople it appears under the names of Idris-Yaghi and Entreshah, names which may mislead to the belief in a variety of oils produced from several plants. These names seem to be mostly of modern origin, and to indicate the use to which the oil is put. As pointed out by the authors of the "Pharmacographia," these names look very like a corruption from *Rose-oil*, the more so since the principal consumption is as an adulterant of otto of rose. It is curious, however, that, as stated by Dr. Dymock, the Indian distillers and dealers know nothing of this use. The name "geranium-oil" has caused much confusion with the true geranium-oil, derived from various species of *Pelargonium* (which will be afterwards described), and has apparently come into existence from the fact that the so-called "geranium grass" oil is used to adulterate the true geranium oil, which, in its turn, is used to adulterate the otto of rose. The grass is found growing wild in large tracts in the northern and eastern provinces, particularly in the north-west provinces of the Punjab; it is abundant everywhere in the Deccan, in Central India, and is cultivated in Kashmir in localities formerly devoted to the rose. Dr. Roxburgh states that he first noticed the plant as grown from seeds forwarded to him by General Martin, collected at Balaghat during the last war with Tippoo Sultan.

The grass flowers in October and November, and is then fit for cutting. Dr. Dymock says that 373 lb. of grass received from Khandesh and submitted to distillation under his own superintendence in Bombay yielded 1 lb. 5½ oz. of oil.

The "Bombay Gazetteer," III., page 251, gives an interesting account of the manner in which Rusa oil used to be prepared at Panch Mihalas:—"The grass-oil from the large-bladed aromatic grass known as Roisa, which used to grow over large estates of waste land, was sold in considerable quantities at 4 rupees per lb., and used freely as a remedy in rheumatism. . . . The oil was extracted by distillation; a rough stone oven was built by the side of a stream, and in it a large metal cauldron was placed, filled with bundles of grass and water; a wooden lid was put on, and sealed with a plaster of ground pulse. Through a hole in the lid one end of a hollow bamboo was thrust, and the other end passed into a smaller metal vessel securely fixed under water in the bed of the stream. The oven was then heated, and the vapour passing through the hollow bamboo was, by the coldness of the smaller vessel, condensed."

Apparently the first mention of the oil was by Maxwell, in 1825 (i); but it is only within comparatively recent times that the oil has become an article of commercial value.

From the fact that the largest supplies of Rusa oil are obtained from the Nimar district, at Khandesh, Bombay Presidency, the oil has come to bear the commercial name of Nimar, Nimaar, and Namar. Dr. Dymock, describing the manufacture in this district, states that an iron still is used, and only a very small quantity of water added to the grass; when the still is carelessly worked the grass burns, and communicates a dark colour to the oil, which should be a pale-sherry colour when good. Its odour at first recalls that of the rose, but this sensation is almost

immediately followed by a strong odour of lemon or citron. By rectification it is rendered perfectly colourless, and the odour of lemon is less marked. It is exported from Bombay to the Red Sea ports (chiefly to Jeddah), to Constantinople, Trieste, and London. Before being sent to Turkey, which absorbs the great bulk of it, large quantities are sent to Paris for rectification. In Turkey it is subjected to special treatment, which appears to render it more fit to mix with otto of rose without betraying its odour. This consists in shaking it with water acidulated with lemon juice, and then exposing it to the sun and air. By this process it loses its penetrating after-smell, and acquires a pale-straw colour. This process was described by Mr. Baur, of Constantinople. (j) As found on the London market, it varies greatly in quality. A distinction is often made commercially between oil of Palma Rosa and essence of Indian geranium, although both are identical products of the same plant. The first is probably only a superior quality, or contains a small addition of oil of pelargonium.

For some years past an essence of geranium has been received from Java, possessing all the characters of Palma Rosa, but its exact botanical origin and method of production are unknown.

An oil termed "Huile Essentielle de Pataque Malgache" has been introduced from the island of Reunion, described as distilled from *Andropogon fragrans*, with an odour identical with Indian ginger-grass oil. (k)

Dr. Blondel, in his elaborate work on "the odorous principle of the rose," (l) states that the oil known as essence of geranium (and it may be remarked, in passing, that he wrongly attributes this oil to the *A. schwanthus*, of Wallich) is largely adulterated in India, in the districts where it is distilled, frequently to the extent of 20 per cent., with the oils of gurjun and coker-nut, and that on its arrival in Europe it is submitted to another adulteration with turpentine.

Dr. Dymock states that he has been assured by the Bombay dealers that all the geranium oil of commerce is more or less adulterated, and a comparison of the commercial article with some oil distilled by himself supported the assertion. The distillers are said to be regularly supplied with turpentine from Bombay. It appears that the Kandesh Bishr oil is also adulterated with ground-nut, rape, and linseed oils. With turpentine and ground-nut the resulting turpidity passes off in a day or two; hence they are preferred, and turpentine is chiefly used because it cannot be detected by the evaporation test. Consequently I aver that whatever tests be applied to otto of rose, in presence of such wholesale adulteration of its main adulterants, it is hardly possible to put reliance on such tests. The difficulty of obtaining the otto pure is still increased by the chance of its being even further manipulated in Paris, or in London, with sandal-wood oil, cedar-wood oil, castor oil, stearoptene, and alcohol.

The addition of geranium oil to otto of rose was formerly only made in Constantinople, but now the mixing takes place at the seat of the manufacture of the otto. It is said that in many places the roses are sprinkled with it before being placed in the still. This probably makes a more perfect "blend."

Although the introduction of geranium oil into Bulgaria is now forbidden by the Government, it is still brought in secretly by Jews and Greeks.

If any large dealer or wholesale merchant in London were to establish a rose-farm and good stills in a locality tainted with this Eastern fraud (and such localities might be found near Damascus, or in Tunis, where the climate and soil are eminently suitable to the growth of the rose), it is possible that under competent and honest English management, a business could be constructed which would result in large profit. I am not aware that such has been attempted or suggested yet.

A perfectly pure otto of rose should congeal in ten minutes, at a temperature of 14° to 16° R. The oil of ginger-grass does not solidify by cold, hence the Turkish merchants prefer an otto from mountainous

districts, rich in stearoptene, and, therefore, capable of bearing a larger amount of adulterant without interfering with its tendency to crystallise when the sample is placed in cold water. Mr. Baur's paper, above referred to, details these methods of testing the otto.

Medicinally, this oil is used as a liniment in chronic rheumatism and neuralgia, and it is believed to have the property of curing baldness.

5. CAMEL-GRASS.—This aromatic grass seems to be very little known in England by name, and its essential oil does not appear to be known at all. Botanically it is *Andropogon Lanigerum* of Desfontaines. It is identical with *Favum camelorum* and *Juncus odoratus*. It has been termed *Cymbopogon Laniger*, and it partly agrees with Roxburgh's description of *A. Isarancusa*. It has long been known to pharmacists in the East as *Herba schwanthus*, and is figured by Pomet in his "Histoire des Drogues" as "sqnonantho." (m)

In Bengal it is known as "Ibharankusha," in the North-Western Provinces (amongst other names) as "Gangli-ban." The name in Bombay and Arabia (for the culms of the plant, with or without a portion of the root) is "Izkhir." This name, as given in the best lexicons, is derived from the same Arabic root which furnishes the derivative "Zakhira," a common term in India for stored-up forage &c. The name *Favum camelorum* signifies its use as a forage for camels. It is a native of Arabia, growing plentifully in the desert and in the hot, arid regions of Algeria. The Arabians call it "Helsi Meceavi" and "Idhir Mecchi." It is said that in the deserts between Syria and Egypt it is the only grass eaten by camels. This plant has a wide distribution, but is not cultivated. It is found growing on the lower Himalayan tracts and in Thibet at an altitude of 11,000 feet, extending through the plains of the North-West Provinces to Sind. Roxburgh says it grows in large tufts, each tuft composed of a number of plants adhering together by the roots. This description corresponds with Pomet's figure alluded to above. It is common about Kurrachee, and is used as a perfume by the natives.

Lemery, commenting on Pomet, says that this "*Favum camelorum* is a kind of fragrant rush, or grass, growing plentifully in Arabia Felix at the foot of Mount Libanus, where it serves for fodder and litter for the camels. The stalk is about a foot high, divided into several hard stems, of the size, figure, and colour of barley-straw, being much smaller towards the top. The leaves are about half a foot long, narrow, rough, pointed, of a pale green colour. The flowers growing on the top are ranged in double order, small, hairy, or a carnation colour. . . . all the plant, and particularly the flower, is of a strong smell and bitter taste." This plant is also figured in Plukenet's "Phytographia," 1691, tab. 109, fig. 1.

"ALGERIAN GERANIUM OIL" is derived from three species of *Pelargonium*:—The *P. odoratissimum* (Willdenow) (n); the *P. capitatum* (Aiton) (o); and *P. roseum* (Willdenow) (p)—a variety of *P. radula*, (Aiton). (q).

These plants are cultivated in open fields in many parts of Algeria—notably at La Trappe de Stanel, near the Bay of Sidi Ferruch, at Castiglione, at Sahel, in the good red soil consisting of a decomposition of micaceous schists, (r) at Boufarik, at Blidah, at Grand Cherakas and at Guyoville, in the environs of Constantine, and in the plains of Metidja, close to Algiers. The average production of Algeria is about 6,000 kilos; the price per kilo, varies from 45f. to 60f., according to quality and yield. Originally the plants were cultivated on dry, arid slopes, where they were stunted in growth, but yielded a perfume of great delicacy. Now, on the contrary, the plantations are established on low-lying and rather humid soil, which yields three crops annually instead of one. By a system of irrigation which flood the plantations, the proprietors force the growth of the plant to a

l Blondel's *Les Produits Odorants des Rosiers*. 1889.

height of about 30 inches, and nearly an inch thickness in the stem. Under these conditions the oil is produced in much greater abundance, but the quality is sensibly inferior.

In my recent article on "Lavender" I pointed out the immediate effect of a moist soil on the secretions of a plant which prefers a dry soil. The above remarks, which I translate from Blondel, not only confirm the observations of my own short experience, but they are in accord with the observations of Linnæus.

This irrigation process is now so general that for one hectare of land cultivated "dry," 200 hectares will be found "irrigated." The very superior product of the "dry" method is rarely sold separately, but is generally mixed with common oil (called "Geranium irriguè") to ameliorate the quality.

Ordinary stills are used for the distillation, which is carried on during the whole time of each harvest. It is estimated that 500 kilos. of the plant yield 1 kilo. of oil. "The plant is gathered a little before the opening of its flowers, when the lemon-like odour which it at first possesses gives place to the odour of rose—this critical point is recognisable by the leaves beginning to turn yellow. The oil is formed entirely in the leaves and all the green parts of the plant, the petals yielding no odorous product whatever, but in order to waste no time in detaching the flowers they are put in with the branches." The odour which may be thought to be perceived in the flower is simply due to the secreting organs in the calyx and peduncle. The pelargonium is also cultivated and distilled in other countries: in Spain (near Valencia), Italy, Corsica, the Island of Bourbon, and in Provence. The Spanish oil is considered the finest (probably owing to the fact that the plantations are not "irrigated"); the plant which produces it is not known with certainty, but it is said to be the same as the Algerian plant. The oil from Provence ranks equally as regards quality with the Spanish; a "superfine" oil is also manufactured in Provence by adding rose petals to the still. The Corsican oil is only exported in small quantities, but the Bourbon production annually increases in importance. Oil of pelargonium should be perfectly soluble in all proportions in alcohol of 70 per cent.^(s) There are other pelargoniums of a rose-odour, as *P. graveolens*, Aiton.^(t) The *Rhus aromatica*, Aiton, or fragrant Sumach, has been described by Harper (in *American Journal of Pharmacy*) as possessing an odour similar to rose geranium. An artificial oil of pelargonium was produced some years ago in London by a German chemist, but the method of production was not, that I am aware of, disclosed. The discoverer presented me with a sample, which now, after about twelve years, compares very favourably with a sample of Provence oil of pelargonium put aside with it. The first has developed a faint odour of chloroform; the second has turned rancid, probably owing to decomposition of a fixed oil adulterated with it.

There are several artificially prepared liquids known in chemistry, possessing an odour somewhat like pelargonium and rose, such as citronellyl alcohol, salicylate of ammonium, and benzoate of phenyl. These compounds are somewhat troublesome to make, and may be more expensive than the natural oils; also they may be unstable and apt to decompose by admixture with other bodies for perfumery purposes; but yet they are suggestive, and an exact knowledge of the composition of the natural oils may lead up to a method of producing them synthetically.—*Chemist and Druggist*.

IRRIGATION COLONIES IN AUSTRALIA.

BY MR. C. G. PALMER, EXECUTIVE ENGINEER,
N.-W. P., IRRIGATION DEPARTMENT.

I have been for years on the look out for an opening in a good climate where my sons can be given a good

start, and I may spend the evening of life in profitable light work and pleasant surroundings. By the advice of an eminent hydraulic engineer, who has a successful record in both Australia and Europe, I went up the river Murray and looked at the Chaffey irrigation colonies recently started at Mildura (in Victoria) and Renmark (in South Australia). My friend is a man of very wide experience, and was greatly impressed with the material and social advantages obtained by settlers in those colonies. I went up a sceptic and inclined to look upon the whole thing as a gigantic swindle, but careful examination on the spot convinced me, as it convinced my friend, that the scheme is sound in every detail, and those who join in it will get high profits and a most pleasant social life.

Messrs. Chaffey (George and W. B.) are Canadians who emigrated to the States many years ago; they gained experience and made money in the irrigation colony of Riverside, S. California, then founded and made more money in the irrigation colony of Etiwanda, and again in Ontario, both in San Bernardino, S. California. While working Ontario their attention was invited to Australia, and they came out here, prospected the country, obtained large concessions from the Governments of Victoria and South Australia, and started Mildura in 1887 and Renmark in 1889. Both colonies are on the Murray, the area conceded for each settlement amounts to 250,000 acres, of which about 170,000 is irrigable in each case; the colonies are within 250 miles of the sea in a direct line, situated in south latitude 34½, and have a very large proportion of exceedingly rich land most suitable for irrigation. The rainfall is as a rule just under 10 inches. The climate is absolutely charming for nine months, and hot for three months; but the heat is dry and invigorating, and at its worst is like the early hot weather of the N.-W. P. in April. Settlers there are perfectly satisfied with their climate, and go about in straw and felt hats in their hottest weather. Here, as elsewhere in Southern Australia, the heat makes itself felt, but does no injury, and the sun does not penetrate as it does in India.

The schemes are now made into limited companies, in which Messrs. Chaffey have a preponderance of power, and manage all affairs in consultation with a board of directors. The method worked on is to lay out a thousand-acre township of one-eighth acre blocks, and around it a ring of 2½-acre villa sites, and then lay out the remainder of the country in 10-acre fruit blocks; every fruit block has road frontage of 660 links (435½ feet) and depth of 1,515 links (1,000 feet). Two main avenues are laid out and numerous roads; pumping engines of enormous power erected, canals and distributaries or pipes laid everywhere, and as soon as any land is sold water is brought up to the highest corner of every 10-acre block, or laid on in pipes to every township and villa block. The company then offers the whole for sale, the township lots at £25 each, the villa sites at £100 each, the 10-acre fruit blocks at £200 per block, less 2½ per cent for cash down. The township lots and villa sites have a separate house supply water-service; the fruit blocks have irrigation water-supply pumping plant on a very large scale. Township and villa lots are nearly all sold; they carry with them shares in their own water supply plant. Fruit blocks are for sale in large numbers. A purchaser may buy one block, or up to eight blocks; but not less than one block nor more than eight can be sold to one person. Of course a man may buy eight blocks for himself and eight more for each member of his family, but it would not pay him to do so, because no method has yet been found of profitably carrying on *intense culture* on a large scale. In practice 40 acres is about the area a man can really work to the best profit. Two partners can buy a single block and divide it. If a man has sons coming on he can profitably take 80 acres or more.

Ample water rights have been secured from the Governments, and the irrigation work of each colony is thrown into the form of Irrigation Companies. Messrs. Chaffey erect pumps and all plant and perform the work, but each buyer of land receives one fully paid-up share in his Irrigation Company (Mildura Irrigation Company or Renmark Irrigation Company)

^s Jailard *Journal de Pharm.*, xxvii. p. 205.

^t L'Heritier's *Geraniologia*, t. 17.

with each acre of land he purchases, and he becomes owner of the plant to that extent. These shares can never afterwards be separated from the land. In process of time the whole management will fall into the hands of the settlers; till then Messrs. Chaffey manage the irrigation. They have already put up about the biggest pumping plant in the world at Mildura, and are lifting their water at a cost of about a penny per 1,000 cubic feet per 40 feet lift. The present annual water rate is 6 shillings per acre occupied, and it will probably not exceed 10 shilling at any time. With each acre sold there goes a share in the Irrigation Company, and to each share is attached the liability to water rate, so that a buyer on speculation may leave his land idle, if he so wishes, but he pays the annual water-rate of 6 shillings whether the land is idle or cultivated; this does not pay the mere speculator.

The Company is making canals, roads and bridges, has put up foundries and workshops; at Mildura it has commenced an Agricultural College, which the Government concession binds it to endow with one-fiftieth of all the irrigated land; the Renmark College will follow very soon. It has imported powerful machinery. A canning and raisin drying and packing factory is already started at Mildura; another will follow at Renmark. Electric lighting and telephones are in use. Telegraphic communication is established with both Melbourne and Adelaide. Special freights are already obtainable by the colonies, and when they are fairly developed they will be able to charter their own fleets and trains.

The Messrs. Chaffey have imported skilled irrigator, fruit canners, raisin finishers, machinery, and packers from California. There are enormous nurseries of vines, prunes, zante currants, apricots, olives, &c., already established. The mass of their combined products will give the settlers an enormous advantage in marketing, in freights and cost of handling; the finishing and packing under skilled supervision with the best appliances will give them the first place in every market they enter. * * * *

Thus it is that the purchaser buys not only rich land and all its irrigation plant, but he buys with it good roads and every advantage in preparing and marketing his product. He reaps the rewards of a pioneer and does not suffer the solitude, the hardships, the painful burden of purely individual labour which beset the ordinary pioneer. He may earn money elsewhere while his orchard or vineyard is growing. On the other hand, the promoters concentrate all the work in a comparatively small area, and can do everything very economically, and probably spend under £11 an acre on the land; the remainder of the value is given by their organisation, their careful planning and unremitting work. The Messrs. Chaffey are singularly capable men, as engineers, as financiers, as organisers they are hard to beat; the Californian irrigation colonies founded by them at Etiwanda and Ontario have been conspicuously successful, even in that country of irrigation colonies, and if they do make £6 an acre by it they not only thoroughly earn the money, but also help others to make a great deal more than that. And mark this; their initial expenses are enormous; for instance they have already expended quite £100,000 on irrigation plant alone at Mildura, and these cannot be recouped if much of the land remains unsold; they *must*, therefore, make it pay the purchaser, and it is to their interest to add every material and social attraction in order to quicken the stream of settlers, for the faster they come in the sooner is the return of money spent; they are therefore ruined if these schemes are not founded on sound lines, and have put their own fortunes to the stake. I am as absolutely sure of the soundness as they are themselves.

Oranges and lemons give about the highest ultimate profits, but cost most to put in and take five years to good bearing, as against four years for vineyards and most other fruits. * * * *

Oranges will cost £110 more to plant, and require another year's outlay before good returns come in; 10 acres of oranges and lemons in bearing may thus be estimated to cost £610. For this outlay you can

recon on a minimum net return of £150 per annum from grapes, and certainly £200 per annum from oranges and lemons, even if you use hired labour for the whole of the work, which no man should do. A man who took over the orchard into his own hands after the first year could save most of the expenditure afterwards, and get a higher return by selling cuttings, growing a little lucerne, &c. Thus a father who lays out £1,000 on 20 acres for his son puts the young man into an assured £300 a year, with light out-door work in a pleasant climate, and the most favourable social surroundings. A man who lays out £2,000 on 40 acres for his declining years, and spends £1,000 in a house, has a valuable estate bringing in well over £600 a year to leave his children, has interesting out-door work, and a most social life. If he has daughters they will not stay with him long, but need not go far, as the country will be thickly settled with thriving young men who seek for wives, as young men will do.

The social life is a peculiarity of these settlements; nearly all the men have money, some have a good deal, an extraordinary high proportion are men of birth and education. At Mildura Lord Ranfurly has put in about 200 acres for himself and sons, and there are several retired Melbourne merchants and numbers of young college men settled down already. Renmark is behindhand in extent, but Lord Deramora has taken up a large piece, and several retired military men are at work already too. A steady stream of settlers, well-to-do and mostly gentlemen, has set in from England. There is rabbit and duck shooting to any extent; the great cost of fencing is due to the number of rabbits about, as they have to be kept by strips of 1½ inch galvanised iron wire netting. There is fishing in the Murray (a noble river here, over 1,000 feet wide) mostly bait I fear. I saw several great Murray cod pulled out, 3 to 12 lb., and excellent eating. I saw a lot of smaller fish rising in a back water one golden evening, and there may be a lot to be done with fly and spoon.

It is to be noted that a great number of successful and enterprising colonial fruit and wine growers have started places for themselves or their sons. Taken all in all I have seen nothing like it, nor heard of anything equal to it, either for one's own old age or for a man's sons and daughters. There is one kind of man who must *not* come here, that is the man who cannot get on without first-rate domestic servants; such things are not to be had; the people are too rich, any decent looking girl with homewifely qualities will marry about as soon as she likes, and marry into a comfortable house of her own. A man's great standby must be his wife and daughters (till marriageable) if he has no womenfolk he make an arrangement (or marries) for his meals, and wants no servant in the house. Domestic life is simple and rural. For young men there is constant foot-ball, cricket, bicycling and all manner of out-door amusements; for all there are libraries, reading rooms and plenty of society. Every man is busy all day, and busy with a pleasant sense of being uncommonly well paid for it. The current wages in ordinary work are 6s. 6d. to 9s. per day.

Figures regarding Mildura.—The agreement with the Victorian Government was signed on 21st October 1886, and Messrs. Chaffey began real work on the place in August 1887, having by then got out machinery and put up temporary sheds of sorts. Up to end of June 1891 the company had altogether expended £198,000 on permanent improvements, and their average pay sheets are £7,000 per month for wages alone. One of their pumping engines is a triple-expansion four-cylindered engine of 1,000 indicated horse power, directly driving four centrifugal pumps of 6 feet diameters, with 20-inch inlet and outlet pipes, and from which four such other pumps are to be driven by belts when required, the whole plant being capable of throwing 120,000 to 140,000 gallons per minute when required. There are four traction engines for scarifying, three for grubbing up trees. The Agricultural College foundations are laid, and the building will cost £5,000. The Mechanics' Institute under erection will cost £3,000. There are 300 miles of channels made, 120 miles are from 8 to 25 feet wide and the remainder small distributaries. Cementing the beds

and sides is in hand. The permanent building for a canning factory about to start will cost £2,500. In August 1887 there was but one old squatter's house and a few huts, also 15 tents occupied by intending settlers. There are now over 500 houses and 3,150 inhabitants. The Shire Council, constituted in January 1890, gives the rateable property at £40,000. The customs revenue last year (goods imported in bond) was £3,512. Shipping entered and cleared (river steamers and flats) for last year was 113 vessels of 13,192 tons, employing 798 men. There are a post and telegraph office, customs house, state school (cost £3,000 and enlargements shortly to be made), bank, savings, banks, six general stores, numbers of special stores as saddlers, milliners, &c., a coffee palace (cost £4,000,) a foundry, workshops, and steam printing press. One paper, the *Mildura Cultivator*, got up in excellent style is published there. There is no public-house in the settlement, and the law is framed, both here and at Renmark, to prevent the retail sale of liquor. The effect of this is extraordinary, and furnishes an object lesson which will have wide effect in time. The firm has sold all the town lots, all the villa sites, and about 20,000 acres of fruit land: most of it is sold on a system of instalments spread over ten years and involving heavy interest charges. The areas actually planted by the middle of June were—588 acres oranges, 225 lemons, 368½ apricots, 30 peach, 55 olive, 75 fig, 45 prune, 750 raisin vines, 68 wine grapes, 76½ zante currants, 78 various and nurseries, total 2,359 acres. Planting has been in full swing ever since and will go on to middle of September. At least 3,000 acres must be put in this season, and the Company has ordered 1½ million cuttings from a single firm in Adelaide alone. Several tons of raisins were turned out this year. The characteristics of Renmark are the same as those of Mildura except that the place is newer and the land is not so high above the river, the irrigation will therefore cost less and blocks near the river are still available for purchase. Of the parts that I saw there was a larger proportion of the very best land in Renmark than at Mildura: and taking it all in all I agree with the more recent arrivals from England, who are mostly selecting land at Renmark. Compare the life of a young man started in one of these, with the man who has made an average start in any profession. Compare the cost of starting a young man here with the cost of bringing him up for one of the professions; and compare the average results of the two starts in life! I do not expect all this to have much weight on my single report and advise further reference to the following papers:—

1.—The Australian Irrigation Colonies: a pamphlet containing reprints from official reports of the Victorian Water Supply Department, and from Australian newspaper reports.

2.—The July number of the *Adelaide Garden and Field* containing the South Australian Agricultural Bureau's report on their recent visit to Mildura and Renmark. The members of this Bureau are all practical men, engaged in growing fruit, wine-making, farming, cheesemaking, &c., or business in connection therewith.

3.—Specimen number, July 1891, of the *Mildura Cultivator*, printed and published at Mildura.

4.—Memorandum of terms and conditions of sale of the Renmark irrigation lands, issued by the Chaffey Irrigation Colonies Co., Ltd.

I commend these to the most careful attention of Anglo-Indians who are looking out for the same sort of opening that I have been. They contain full information. If several of us were to take contiguous blocks we could save the division fences, or about £14 on every 10 acres. By working together those who are present at any time can look after the interests of the absent, and, as the custom of business is, the combined interests representing a large area will get more consideration than the separate units would and can always obtain sundry convenient concessions. With this view I went very carefully over the land around Renmark, and selected a piece of rich, open, sandy-loam of a strong red colour within three miles of the township, and about two furlongs from the main avenue, which will be the first to have a tram line on it. The soil is in every respect better

sited for irrigation than almost any I have seen during over twenty years' experience on Indian canals. There is a small ridge just suited for building on above the irrigated land. The land is lightly timbered with Murray pines and other easily uprooted scrub: it will not cost much to clear. The pine is not attacked by termites or borers, and is therefore valuable for fencing and house building.

Messrs. Chaffey are alive to the probable advantage of getting a number of retired Anglo-Indians with fairly good means to settle on the land, and have courteously marked out a block of 20 acres of this land which they will reserve for applicants through me for one year, *i.e.*, up to the end of July 1892, but on the condition that the purchasers of this reserved land buy for ready money. Adjoining this is the land of Lord Doramore; in, I think, slightly inferior soil. The map of it will reach me a few days hence. There is no fear of losing by the purchase of this land, it will rise in value day by day with the progress of the settlement, just as similarly situated land at Mildura has already done. I wish I had the money to buy and plant the whole of it. The man who puts in a vineyard or orangery at a cost of £45 to £62 per acre, and then does not care to keep it, can easily sell out at a considerable advance whenever he wishes, for settlers—men with money and meaning to buy, are arriving in numbers, six and eight a day sometimes, and money is circulating rapidly. A mere money profit is a certainty, but the splendid open for permanent settlement is what I am looking to. I will be glad to hear from any persons willing to join with me on this reserved 200 acres. Those who wish for independent inquiries can write to the Chaffey Irrigation Company, Limited, King William Street, Adelaide, for all particulars.

The colonies can be seen in ten days from Adelaide, or a very interesting tour can be mapped out to take in Adelaide, the river Murray by steamer from Morgan to Mildura, doing Renmark *en route*, then up the Darling by steamer to take Merrindi, and across by coach to the great silver mines and rising town of Broken Hill, and then back to Adelaide by railway: about £30 will cover the whole trip, with a large margin for extras.

MUSAS.

This handsome group includes several species and varieties of value for conservatory decoration where space is ample, and during the summer some of them are also useful for out-door tropical effects, for which their bold leaves make them particularly desirable. When planted outside, however, the Bananas should have a somewhat sheltered position, for when exposed to the full force of the wind the leaves are often split and torn. These plants are gross feeders and enjoy rich soil, and respond to liberal treatment generally. Another point in their favour is, that they are but little subject to insect pests, unless surrounded by infected plants of other species.

The true Banana, *Musa sapientum*, is rather too large a plant to be included in a small collection, but the variegated form of this species, *M. sapientum vitata*, is an extremely handsome one, and is not quite so rampant in growth as the type. This variety is perhaps the most striking member of the genus, the leaves being oblong in form and the ground color bright green, on which are many stripes and blotches of white. The fruit is of little value, but when planted out in a warm house, and at the same time encouraged in growth by a moist atmosphere and plentiful watering at the root, it makes a very effective specimen. The propagation of this form is accomplished by means of suckers, which, in common with most of the members of this genus, it produces in moderate number.

The Chinese Banana, *M. Cavendishii*, is quite dwarf in habit, and has been frequently fruited under glass, for when full-grown it seldom reaches more than eight feet in height, and has often been fruited when about six feet. Its leaves are from three

to four feet long and one to two in width, forming a rather compact head of dark green color, and the stem is quite stout in proportion to its length. *M. Cavendishii* is also propagated by means of suckers, the latter being thrown up at the time of fruiting, and frequently before this occurs.

M. coccinea is another highly ornamental species, and was introduced from Cochin China many years ago. This species is of comparatively slender growth, and has bright green leaves about three feet long and six inches wide, the entire height of the plant being from four to six feet. The most striking feature of *M. coccinea* is the flower-cluster, which is terminal and about one foot long, and covered with spathe of bright scarlet, making it the most showy member of the genus in this respect. It may be well grown as a pot plant if it be not convenient to plant it out, by giving it a little extra stimulation in the form of liquid manure from time to time.

The Abyssinian Banana, *M. Ensete*, is now well known as a plant for decorative use, either in-doors or out, and is grown from seeds in quite large quantities in some commercial establishments. This is probably the largest species of this genus, the stem sometimes reaching a height of twenty feet, while the leaves are truly immense. The latter are bright green in color, with a red midrib and stem, and stand out boldly in a semi-erect manner. The fruit of this species is of no value except to furnish seeds, these forming the only means of propagation, as *M. Ensete* does not produce suckers. *M. superba* is also a strong-growing species, and bears some resemblance to the preceding, though possibly more compact in habit, and is a native of India. The two last-mentioned are the best species to use out-of-doors, their leaves being tougher than those of most of the others, though *M. Cavendishii* may also be used in this manner if it has not been grown in a close, warm house just previous to removal outside. *M. zehrina*, also from India, is another handsome foliaged species, the leaves of which are oblong in shape, and dark green in color, irregularly blotched with bronzy red and purple. The stem of *M. zehrina* is slender, and the plant seldom exceeds ten feet in height. Its peculiar coloring makes it an admirable contrast when grown in company with *M. Sapientum vittata*.

There are some eighteen species in all, but those specially referred to are the most useful for decorative purposes, and are all worthy of more extended cultivation.

W. H. TAPLIN.

COPPER SULPHATE AS A FUNGICIDE.—"The various compounds of copper offer efficient protection to many cultivated crops against the exceedingly destructive ravages of fungous parasites. Without treatment these rots, rusts, mildews, and blights, frequently destroy a large proportion of, or even the entire products of field and fruit plantations. The applications, in the shape of watery sprays, are made so readily, and with so little expense in money and labour, that everyone interested should at once undertake the work. The practical results already attained, constitute the greatest advance made in recent times in the application of science to horticulture. A little well-directed effort may be confidently expected to return a hundred, or a thousand times its cost. Still there is need for much vigilance and careful attention to every detail. Mistakes may be made even then, and sometimes failures may occur, for which existing knowledge may offer no explanation. But we should persevere, gain all possible information upon the subject, and watch well the effects in every test. In this way, every one may hope to conquer, practically, these insidious and, heretofore, invincible, foes." Such are the conclusions, after numerous experiments, made by Dr. Burrill of the Illinois Agricultural Station, and they are in conformity with general experience in America and in France. When will our people wake up?—*Gardener's Chronicle*.

BERMUDA IN MAY.

To the Editor of *Garden and Forest*.

Sir,—It is not surprising that the genial climate of Bermuda should attract so many winter visitors from our northern states. A sea-voyage of less than three days, and one which a fast steamer might easily make within forty-eight hours, suffices to bring them to shores that are green the year through, and yet an air so equable that the fervors of the summer sun are rarely oppressive or enervating, because the heat is so constantly tempered by breezes from the sea. The change in the political and social atmosphere is quite as striking, for the American citizen will suddenly find himself in a loyal English colony where even the negroes—perhaps the most active and intelligent specimens of their race to be found in all the world—speak with a perfect English accent where fleet or fortress is forever in sight to manifest the imperial power of Britain, and where a large proportion of the men one meets on the street wear the uniform of her army or navy.

The great mass of those who flee to Bermuda to escape the rigors of winter return in April, so that the impressions one receives from a flying visit in late May may be worth recording. The islands are not at their best until June, it is said, and, perhaps, the time is not far away when this will be a favorite haunt for the summer tourist from New York, who could hardly find elsewhere a week or a fortnight of rest and change so perfect and so convenient as that furnished by a trip over cool seas to these breezy islands.

One need not expect any touch of the sublime in the landscapes here, for it would not be possible to crowd many natural objects which inspire awe by their vastness or sublimity within a long and narrow chain of islands containing altogether an area of some twenty square miles. But the land, what there is of it, is pleasantly diversified in surface, rising at one point to an altitude of some 200 feet; and the ever-present sea of itself suffices to insure every wide prospect against the charge of being tame or commonplace. One charm of the sea, by the way, is its marvellous and indescribable color, for the water over these coral reefs outtrivals the azure of the sky in the richness and depth of its blue. There are occasional inland views where, in happy valleys, the sea is shut out of sight by encircling hills, and here, at times, one is reminded of New England, with roads winding along Pine-woods with an undergrowth of Ferns. No Pines are here, it is true, but the Bermuda Cedar, at a little distance, constantly suggests the Pine, and on a nearer view it shows so close a relation to our common Red Cedar that there is nothing strange or unfamiliar in its presence, although the species is confined mainly to these islands. When Juan Bermudez, nearly 400 years ago, was feeling his way along the treacherous reefs which surround them, he saw the islands covered with forests of these trees, which then attained to stately proportions. These forests have been cut and re-cut since, and yet they form the most conspicuous growth upon the island to-day; indeed, the larger proportion of the surface seems forest-clad, for wherever the land is left to itself the Cedar "comes in." It would be naturally supposed from the shiploads of onions and potatoes that reach our markets from Bermuda in the spring that every rod of the scanty territory was under plow or spade, but the visitor's first surprise, and one from which he can hardly recover during a brief sojourn, is, that he rarely finds these articles of export growing in large fields—indeed, an acre would pass for a considerable plantation here—but generally in little pockets a rod or so across, where the red soil is deep enough to furnish root-room for the plants, while all about them the rock is thinly covered or thrusts its massive shoulders quite above the ground.

Next to the forests, clothing the hills which slope toward the shore, one who for the first time sails in sight of them through the tortuous channel which leads to Hamilton is struck with the white houses which nestle in their foliage. These are all built of

the light friable limestone of the island, which is so soft that it can be readily sawed into blocks. Even the roofs are made of thin stone plates, and the whole building is whitewashed till it glitters. In spite of this shining color the houses have no staring or obtrusive effect, but being substantial and low they only serve to deepen the color of green about them, making the landscape more cheerful and investing it with a more home-like and human interest.

Once on the land, the roads are among the first objects to invite attention. Very few level acres can be found on the islands, but these old highways adjust themselves most graciously to the contour of the hills and the curving of the shores, winding in and out apparently without purpose or direction. But in so small an area there is little need of railway directness, and one is glad to lose a little time in travel where there is so much of it in a day. At every turn there is a changing prospect, a new arrangement of sea and shore, of cliff and dell, of Lily-fields and Oleander-hedges. Broken pieces of the soft stone spread upon the road-bed at once pack into a smooth surface over which a wheel delights to roll, and its gray tone blends most happily with the prevailing colors of the landscape. And then the fences, which generally are objects whose ugliness needs some excuse, are here a positive ornament. They are walls constructed of the same sawed-stone blocks and cement which are used in all the island architecture, and they would stand for a century here, where there is no forest to heave them, unless they should chance to be crowded over by the roots of some pushing tree. They seem to have been built along the roads generations ago when slave-labor was abundant, standing everywhere square and firm—now as parapets along the brow of some cliff whose base is beaten by the sea, and again as retaining walls against the face of some cutting—usually bare, gray and honey-combed with age, but often draped and garlanded with Mandrill and other vines, or overhung by huge masses of Cactus. They are always picturesque, and like all solid, heavy and weather-beaten structures, are agreeably suggestive of antiquity. These, then, are the leading features of the landscape which are permanent: a narrow stretch of land, with a rolling and often a rugged surface; bold shores unrounded by a sea of an unspeakable blue; open fields with scant, coarse grass, which leaves them rather brown than green; forests of Cedar with blue-gray foliage; snow-white cottages and a web of roads in a close net-work, uniting with each other at every conceivable curve and angle. Over all hangs a translucent atmosphere which dims the distance, mellows the outline of objects nearer by, and softens away the glare of every intense color. Very beautiful and impressive are the shifting combinations of these simple elements under such a sky.

The efforts of the Bermudians in the past to improve the scenery by planting do not seem to have been as successful as one could wish. So many treasures for gardens in such a climate could be found by searching that one marvels at the scanty catalogue of materials used in the most elaborate places, and yet the gardens are by no means devoid of interest or beauty. Just now the most conspicuous of plants is the Oleander, which grows and spreads with such persistence that many of the islanders count it a nuisance. To a stranger, however, there are few more attractive objects than the great mass which ultimately forms from a single parent stem in rich soil. These are often twenty feet high, with branches arching to the ground in a circle whose diameter more than equals the height—green mounds starred all over with bright flowers which range from pure white through shades of pink to almost crimson in some cases. All that is needed to start an Oleander-hedge is to place a row of cuttings in the ground, and one often sees a broad belt of these plants extending entirely around the boundary of some estate. The Chinese Hibiscus is, perhaps, next to the Oleander in abundance, and it seems equally luxuriant. In many places these plants are sheared into formal hedges, and the great flowers open on the smooth face of this verdurous walls as freely as

on the plants which are left to develop into fair-sized trees. *Tecoma Capensis* is another plant which is largely used in hedges, and, just now, it is brilliant with orange-colored flowers, while *T. stans*, one of the most beautiful of yellow flowering shrubs or small trees, is at the height of its bloom. The Tamarisk, here as elsewhere, shows its sturdiness against the salt-laden gales of the sea-coast, and has been planted very largely and with good judgment in exposed places on the shore. The gorgeous blooms of *Poinciana regia* had not yet appeared, but its relative, *P. pulcherrima*, was growing and blooming everywhere. Occasionally fine masses of Bamboo are seen, and these, with the native Palmetto (*Sabal Blackburniana*), the ever-present Banana, and some of the hardier Palms, are the most distinctly tropical features of the scenery, although the Poinsettias, Pomegranates, Bignonias (especially *B. pentaphylla*, known here as the White Cedar) the so-called Sand-plant, *Erythrina speciosa*, with brilliant scarlet flowers on bare branches, and large specimens of the India Rubber-tree wear a strange look to northern eyes. Of course, this is not meant to serve as a complete list of the garden plants of the island, but only to recall those which were sufficiently conspicuous at this season to impress a casual visitor. Space would fail to mention the striking individual plants, like the two fine "Gru-Gru" Palms (*Azorecaryum aurum*) at Mount Langton, but Roses ought not to be omitted, for, although our hardier kinds do not flourish here, those with some blood of the Teas or other tender strains, like Lamarque, for example, were bearing fine flowers in profusion. In the Governor's grounds a superb specimen of *Rosa bracteata* showed that the soil and climate were well adapted to this beautiful species.

How readily some plants will become naturalized when they find favorable conditions is shown by the case of one of the Jessaminos (*J. gracile*) which was brought to the islands in 1840. It soon escaped from cultivation, and now it is clambering over the rocks and making an almost impenetrable tangle in the woods of a broken region near the famous Walsingham tract. It is a delightful vine with glossy and fragrant white flowers, and it seems strange that more general use has not been made of it. It would make a charming addition to the landscape if allowed to clamber over the walls along the highways. Occasionally one sees a European Elder, which grows here with great vigor, and is always a beautiful tree. The islanders seem to have caught the European habit of setting it close to the sides of their houses, and it shows to great advantage against their walls. This masking of the house-foundations with shrubbery, however, is no more generally practiced than it is in the United States, but these stone houses would seem to offer excellent opportunities for making such connections with the earth. By one cottage along the road which winds about the north shore stands a pair of Agaves close to the front wall, one on either side of the entrance of a narrow loggia, and the sharp stiff leaves against the white stone produce an effect that no one who drives by them will forget.

All the world knows how extensively the bulbs of the great Easter Lily are cultivated here, and the more beautiful old Ascension Lily, *L. candidum*, flourishes equally well, while Hippeastrums (Amaryllis) and Freesias grow like weeds. At many seasons the fields are brighter than the gardens, but Bermuda is a land of flowers at all times. Our northern states in late May are so attractive that one hesitates about leaving them even for a short absence. But when a few hours can land us amid the vegetation of the tropics, under a new sky and encircled by a strange sea, the change will prove a pleasing one, and the return will bring a keener appreciation of the rare loveliness of our northern spring.

New York.

S.

CARBONATE OF COPPER may be made by dissolving 1 lb. of copper sulphate in 2 gallons of water, and 1½ lb. of soda carbonate in half a gallon of water; mix the two solutions; a brownish powder will be precipitated; the water should be poured off from the precipitate, which is the copper carbonate.—*Gardeners' Chronicle*.

RECENT PUBLICATIONS.

Description et Emploi des Eucalyptus Introduits en Europe Principalement en France et en Algérie. Second Memoire. Charles Naudin. Antibes, 1891, pp. 1-72.

The first memoir published by Monsieur Naudin upon the Eucalyptus cultivated in Europe appeared in 1888. Since that time the veteran French botanist has continued his investigations, and has been able to study a much larger number of species in the garden of the Villa Thuret, over which he presides, and in which he has brought together the largest collection of these trees which has been formed; and in the present paper he arranges fifty-six of them in synoptical tables according to the shape of the leaves, the flowers and the fruit, so that the cultivator of these trees will be able now much more readily than ever before to determine the different species, which have always proved extremely difficult to understand from the fact that many of them appear entirely different in their juvenile and adult states, producing at first leaves of one sort and then later in life leaves of an entirely different shape and character. To overcome this difficulty in the study of the genus Monsieur Naudin has made a special Eucalyptus herbarium, in which are represented all the species cultivated in Europe, by specimens taken at different periods of their growth, and showing all the different stages through which they pass from youth to maturity. In these studies it may be mentioned that Monsieur Naudin has brought to light among the plants cultivated at Antibes no less than thirteen undescribed species, now first made known in this memoir, a fact which shows the value of arborata and the importance of studying trees in a living state, where different species can be compared with each other and their differences noted.

A few brief extracts from the general considerations which form the first part of this work will be interesting, perhaps, to our readers, especially as different species of Eucalyptus are destined to play, it seems, an important part in the future of California, where many of them have long been successfully grown. "The most interesting things," Monsieur Naudin remarks, "about the genus from the cultural point of view, is the rapidity with which certain species grow, a rapidity which is unequalled by any of our native trees, and the quantity of wood valuable for manufacturing purposes and for fuel which they can produce in a comparatively short time. To this advantage possessed by these trees must be added that of being able to support themselves much farther south than most of our forest-trees of Europe, even to the southern limits of the Algerian Sahara, although the region in which they can be cultivated is extremely restricted on the north. There are certain species, however, natives of Tasmania and of the high mountains of southern Australia, which will succeed beyond the Mediterranean region, and which can be cultivated on the Atlantic coast as far north as Brittany, and even in the south-west of England. In countries with warm and humid climates, especially in equatorial regions at the sea-level, the introduction of the Eucalyptus has so far been a failure. There is reason to believe, however, that there are certain species of the intertropical regions of Australia and of the Malaysian Islands which might be expected to succeed even in the tropics. More than a hundred species are now known, and it is easy to understand that from this number there is a considerable choice to be made, according to the usages for which they are intended. Most of the species are forest-trees, some reaching in a comparatively short time a colossal size. Their principal value, then, is the production of timber, although the value of their wood for fuel is almost as great—a quality which will be appreciated in countries where the absence or high cost of coal is a serious obstacle to the production of metals or to the use of steam-engines.

"Two species may be distinguished among all the others for the rapidity with which they reach a large size; these are *E. globulus* and *E. Mulleri*; and they grow much more rapidly than any of the native trees of Europe. In twenty years these trees attain to the size and height of an Oak a hundred years old. Other species, without growing as rapidly, are still remark-

able for the short time they require in which to grow to a size large enough to produce valuable material. Such species are *E. diversicolor*, *E. marginata*, *E. crebra*, *E. botryoides*, *E. robusta*, *E. leucocylon*, *E. Gumii*, *E. riminalis*, *E. rudis*, *E. cosmocalix*, *E. rostrata*, *E. gomphocephala*, *E. cornuta*, *E. amplifolia*, *E. tereticornis*, and *E. polyanthema*. The wood of some of these species is exceedingly heavy, and might be used to advantage for blocks for paving the streets of cities."

"The climate is not all that is necessary to insure the successful cultivation of Eucalyptus. The character of the soil is important. Many species, it is true, are not particular in this respect; others, on the contrary, are apparently very fastidious, and if the soil is not suitable to them they grow badly or soon die outright, either immediately after the seed has germinated or in the course of a year or two afterward. It is difficult to say with our present knowledge what they need, although experience seems to show that granite or sandstone soils suit them, as may be seen on the shores of Provence, where such soils are the most common. It is also necessary that the soil in which they are planted should be well cultivated and freed of other aborescent vegetation. The Eucalyptus cannot bear the neighbourhood of other trees, dispting the possession of the ground and depriving them of the light of the sun. When it is attempted to grow them in the shade, they become drawn up and give unsatisfactory results. No Eucalyptus can grow on land impregnated with salt, and they all suffer when planted so near the sea that salt spray reaches their leaves. Bright light and a free circulation of air is indispensable to these trees, two conditions made necessary by the large amount of water evaporated from their leaves, for it is well known that the Eucalypti exhale a large quantity of water drawn from the soil drained by their roots. Certain species, particularly those which grow naturally in the most arid regions subject to long droughts, store water in their roots and in the lower part of their trunks, which are sometimes enlarged into a sort of hulk, and from which they draw the water necessary for their existence during periods of excessive drought. It is useless to hope that arid rocky hills can be covered with forests of large Eucalyptus, which require for their rapid growth an abundance of soil."

"The seeds of Eucalyptus may be planted at different periods of the year, according to regions and climates. With us the best time is the spring—in March, April or May—for if the seed is sown at that time, the young plant will have sufficient strength to support the cold of the following winter. In forming a plantation of Eucalyptus, it is of prime necessity to decide upon the object to be attained, that the species may be selected best suited to accomplish it. If, for example, it is desired to obtain timber in as short a time as possible, *E. globulus*, *E. Mulleri* or *E. gomphocephala* should be planted. If very heavy wood is desired, then *E. marginata*, *E. rostrata* and especially *E. polyanthema* should be used. If it is a question only of obtaining handsome trees for the decoration of parks or avenues, one would choose naturally the species most remarkable for the beauty of their growth, for the dense shade cast by leaves and by their abundant flowers, such as *E. robusta*, *E. cornuta*, *E. botryoides* or *E. leucocylon*."

These short extracts will give, perhaps, an idea of the scope and character of Monsieur Naudin's contribution to dendrological science. For the full account of the Eucalyptus, as known in Europe, however, we must refer our readers to the paper itself, which, it seems to us, might with great advantage be reprinted in this country for the benefit of the rapidly increasing class of people whose homes are in southern California, where the cultivation of these trees is every year becoming a more important industry. —Garden and Forest.

THE INDIA-RUBBER TREE.

To the Editor of *Garden and Forest*.

Sir,—Referring to the article upon the India-rubber tree published in your issue of November 13th,

it is, perhaps, worth while to call attention to the ease with which that beautiful tree can be propagated for cuttings. As is well known, it is only necessary to take a piece of a branch and insert it into moist sand and to protect the cutting with a bell-glass to secure a rooted plant; but it is less well known, perhaps, that the last articulation of the branch is capable of making roots much more quickly and readily than those lower down. Mr. Gamble, inspector of the forests of Madras, in South India, tells me that when they desire, in his district, to make plantations of this valuable tree, workmen always take the end of a branch with a single leaf for the cutting, as experience has shown that this is the way to obtain plants quickly and surely, and I believe that horticulturists would do well to follow this plan always in propagating *Ficus elastica*.

This tree, by the way, does not demand a real tropical climate. On the contrary, it flourishes outside the tropics in regions where snow falls sometimes and which experience several degrees of frost. I have seen in the beautiful garden of Hamah, near Algiers, specimens of *Ficus elastica*, and of its relative, *F. Roxburghii*, as large as our large forest-trees, casting a shade blacker and thicker than I have ever seen before. Generally, the genus *Ficus* is hardy and easy to acclimatize.

Ficus australis succeeds admirably in Algiers, and *F. Benjaminia* is used in the same city as a shade tree in the suburb of Mustapha. There is a large specimen of *Ficus australis*, already old, on the Italian Riviera at Mentone, which, protected on the north by a house, forms a superb mass of dark green foliage; and at Cadiz there is a handsome avenue of large Fig-trees, with small leaves, not far from the Botanic Garden. These are trees two feet or more in diameter of trunk, with thick spreading heads. There are often severe frosts, however, in all those regions.

With regard to the fruit of *Ficus elastica*, I have once seen it on a small plant cultivated in a pot at Bale, so that it appears that this species bears fruit sometimes in a comparatively young state.

Bale, Switzerland.

H. CRIST.

—Garden and Forest.

PLANTS OR TREES PER ACRE.

The following table will be found very convenient, as giving the number of plants or trees on an acre:—

6 in. each way, 151,240	6 ft. each way, 1,200
1 ft. " " 43,500	8 ft. " " 699
1½ ft. " " 19,306	10 ft. " " 430
2 ft. by 1 ft. " 21,780	12 ft. " " 300
3 ft. each way, 10,890	15 ft. " " 200
3 ft. by 2 ft. 7,260	18 ft. " " 135
5 ft. each way, 4,840	20 ft. " " 110
4 ft. " " 2,730	22 ft. " " 90
5 ft. " " 1,750	30 ft. " " 50

Rows 6 ft. apart, and trees 1 ft. apart in the row, 7,315 trees per acre.

Rows 8 ft. apart, and 1 ft. apart in the row, 5,431 trees per acre.

Rows 10 ft. apart, and 1 ft. apart in the row, 4,389 trees per acre.

One mile of wind-breaks or shelter-belts requires 4,280 trees or cuttings for a single row, 1 ft. apart in the row.—*Adelaide Observer*.

BOTANICAL ENTERPRISE IN THE WEST INDIES.—The May number of the *Kew Bulletin* is devoted to a record of the steps that have been taken to organise botanical stations for the introduction, trial, and diffusion of plants of economic importance. This *Bulletin* also contains the text of Mr. Morris' report on his recent visit to the West Indies, embodying the results of his visit to the several islands, and the lectures therein given. His mission occupied 106 days, and the distance covered was a little over 12,000 miles. As we shall have another opportunity of alluding to Mr. Morris' work, and of illustrating a new dwarf Palm discovered by him, we content ourselves for the present with this brief mention.—*Gardeners' Chronicle*

GRASS SEEDS.—Few continental cities can show such beautiful lawns as those of England. The turf at the German exhibition is English, having been sown down with Suttons' Grass seeds. We also learn that the seeds sown to form the velvet carpet of the arena at the Naval Exhibition, which was the only cheerful sight out-of-doors on the opening day, were supplied by the same firm.—*Gardeners' Chronicle*.

SUTTON'S POTATOES IN CEYLON.—We learn that Messrs. Sutton & Sons, of Reading, were awarded a Gold Medal at the Ceylon Agri-Horticultural Exhibition, held at Nuwara Eliya on April 1, 1891, for a collection of Potatoes of excellent quality grown in the gardens of His Excellency the Governor of Ceylon, and included Abundance, Satisfaction, Seedling, Windsor Castle, Masterpiece, &c., all varieties of Messrs. Sutton's raising.—*Ibid*.

STEM-FORM IN CACTI.—A correspondent lately sent us stems of a hybrid between *Phyllocactus crenatus* male and *Cereus speciosissimus* as the female parent, with the remark that the seedlings all produce angular stems at first, but that subsequently they become flattened, as in the male parent. It was not unnaturally supposed that this change of form was the result of a dissociation of hybrid characters (a sport); but, unfortunately for this interpretation, we find that the stems of *Phyllocactus* frequently produce angular branches without any crossing at all.—*Ibid*.

FORESTRY IN IRELAND.—The first special annual return by the Registrar-General of forestry operations in Ireland has just been issued. It appears that 1,498 acres were planted with trees in Ireland during the year ended June 30, 1890, of which 384 acres were in Leinster, 556 in Munster, 329 in Ulster, and 219 in Connaught. The total number of trees planted on the 1,498 acres was 350,230. Larch trees constituted more than one-third, and Fir trees about 12 per cent. of the total number planted. The number of trees felled both for clearance and for thinning plantations, during the year ended June 30, 1890, amounted to 1,256,887. About one-half of the total number felled consisted of Larch trees. The area returned as cleared is 1,399 acres—namely, 400 in Leinster, 786 in Munster, 165 in Ulster, and 48 in Connaught.—*Ibid*.

MILDEW.—Our American cousins find the practical advantage of spraying their trees for mildew and various insects. Mr. B. T. Galloway, of the United States Department of Agriculture, in a circular issued by the Department, says that experiments have proved conclusively that powdery mildew of the Apple, Pear, &c., can readily be controlled at comparatively little expense. Ten millions of young fruit will be treated this year. The Bordeaux mixture, or the ammonia solution (carbonate of copper, 5 oz., to 3 pints of strong liquid ammonia), dissolve, and mix with 45 gallons of water. A suitable spray-pump should be used, such as the knapsack-pump, or a barrel-pump, drawn by a horse. In no case should the treatment be delayed beyond the period when the leaves are half grown. Early treatment, vigilance, and repetition of the spray every twelve days, are the most important points to be kept in mind.—*Ibid*.

CHINA GRASS.—This well-known fibre, the produce of a Nettle-like plant, *Böhmmeria nivea*, has been re-introduced of late with the idea of supplanting silk, cotton, and worsted in the cheaper class of goods to be used in upholstery wherever strength and durability are required. From the samples before us, it is evident that the fibre is capable of being dyed in a good range of colours. In appearance, it is between fine wool and flax-thread, being less glossy than the latter, and scarcely so rough as the former. At present, the cost of producing the fibre is a bar to its utility, but it is hoped that this objection will shortly be removed, and that it will then take a prominent place amongst materials for weaving, as the plant from which it is produced can be readily grown in many of our colonies. The fabric known as grass-cloth is manufactured from the same fibre. It is a pity the name "grass" should be attached to it, as it has as little to do with grass as it has with Cucumbers; but for persistence of error, there is nothing to be done.—*Ibid*.

BLACK TEA AND GREEN.

What is the difference between black tea and green tea? Are they produced by different plants or merely by different methods of treating the leaves? And are the Oolong and Japanese teas, so popular in this country, really green teas or black? One so often hears these questions asked, and so seldom gets a reliable answer, that our readers may be interested in the following account of Japanese tea-production which we quote from Mrs. Seidmore's "Jinrikisha Days in Japan."

The Tea-plant, as every one knows, is a hardy evergreen of the Camellia family. It grows a thick and solidly massed bush, and at first glance at a field regularly dotted and bordered with the round bushes setting close to the ground, one might easily mistake it for Box. In the spring the young leaves crop out at the ends of the shoots and branches, and when the whole top of the bush is covered with pale, golden-green tips, generally in May, the first picking takes place. The second picking belongs to the fire-fly season in June, and after that green festival tea comes in from the plantations in decreasing quantities, until the end of August. The choicest qualities of tea are never exported but consumed at home. Choice basket-fired tea, such as is used in the homes of the rich and well-to-do Japanese, sells for one or two dollars a pound. There are choicer, more carefully grown and prepared teas which cost as high as from seven to ten dollars a pound, but such teas are shaded from the hot suns by matted awnings and the picker, going down lines of these carefully tended bushes, nips off only the youngest leaves or buds at the tip of each shoot. The average tea brought by the exporters for shipment to the United States and Canada, is of the commonest quality and, according to Japanese trade statistics, the average value is eleven cents a pound, as it stands, subject to the export duty and ready for shipment abroad.

Japan tea came into market as a cheaper substitute for the green teas of China, those carefully rolled Young Hysons and Gunpowders of our grandmothers' fancy. Europe has never received the Japan teas with favour, but the bulk of American importations is Japanese. . . . For green tea, the leaves are dried over hot fires almost immediately after picking, leaving the *theine* or active principle of the leaf in full strength. For black tea, the leaves are allowed to wilt and ferment in heaps for from five to fourteen days, or until the leaf turns red and the harmful properties of the *theine* have been partly destroyed. The Oolong tea of south China is nearest to green tea, its fermentation being limited to three or five days only while the richly flavored black teas of north China are allowed to ferment for twice that period, to prepare them for the Russian and English markets. . . . The Japanese government made experiments in the manufacture of black tea in the province of Ise, but the results were not satisfactory, and no further efforts have been made to compete in that line with China. Japan will continue to furnish the world's supply of green tea. . . . The young tea-leaves, picked in May and early June, comprise more than half the whole season's crop, succeeding growths of leaves being coarser and having less flavor. Tea which is to be exported is treated to an extra firing, to dry it thoroughly before the voyage, and, at the same time, it is "polished," or coated with indigo, Prussian blue, gypsum and other things, which give it the gray lustre that no dried tea-leaf ever naturally wore, but that American tea-drinkers insist on having. Before the tea-leaves are put in the pans for the second firing, men whose arms are dyed with indigo to the elbows, go down the lines and dust a little of the powder into each pan. Then the tossing and stirring of the leaves follows, and the dye is worked thoroughly into them. . . . This skilled labor is paid for at rates to make the Knights of Labor groan, the wage-list showing how impossible Tea culture is for the United States until protectionist tea-drinkers are ready to pay ten dollars a pound for the commonest gardens. During the four busy months of the tea-season the fires are

paid the equivalent of eleven and four-tenths cents, United States gold, for a day's work of thirteen hours. Less expert hands, who give the second firing, or polishing, receive nine and six-tenths cents a day. Those who sort and finally pack the tea and who work as rapidly and automatically as machines, get the immense sum of fifteen cents. . . . Each year the United States pays over \$7,000,000 for the nerve-racking green tea of Japan.—*Garden and Forest*.

[Mrs. Seidmore must surely have been sadly misinformed as to length of fermentation and as to harmful qualities in the tea: this is the first we have heard of them.—Ed. T. A.]

WOOD PULP INDUSTRY.

Extract from the Report of the Chief of the Division of Forestry, U. S. A. for 1890, by E. Fownow.

It can be said, without fear of contradiction, that in no field of industrial activity has a more rapid development taken place within the last few years than in that of the use of wood for pulp manufacture. The importance of this comparatively new industry for the present, and still more for the future, can hardly be over-estimated. Its expansion during the next few decades may bring revolutionary changes in our wood consumption, due to the new material, cellulose, fiber or wood pulp.

Though rapid in its growth, the industry has by no means reached its full development. Not only is there room for improvements in the processes at present employed, but there are all the time new applications found for the material. While it was in the first place designed to be used in the manufacture of paper only, by various methods of indurating it, its adaptation has become widespread; pails, water pipes, barrels, kitchen utensils, wash-tubs, bath-tubs, washboards, doors, caskets, carriage bodies, floor coverings, furniture and building ornaments, and various other materials are made of it, and while the use of timber has been superseded in shipbuilding, the latest torpedo ram of the Australian navy received a protective armor of cellulose, and our own new vessels are to be similarly provided. While this armor is to render the effect of shot's less disastrous by stopping up leaks, on the other hand bullets for rifle use are made from paper pulp. Of food products, sugar (glucose) and alcohol can be derived from it, and materials resembling leather, cloth, and silk have been successfully manufactured from it. An entire hotel has been lately built in Hamburg, Germany, of material of which pulp forms the basis, and it also forms the basis of a superior lime mortar, fire and water proof, for covering and finishing walls.

Ten years ago there were in Europe about five hundred woodpulp establishments, making in round figures 15,000 tons of ground pulp, valued at over \$5,000,000. With the development of the chemical processes since then, it is hardly possible to tell from day to day how fast the production increases.—*Indian Forester*.

TRANSACTIONS in jute fell off to a remarkable extent in Tippera last year. The Commissioner of the Chittagong Division writes that the price of jute in Tippera fell from Rs. 8 to Rs. 8 per maund, and that, in consequence, the cultivators were reported in some places to have left the jute uncut. No actual distress was felt, though the extraordinary fall is said to have largely affected the revenue administration of the district.—*Calcutta Englishman*.

INSECTICIDES, ETC.—Our growers, whose general apathy with regard to the employment of remedies, even for experimental purposes, is profound, and who appear to leave unread the evidence that is put before them, are, at any rate, not the only persons similarly affected. This is what is said by the *Colonial Botanist* at the Cape:—"I have urged several importers to speculate in a sample, and done everything except thump them over it. But they, one and all, seem to think the Cape fruit grower will not bother over his fruit trees, or put other money or elbow-grease into the protective measures which the Yankee fruitist finds to pay hand over hand. Let us hope they are mistaken."—*Gardeners' Chronicle*.

WORLD'S FAIR NOTES.

THE GREAT INDUSTRIAL MINERALS AND METALS WILL CONSTITUTE AN IMPORTANT FEATURE OF THE MINES AND MINING EXHIBIT AT THE EXPOSITION.

In no other department of the World's Columbian Exposition, perhaps, will be seen a greater diversity of exhibits than in that of Mines and Mining. Not only will there be a dazzling array of diamonds, opals, emeralds and other gems, and of the precious metals, but a most extensive collection of iron, copper, lead and other ores, and of their products; of coal, granite, marble, sandstone and other building stone; of soils, salt, petroleum, and, indeed, of almost everything, useful or beautiful, belonging to the mineral kingdom. How extensive the mineral exhibits from other countries will be, it is yet too early to know, but the indications are that it will surpass any that has heretofore been made. However that may be, there is no doubt that the mineral resources and products, not only of this country as a whole, but of each state and section, will be of the most complete and representative description.

The coal industry in the United States is of gigantic proportions, involving the investment of many millions of capital and the subsistence of many hundreds of thousands of people. According to recent census bulletins the output of coal in 1880 alone aggregated 104,576,299 tons, the value of which at the mines was \$131,431,172. Fully two-thirds of the states and territories are coal producing. But great as is the annual production of coal in this country it is insignificant in comparison with the possibilities. Our coal resources are simply enormous. Vast areas of coal measure, thousands of miles in extent, lie distributed between the Atlantic and Pacific and the northern and southern boundaries. Throughout the west and south coal mining is rapidly increasing in importance.

The exhibit of coal at the Exposition, of course, will be qualitative rather than quantitative. Not only will the different varieties of coal, which the different localities produce, be shown, but chemical analyses of each and the results of tests determining economic value and adaptability to various uses. The coal resources of the different states and sections will be shown by geological maps and drawings showing configuration, stratification, etc., which will render apparent the extent and accessibility of the coal beds and veins. For example, it will be shown that coal measures of varying thickness underlie a great portion of the state of Texas—some 40 or 50 counties—and that, although the coal production of Texas has thus far been comparatively small, the supply is practically inexhaustible, and that much of the coal is of excellent quality. Chief Skiff is enlisting the co-operation of large coal exchanges and corporations, and expects to have a very extensive and complete exhibit.

So too, as regards iron. The most strenuous efforts will be made to have an exhibit worthy of that great branch of industry. This country is now the first nation in the world in iron production, having recently forged ahead of Great Britain, its only real competitor. Our production of pig iron now exceeds 10,000,000 tons annually, or nearly four times what it was ten years ago, and the production of steel now aggregates about 5,000,000 tons a year, a growth of nearly 300 per cent. in the decade. The development of the iron resources of the Southern states has been especially great and rapid. The display at the Exposition will be prepared and collected under the fullest appreciation of the magnitude and importance of the iron industry. There will be shown all the many varieties of ores, with full data as to the location and extent of their beds, the analysis of each ore, and, so far as possible the different processes of treatment in the manufacture of iron and steel.

NOTES ON PRODUCE AND FINANCE.

TEA COMPANIES AND INVESTORS.—We reproduce Mr. H. Earnshaw's valuable statistical table of Indian tea companies, and we recommend investors to study it. If there are better investments than well selected

tea companies, we have not had the good fortune to meet with them. It is useful, however, to know something about the past and present of the various gardens before making a selection, and if further information than that given in this table is desired it is not difficult to procure, and it is worth taking a little trouble about.

JAPAN TEA.—In his report of the trade of Hioogo and Osaka for the past year Mr. Consul Enako states that, owing to the incessant rains having forced the growth of the leaf, the quality of the first crop proved disappointing, and had it not been for the effect which the marked advance in silver had on exchange (higher rates preventing later tea from being laid down as cheaply), there can be little doubt that the season would have proved an unsatisfactory one to shippers. As supplies increased, prices gradually declined, until they showed a drop of from two to three dollars on the earlier prices paid for the better descriptions of leaf, and one dollar for common to medium grades, the latter being throughout the season most in request. The second crop was more satisfactory in quality than the first, and towards the middle of July some slight concessions on the part of holders, coupled with encouraging advices from the consuming markets, led to considerable business, the lower grades again meeting with most enquiry. Increased firmness on the part of sellers followed, supplies being also withheld with a view to forcing up prices, and as the season progressed a marked deterioration both in the quantity and quality became noticeable. A decline of 50 per cent in Suez freights materially assisted the Japanese in maintaining values, notwithstanding the high rates of exchange then ruling, and business continued on about the same basis until the end of September, holders taking advantage of every opportunity to raise prices until they reached such a point as to render further buying unremunerative, especially in view of the inferior selection and paucity of stocks, which by this time had dwindled down to some 270,000 lb. The financial crisis in Europe, in the fall of the year, put a sudden stop to business in the United States of America, the effects of which was quickly felt on this side, and the season was virtually closed by the end of October, although, as usual, a few desultory purchases continued to be made, amounting to some 530,000 lb. The total business for the season was 21,839,431 lb. that for 1889 having been 18,245,735 lb.

LAST WEEK'S TEA MARKET.—The *Gyocar* says:—At last we are beginning to see a little more daylight. The total estimated out-turn from India is now reduced to 108,000,000 lb. Shipments from China have lately been on a very small scale, and instead of being 4,000,000 lb. in excess, is now brought down on a par with last season's, owing to the falling off in the export from Foochow. The news from China is getting more serious, and latest private telegrams say that civil war is imminent. The supply of common tea from China is likely to be very small, and already the terminal market is reflecting the opinion of those who ought to know by a rise of 2 to 3 points; spot has been done at 5 11-16d, and May at 5 3/4d., while Indians are also much stronger. Privately there is no demand, and the public auctions of 17,400 packages showed panic prices. China teas offer most wonderful value, yet dealers say that if they buy them they do not get the retailers to take them, and exporters do not take any quantity. Importers cannot go on taking such ruinous losses, and, we believe, many will hold off their teas for a better market—at present there is none. The public sales of Indian tea have again been on a scale of magnitude, having been even heavier than previously, and unprecedentedly large, reaching 37,320 packages; but a greater portion than preferred consisted of the poorer qualities, which caused the demand to drag somewhat, as if the trade were over-supplied with these, and, although the bulk was disposed of, prices here and there again ruled slightly in favour of the buyer. For the smaller proportion of the finer and more useful grades, however, there was a decidedly firmer tone, and they were taken off with greater readiness at full to slightly higher

rates, especially for strong liquering kinds. The *Produce Markets' Review* says:—The quantities of Indian tea brought forward aggregated upwards of 37,000 packages, including a good assortment of all grades. The market generally showed greater steadiness, and with few exceptions former rates were maintained. The teas from the Assam district were actively competed for, the quality being up to the average of previous seasons, and so long as this is maintained, a good demand may be expected, as prices favour an increasing consumption. There have been no changes of importance in Ceylon teas, but with a continuance of somewhat small sales, prices show considerable firmness. Good flavoury Pekoes at from 9d upwards are in request, and sell freely, whereas, some two months since, such a price as 9 1/2d was almost unobtainable for leaf teas. Broken teas have also been in better demand, and those at from 8 1/2d to 9 1/2d show a rise of from 1/2d to 3/4d from the lowest point. Fine to finest kinds also show a distinct improvement, and the finest lots of the season have lately passed the hammer.—*H. and C. Mail*, Oct. 2.

THE INDIAN COTTON INDUSTRY.

The particulars of last month's exports of cotton from Bombay, which our local correspondent telegraphs today, show a decrease on July as July did on June, but this is probably because the season is drawing to a close. Now that the end of the long lane of depression in the markets of China and Japan appears to have been reached, and a brisk revival of trade in those great markets for Indian goods has commenced the prospects of the Indian cotton industry are more hopeful. The development of the Indian textile industries has been remarkably rapid and yet steady, and there is no reason why, with reasonable caution, this advance should not continue. Six years ago the total textile trade represented a value of about 531 lakhs, and it has now increased to 989 1/2 lakhs, or over 86 per cent. There are 134 mills at work or in course of erection in India, containing 33,51,694 spindles, and 24,531 looms. The average consumption is 4,200,000 cwt of cotton and affords employment to 111,018 hands daily. Thirty-three years ago there were only 12 mills in India, with a spindle power of 338,000, and consuming 227,500 cwt of cotton, Bombay is, of course, far ahead of the other Presidencies and contains on Bombay Island alone 67 mills, with a spindle and loom power of 1,909,123 and 14,374 respectively, and employing 61,981 hands for a consumption of 762,562 bales (of 3 1/2 cwt each) of cotton. In the Presidency of Bombay there are further 24 mills, containing 451,034 spindles and 1,140 looms, and employing 18,140 hands and using 130,158 bales of cotton. The "Kingdom" thus accounts for 94 mills out of the 131 in the Indian Empire. Madras comes next, *longo intervallo*, with 11 mills, containing 243,512 spindles and 555 looms. Bengal has 9 concerns, with a spindle power of 313,000 and 200 looms. The Bengal mills, however, consume 104,858 bales of cotton against 61,614 in Madras.

The mill industry in this country has recently been read a very severe lesson on the evils of excessive production, which has resulted in a combined short time movement in Bombay. Some steps were absolutely necessary, as the China markets, which are the backbone of the Bombay mill industry, had become glutted with supplies so that sales could scarcely be forced even at cost price. There are only two ways of meeting a crisis like this, namely short time or a reduction of wages. The latter course, however, is impracticable in a country like India, where the wages of the operative are a fixed quantity irrespective of the state of trade; so there was nothing else open to the millowners than to agree to short time. This they wisely determined to adopt, and out of the 66 mills at work in Bombay 59 signed an agreement to suspend work for 8 days and 4 days per month (according to whether they were spinning mills only or spinning and weaving concerns as well) from the 15th September to the 31st December,

1891; and the others were expected to sign in a few days. One great difficulty in unanimous stoppage in varied concerns is offered by the different conditions they work under. Some only spin, others spin, weave and dye; others again have a purely local trade, and some mainly an export one. A refusal to co-operate for short time is thus easily understood, unless all the branches of trade are equally depressed. For example, take a mill which spins, weaves and dyes; and one that only spins. The yarn trade being utterly demoralised, it might pay the spinning mill to agree to short time, but not the other, which could get along with its cloth and dyed goods trade. This trouble has been guarded against in Bombay by permitting spinning and weaving concerns to work four days per month more than solely spinning factories, and the Committee of the Millowners' Association is to be congratulated on the success of its scheme, which cannot fail to place the textile trade of Bombay on a much healthier basis. The China market has already recovered from its stagnation, and large transactions are reported to have taken place at advancing rates. With the safeguard of short time against a second surfiting of the consuming centres, the prospects of the Bombay mills are decidedly cheerful. All exporters have again entered the markets, and not only has almost all the ready stock been taken up, but extensive forward contracts, in some cases into the year 1892, have been made. Prices have advanced from a 1-16th to a 1/4 of an anna per pound from the lowest point touched a month ago, and the sales during the first half of the past month have aggregated some 40,000 bales, mostly 10's, 16's, and 20's. The export yarn trade may therefore be said to be in a flourishing condition. A contemplation of the import trade in piece goods and yarns also offers some food for reflection. The figures show that there has been an immense decrease in piece goods, with a slight increase in yarns. The insignificance of Madras trade in piece goods, as compared with the sister Presidencies, is very remarkable. The statistics of exports of piece goods and yarns from India in 1890 and 1891 up to June 30th are eminently satisfactory, pointing as they do to a large increase in both departments.

Having now dealt with manufactured goods, we will turn to the raw material. No reliable statistical data of the imports and exports of cotton are published in Madras and Calcutta, and we can therefore quote no figures of any value. In Bombay the case is different, accurate statements being regularly promulgated. From these we find that the imports of cotton into Bombay this year, (from 1st January to 16th September) from the interior, show a decrease of over 45,000 bales compared with 1890, spread over all varieties except Madras, Westerns, Khandeish, and Bengale. The exports also are very much less than last year. As the exports to China and Calcutta show an increase of 26 and 162 per cent. respectively, the decline is solely attributable to European shipments, and is no doubt due in a great measure to the extensive adulteration and false packing so often alluded to. The season for cotton all over the country was a poor one, and the prospects of the coming crop are infinitely worse. The area under cotton this year shows a considerable decrease as compared with 1890-1, the main cause of which is no doubt the character of the season, and the deficient rainfall, though the diminished European demand, combined with the poor prices obtainable for the Indian staple (due to large American stocks) may contribute to the result. Statisticians calculate that the yield of the coming crop will be 20 per cent below that of last year, and that the quality will be 5 per cent. inferior as to value. Here in Madras the outlook is not cheerful. In Coimbatore, Kurnool, Dharwar, and Bellary the rains have been so deficient and backward that the crop of cotton is likely to fall far short of last season, and as last season's output was about 30 per cent. below the previous year, more than an 8 anna yield can scarcely be counted on. To exporters this is the gloomy prospect, though mill owners can take comfort from the low prices ruling, which will enable them to fill

their requirements at a profitable margin. However taking the cotton trade of India all round, it is in a distinctly flourishing condition, and the enormous strides it has made in the past decade bear evidence to the energy and enterprise of the numerous capitalists who have been engaged upon its development.—*M. Mail*, Oct 3rd.

HAND-WEEDING *VERSUS* CULTIVATION ON TEA ESTATES.

The subject of hand-weeding *versus* cultivation * does not receive the attention which it deserves. The former practice has now for years been observed on many Ceylon Estates, and it would be interesting and instructive to know the comparative results. Planters generally in India, have all along believed implicitly in *cultivation*, and when, now and again, reference has been made in public papers to the advantages of hand-weeding, as practised in Ceylon, it has been lightly passed over, and has perhaps not received the attention which the subject merits. Now that there are so many gardens in the little sister Colony which have come to full bearing, and may well be supposed to have reached their full limit of production in quality as well as quantity, there must be sufficient data to enable us to get at a complete and reliable comparison of results. The most satisfactory comparison must, of course, be in Ceylon itself, if there be a sufficient number of gardens which have persistently carried out a system of thorough cultivation to set against the great number which have practised hand-weeding from the first; failing this we must fall back for the one side upon the experience gained in Assam, Darjeeling, Dooris, etc., and if it can be shown that our friends who labour to the younger Colony gain, as has been often stated, prodigious better results with a smaller expenditure of labour, it is high time that planters in India should "take a leaf out of their book."

There are several points which are patent to all who have had any considerable experience of planting and cultivating tea, and which may be briefly summarized as follows:—

1. A plot which has been kept well dug will invariably yield a much larger quantity of leaf, and better leaf than a plot which has been kept free of weeds by being sickled only.

2. It is exceedingly difficult to make tea grow upon an old road, or a piece of ground which has, for many years, been the site of houses, or otherwise been continually beaten down, and tea grown upon such places will for many years, produce next to nothing.

3. Land which has, by means of cattle passing over it, or otherwise, become trodden down, in course of time becomes (1) less productive of jungle; (2) the *class* of jungle becomes different, and (3) finally as the process goes on jungle disappears altogether. There are some other things such as the following which may have escaped the observation of some planters. Young tea which has been only hand-weeded, and which has had no proper stirring up of the soil from the time of planting till, say, three years old, throws its lateral roots much nearer the surface than tea, which has had a periodical digging *suitable to its age*, it may be the mere breaking of the soil round the plant with the fingers the first year, and digging more or less deeply with an implement afterwards; again on sloping land where the surface soil has been from rush of water, or a bad system of cultivation, carried away from the roots of the plants to a depth of eight inches or more, the lateral roots, of course, become exposed, and on poor soil it usually happens that the plants become sickly, or are killed outright; but it is invariably the case in such instances that if the sub-soil (or the remaining soil) is

* Cultivation in India means a periodical turning down of the weeds into the ground by means of the hoe,—our Ceylon "mamoty."—*Ed. T. I.*

† For "many," "all" might be read. The leading Ceylon planters are opposed to "cultivation" which involves cutting masses of tea rootlets.—*Ed. T. I.*

good and fertile the plants will (with cultivation) continue to flush vigorously, and, in course of time, look as healthy and well as similar plants which have not lost any soil. On most of the old gardens in the Darjeeling district there are plots where such plants are to be seen; the original collar of the plant standing twelve inches or more above the surface of the ground with the stumps of the old lateral roots sticking out, like the knots on the club of "Giant Despair," and, at the same time, the bush itself is in a high state of efficiency, flushing quite as well as any plants in the particular plot; thus showing that the plant has established new lateral roots as required by the altered conditions.

Now it remains to be stated what bearing all these facts have upon the question of hand-weeding *versus* cultivation. With the former treatment, it seems reasonable to expect that before very long the weeding can be done very cheaply, because the soil must become caked and hard from coolies' treading upon it for the purposes of plucking leaf, pruning, etc., but it is reasonable to suppose that the same causes, which result in the killing out of weeds, will also operate towards weakening tea plants and reducing their efficiency. On the other hand, it is a well-established fact that deep cultivation stimulates the growth of the plants, and even if such cultivation is done in such a rough and uncouth way as to cut away many of the lateral roots, the plant does not receive any permanent injury, but soon repairs the damage done. Hand-weeding on old tea has been done on some gardens in Darjeeling district, and with great success but only during a month or two of very wet weather, and only when the soil has previously been dug very deep and thoroughly pulverized.—*Indian Planters' Gazette*.

A REVIEW OF THE PRICES OF QUININE IN THE U. S. MARKET.

The conditions of demand and supply in medicinal articles vary to an extent almost unheard of in many other articles of commerce, and these variations have nowhere been more marked than in quinine. We reprint, on another page, a tabular statement of some interesting facts concerning the range of prices of quinine during a very considerable period. A thoughtful perusal of these tables will serve to bring to the mind of the observer not merely the fluctuations in the price of this valuable commodity, but might furnish a thread on which to hang the history of modern pharmaceutical chemistry.

After passing out of the category of a mere curiosity the alkaloid gradually settled down toward a price which admitted of its general use. Improvement in manipulation and possibly also increased competition sufficed to maintain the general downward tendency for some time until in 1837 a price of \$1 40 per ounce was reached. An upward movement then set in which, with an occasional relapse, as in 1842, carried the price to \$3 and upwards. The marked decline observable in 1857 was largely attributable to the abolition of the fifteen per cent. duty on cinchona barks. The rise in price from 1866 was due, primarily, of course, to the changed conditions arising from the civil war, including increased consumption, diminished supplies due to the perils of navigation incidental to the war, and an increased cost arising from these combined causes, and from the imposition of a high rate of duty, ranging up to forty-five per cent. for quinine itself, and twenty per cent. for the bark. The high range of prices continued to rule for some years, reaching the maximum of \$450 per ounce in 1877, since which time there has been a gradual decline to the present low value of nineteen cents for foreign bulk. At this juncture the influence of the East India barks began to be felt. In 1876 only 1,777 bales of this bark was imported into London, but the quantity rapidly increased to 6,260 in 1877, 13,460 in 1880, and 20,692 in 1881. In 1879 the alkaloid was also placed on the free list. It is this last

downward movement that has caused tremendous losses, and in many cases ruin, to those who have maintained faith in the market price of the article. The large deals, the excitement, and the final failures occurring when a price of \$3 was predicted as the bottom figure in 1880 and thereabouts, will no doubt be vividly remembered by many members of the trade.

A noteworthy feature of the market for large bulk here for some time past is the fact that our prices are below a parity with those quoted in London. There are several theories tenable as to the causes leading to this condition of affairs. One of these is that the foreign manufacturers use this market as dumping ground for their bulk goods, preferring to sell here when they find it necessary to realize, even at a little under current prices, rather than to demoralize the markets nearer their own houses. Another theory is to the effect that owing to the speculative spirit of Americans much larger quantities of quinine have been carried by outside speculators here than is the case in London. When one of these outside holders becomes disgusted and concludes to pocket his loss he is nearly always compelled to break the market in order to unload. Still another factor in the market is the change which has occurred in the method of handling the alkaloid. While physicians' prescriptions formerly offered an outlet for the bulk of the drug used, now the principal demand is from the public direct, who purchase the costed pills in bottles of 100 each. Where half a dozen or a dozen pills were formerly ordered by the physician; he now merely says "get a bottle of quinine pills," and as a consequence, the pill makers have come to be probably the largest purchasers of bulk goods, and purchasing in a large way, they came to be very close buyers. The gradual increase in the percentage yield of cinchona barks has also tended to reduce the cost of manufacture, and the heavy production of bark has kept the crude material at a low range of values for some time past.

With these agencies militating against an advance the future of the drug looks dull indeed, and it requires a sanguine disposition to be able to predict any material change for the better. It is true that a combination of the half dozen manufacturers might bring about higher prices, but in view of the attitude assumed by some of the largest manufacturers such a combination is scarcely to be counted among the immediate probabilities.—*Oil, Paint and Drug Reporter.*

A TALK ABOUT TEA.

(By the Pilgrim.)

The abnormal weather still seems the chief topic among my Assam correspondents. From Dibrugarh a friend writes, "I really believe it gets hotter every day instead of cooler. We are back again into the old blazing heat, and I am nearly done up. I have not felt the heat the whole season as much as I have done the last few days. There has not been a cloud in the sky for a week; the sun just blazes from 6 a.m. till 6 p.m."

Energetic rushes round the *Kanjari* are out of the question under such circumstances; and naturally there is a good deal of sickness amongst the coolies. It is very hard to get a full day's work out of them; the unusual heat disposes them to seek into shady spots under convenient trees whenever the "bois-eye" is off them.

From Nowgong it is the same story; everything very much in want of rain, and a very unhealthy season is the report. A correspondent writes: "Thermometer at 96° in the verandah today, and the whole place parched up." One of my Tezpur correspondents says: "The weather I registered in my last continued until the 23rd of September, when we had a fall of 1-11 inches, so we have now had 4-15 inches this month. This with a total of 5-99 inches for August, about beats the record. Surely we must have some rain to come yet: I am sure I hope so."

The most curious part of the matter is that, notwithstanding all this abnormal drought and heat,

outturn does not seem to be suffering, to any practical extent, so far, at least. The correspondents from whose letters I have quoted above seem all pretty happy on the subject of their crop for the season. The Dibrugarh man is keeping well up to a revised increased estimate; Nowgong smiles cheerfully as he says "done fairly well, nevertheless; over 300 maunds ahead of last year to date;" while my Tezpur friend talks of the sands in a lordly way, that takes the wind out of poor managers who struggle for tea and only mention hundreds when they are "balking" after dinner. A man who can make 1,800 maunds in a dry month like this September has been, who expected to close over 9,000 maunds, and who placidly remarks "that will average about 13½ maunds per acre"—such a man ought to filter out his information in instalments. It seems a size too large to grasp *en bloc*. I am very much afraid, however, that unless October turns out pretty wet which there seems very little chance of it doing at present, the dry weather and heat of the past month must tell; and a rapid decrease in outturn and an early "shut up" all round may be looked for.

Prices are very far from being a cheerful subject just now. It is significant of the state of the market that not a single garden in Assam and Cachar, and only one in Darjiling, set an average of two figures in last week's sales. There is only one garden in Darjiling which has scored up to eleven annas. And the solitary two figure Darjiling eleven anna average is contributed by Pekoo and broken Pekoo no lower class teas. The average of the sale appears to be about six annas, and this is not exhilarating. The home sales are a trifle more cheerful, and average of a shilling and a half-penny for Assam on 8,484 packages having been attained, and some marks, notably the well-known Jokai Company's Pantolla and Hakanpukri marks showing up gradually with averages of 2-4½ to 1½. Cachar and Sylhet do not come out so well, averaging, 8½d. for 3,701 packages. Darjiling, as usual, tops the list with 2,482 packages, averaging 1-3½.

One consolation, as I remarked in my last letter, is that if this extraordinary weather continues, and outturn consequently suffers, prices must surely rise, as supply will fall below estimates considerably. Every sorrow has its twin joy.

I see "Sam. Hogarth" is to the fore again on the labour question. He did yeoman's service in the "brutal planter and poor oppressed coolie" business a couple of years ago, when the Native press were suffering from an unusually severe spasm of righteous indignation; and his invitation to Gangooly Babu, the secretary to some Association whose angust designation I forget, to come and see things for himself choked that gentleman and his colleagues off for a while. I think this is "Sam's" first appearance in print since his return from his trip home. "More power to his elbow." If he can, by stirring up the Calcutta Tea Association, the Districts Labour Association, or any Association at all, only succeed in getting that wretched *arkatti* system of recruiting knocked on the head, he will deserve a statue opposite the Dibrugarh Club. I fear it is impossible, as has been attempted, to retain the system under proper checks and restriction; these look lovely on paper, but they don't work; and there is nothing for it but to abolish the *arkatti*, extirpate him root and branch, and rely upon *sindari* recruiting, pure and simple. There may be, undoubtedly there would be, a great deal of difficulty at first. Garden *sindars* sent down to recruit are often utterly unsuccessful; but that again is chiefly due to the objections of the *arkatti*. Labour must be had; and if *sindars* can't get it, it must be bought somehow. Mr. Hogarth in his para. 3 and the following one clearly shows the utterly objectionable points of the *arkatti* system, and the difficulties the *sindari* labours under, as opposed to him. His last paragraph, too, is deserving of most serious consideration. That this disgraceful system of "man selling" has grown up, and that the planter has to depend on it chiefly for his labour supply, is no fault of his, but is directly due to the native agitations against the then existing

recruiting system—a reasonable, humane, and generally smoothly working system—based on the recruit who had “been there,” been up and worked on the gardens, judged what the life was like and the probabilities of making “life worth living” as compared with life in his native village or elsewhere, and who went down to bring up his own family, relatives and friends, and their families, relatives and friends, as many as he could get. There was no abduction, crying, no “man selling,” only a plain statement of advantages to be gained by emigration, at worst slightly coloured by a sirdar eager to impress his relations and friends with the advantage of the change, and got his bonus per head for a large number of recruits. Put the coloring at its highest, after all, the sirdar was taking his own people to share a life that he had himself found by personal experience not only endurable, but profitable and pleasant, and the system forms a striking contrast to the *arkatti* one, which, with its attendant evils of misrepresentations, forcible abductions, and the general traffic in human flesh goes nearly to deserve the stigma of a “slave trade,” by which it was designated by a recent writer from the Madras side, when the Ganjan district was thrown open to coolie recruiting. It is to be hoped that Mr. Hogarth's effort will be seconded by united action on the part of the various associations concerned.—*Calcutta Englishman*.

HOW TO SAVE EXPENSE IN PAINTING UPON EXTERIOR SURFACES.

We always expect greater service than we receive from it because our system of exterior painting is a failure. It involves an actual loss each time of painting, of more than two hundred per cent., which in the aggregate for the entire country amounts to a positive loss of many millions of dollars by painting three times where once only is necessary.

This statement may appear exaggerated, nevertheless it is easily proven, as we shall show.

Such waste has been going on many years, and not unnoticed by property holders, but has been endured for the reason that no one has appeared who could solve this mystery. A discovery has been made and verified that by a very small extra expense, paint can be made to last three times as long as it has hitherto.

Experiments have been made with the various pigments, oils and vehicles employed for painting purposes, to ascertain which is the most durable; also the best method of applying it.

The most intricate problem becomes plain and simple, when understood, but without some knowledge of chemistry to enable us to see the various relations of cause and effect upon each other by these things, we cannot accomplish much. Object lessons are also helpful on our study as in this case it is so proved.

The exterior wall of a brick house in process of preparation to receive a coat of what is termed mastic finish attracted our attention. It was being covered with repeated coats of quick drying linseed oil until it became glossy, when the composition prepared with oil was spread with a trowel as plaster upon the surface.

It furnished the idea desired at once; this is the thing necessary to be done: Before painting prepare the surface by filling the pores or grain of the wood with quick oxidizing linseed oil for the support of the paint. Accordingly the experiment was made on a large scale and for a long period of ten years in the following order: The oxide of zinc was selected partly for its having been rejected for outside work by painters generally, on account of its cracking and peeling off, and partly for its being the oxide of a hard metal.

The best Calcutta raw linseed oil prepared with chemicals without heat to cause it to oxidize quickly and thus preserve its natural elasticity like oil when it begins to thicken was employed to coat the bare wood twice before painting, and when dry the same oil was used to mix the zinc, two coats of which was applied upon a large house so as to prepare a fair

opportunity for a test to all points of the compass during a period of ten years.

At the expiration of the tenth year on the side exposed to the South, the paint was somewhat bleached, but remained firm without signs of perishing, on the north side it had the appearance of withstanding another ten years test.

This oil possesses all the qualities of very old oil without the expense of storage and accumulation of interest for several years. A single coat of it over old paint is more durable than a coat of the process lead paint. Judging from these experiments it is very evident that we employ too little oil in painting on exteriors, and this is the true method of applying it for great durability.

The manufacturers of liquid mixed paints can now take advantage of this information and relieve their customers of an extraordinary expense from the sealing of their paints.

ASAHEL WHEELER.

—*Oil, Paint and Drug Reporter*.

A New Wood.—Western Australia is producing a wood which is destined to be much in favour with church builders. This is the jarrah wood, which is as hard and durable as oak, but possesses a rich, deep colour like mahogany or very old oak, and is well adapted for panelling and carving. Old Herno Church, in Kent—where the *Te Deum* was first sung in the English language—has just been re-roofed with jarrah, and the effect is said to be startlingly fine. The church is now completely restored.—*A. P. Press*.

The probability of large shipments of fruit's to this country, being made from our Australian Colonies in the early future, the practicability of which has been so recently demonstrated by the great quantities of excellent Tasmanian apples with which our markets have this year been supplied, is now further exemplified by the arrival of a small consignment of raisins from the Australian Irrigation Colonies, on the River Murray, being the first fruits received from these settlements, the establishment of which, some three or four years ago, has been attended with such remarkable success that their progress has been described by a colonial bishop who recently visited them—Dr. Thornton, of Ballarat—as simply “amazing.” A quantity of raisins are now on view at the London offices of the Australian Irrigation Colonies in Queen Victoria Street. They are entirely sun-dried, the clear dry atmosphere of that part of Australia where the settlements are situated enabling the drying of all descriptions of fruit to be carried out in the most perfect manner and without risk of injury. They have been pronounced of excellent quality, both in flavour and appearance, and are very attractively put up in 2 lb., 6 lb., and 12 lb. boxes. The above consignment will, in due course, be followed by others of a no less interesting character, embracing the following valuable fruits of commerce:—Oranges, lemons, raisins, currants, apricots, peaches, figs, &c., together with wine, olive oil, and other products, for which a large demand is anticipated in this country in future years. The total area of land constituting the Australian Irrigation Colonies, and of which some 25,000 acres at each of the two settlements (Mildura and Renmark) are now being dealt with will fall but little short of half a million acres; and although the colonial demand will probably absorb the entire production for some years—there being at present a large importation of these fruits, &c., into Australia from foreign countries—an extended reciprocal trade with the mother country will be early cultivated (more especially with reference to wine, oil, &c.), in view of the enormous future production which is confidently anticipated and practically assured.—*E. Mail*.

Correspondence.

To the Editor.

MR MAITLAND KIRWAN'S TEA PAPER.

Billiter Square Buildings,
London, E. C., Oct. 1st, 1891.

DEAR SIR,—I notice the attack made upon my paper linings by Messrs. W. H. Davies & Co., contained in their letter appearing in your overland issue of 4th September.

Wholesome criticism is good if based upon reasonable grounds, but that of Messrs. Davies & Co. appears to have for its foundation the views expressed in a letter to them of a London firm whose name is discreetly concealed. Two reasons are given for endeavouring to show why these linings are a "worthless article" for the purpose in view. *First*, because they are said to be porous, and *secondly*, the supposition that the trade would not give as good a price for tea packed thus, as for lead-lined packages.

With regard to the first of these reasons it appears to me that his proof of the pudding is in the eating, and we have now had these linings pretty extensively tried with complete success. The remarks in Messrs. Wilson, Smithett & Co.'s Circular from time to time respecting them and the testimony of those who have made trial of them ought I think to be the best proof of their efficacy in protecting and preserving the tea; and as regards the enclosed certificate from perhaps one of the highest authorities on these matters, may prove of interest to any who are still sceptical on this point.

As regards the second reason given for condemning the paper, I may say at once that it is not borne out by facts. It has been found that the trade buy the paper-lined packages as readily as the others, and so far from their giving a lower price, in some instances a farthing more has been secured; and I think I am justified in saying that since these new linings have been introduced there has been a distinct enquiry for teas packed thus, the opinion being that this paper obviates entirely the tinny flavor imparted to all teas to a more or less degree by the lead.

As to the perquisite obtained for the lead, the head partner of a large firm of grocers, with whom I conferred on this point some time ago laughingly assured me that if the quality of the tea was good there need be no fear on that score, and his words have been amply confirmed.

In conclusion let me say, that I am satisfied after repeated trials, that these linings are thoroughly suitable in every respect for the packing of tea; nevertheless I will always be grateful to receive suggestions which might in any way further that to perfect the articles.

With regard however to the wholesale attack made by Messrs. Davies & Co. on the linings, had this firm made trial of them and found them inadequate in preserving the tea, their letter would have assuredly deserved a hearing. As it is, doubtless their remarks will be received at their proper value.

It is I understand generally known that this firm are sellers of the tea lead, and it is not unnatural to suppose that they would dislike seeing any new article brought forward in competition therewith.—Your obedt. servant,

J. M. MAITLAND KIRWAN.

P. S.—Annexed is copy of letter received from the brokers relative to the last shipment in these linings, which speaks for itself.

Copy of letter received from Messrs. Wilson, Smithett & Co., re Paper Lining for Tea Ohests.

Dear Sir,—Referring to our Report on Elkadua Tea per "Goorkha" we notice that the Pekoe and Pekoe Souchong like the same grades in the "Bengal" shipment are packed in paper lined packages. We have carefully inspected all these teas and find them to be in excellent condition, the paper lining in each instance proving quite damp and air proof.—Yours faithfully,

(Signed) WILSON, SMITHETT & Co.

Messrs J. M. Kirwan & Co.

(Removed from 17, Bloomsbury Square.

Dr. Redwood, F. I. C., F. C. S., T. Horne Redwood, F. C. S., F. I. C., A. J. de Hailes, F. I. C., F. C. S., Analysts and Consulting Chemists.

2, Fisher Street, Red Lion Square, W.C.,
London, 30th Sept. 1891.

Messrs. J. M. Kirwan & Co., Billiter Square Buildings, London.

We hereby certify that we have tested the paper supplied by Messrs. J. M. Kirwan & Co., for the purpose of lining tea chests, and we have found it to be of a remarkably fine and pure quality. We are of opinion that it would preserve to the tea its delicate aroma without imparting any extraneous flavour.—T. HORNE REDWOOD, A. J. DE HAILES.

SUBSTITUTES FOR TEA LEAD.

61, Old Broad St., E. O.

DEAR SIR,—I have observed of late several articles and communications which have appeared in the columns of the *Ceylon Observer* and those of the *Tropical Agriculturist* touching upon the very great difficulty in the supplying of tea lead to Indian and Ceylon planters. As the writers point out, upon the proper solution of this difficulty, the price of tea in London markets is dependent to a very large extent; and its importance, in view of the remarkable growth of the Indian and Ceylon Tea trade, cannot very well be over-estimated. Suggestions have been made for the substitution for tea lead of parchment-prepared paper or an admixture of lead and paper; but while it is claimed for these substitutes that they answer as well as the lead and are to be had at a reduced cost, the advantages do not appear in practice to have made themselves particularly manifest. I have given the matter very careful consideration for some five years past, my attention having first been drawn to the subject at a time when the Indian tea trade had not attained to nearly its present proportions, and when the necessity for reducing the cost of the lead was not so apparent. The remarkable growth of the tea trade in India and Ceylon coupled with the demand for cheap tea in the London markets has however forced this question very specially upon my attention; and I feel that the time is ripe commercially for the submitting to those interested a practical method whereby the price of tea-lead to the Indian planters can be reduced considerably below its current price. My estimate is based upon personal knowledge of the lead supply and of the tea trade, and also upon the best practical advice as well as the published testimony of exports; and it is very far from being a sanguine one, for I have left the very widest margin for any difficulties which might by any possibility present themselves. I do not myself believe that any satisfactory substitute for tea-lead will be found, and I should like it to be clearly understood that I propose to supply the real article. My project aims solely at the reduction of the cost. In justice to myself however I cannot make this project public property, but as I

notice that the matter is engaging—as well it may—the earnest attention of the Ceylon Planters' Association, I have ventured to communicate to the Chairman of that Association my willingness, under certain guarantees, to disclose the nature of my project, perfectly assured that it only needs to be known to be understood and appreciated.—Yours truly,

W. G. CARDOZO.

INSECTS ATTACKING ACACIA MELANOXYLON.

Albion, Nuwara Eliya, Oct. 15th.

SIR,—On page 313 of the *Tropical Agriculturist* for November 1889, in Mr. Maiden's letter on Wattles, he mentions that "in Australia the wood of acacias is exceedingly liable to attacks by the larva of certain lepidoptera" &c., &c. By this post I send in a match box 2 small twigs of *Acacia melanoxylon* cut off and riddled by some poechiees, a few of which are still in the wood. Last week I cut down a five-year-old tree as it was looking sick; the accompanying is a specimen of the interior.—Yours faithfully,

ARTHUR KELLOW.

[Up till now we have never seen *Acacia melanoxylon* in Ceylon suffer from any pest except the parasitic *loranthus*, which could so easily be removed by a bamboo pole with a knife or sickle attached to the end, used for the clearing process. But there is no mistake as to the boring by insects of the specimen of wood from Mr. Kellow's five-year-old tree. We have submitted the twigs to our entomological referee, and he reports as follows:—"The numerous small holes in the wood are made by a minute boring beetle, name unknown to me. It probably feeds on the wood as it burrows. The female may lay its eggs in the burrow, and the larva undergo all its changes in it. I am unable to give its life history with any degree of certainty."—Ed. T. A.]

THE LOCAL vs. THE LONDON MARKET FOR TEA.

Central Province, Oct. 16th.

DEAR SIR,—Let me draw the attention of "Proprietor" to the memo. of Messrs. A. H. Thompson & Co. in the "Independent" and quoted in the *Overland Observer*, "Only 1,900 packages sold out of 4,523 offered." The Colombo broker thinks it necessary to account for this wonderful feature in our tiny market, and so he remarks: "The market was somewhat taxed by the unusual weight of the auctions; so a knock out practically occurred." "Buyers," he continues, "showed no inclination to buy except at very low rates." The wily Colombo buyer wanting to snaffle the grower's produce from 8 to 30c. under current value. Now let us turn to a circular issued by Messrs. Forbes & Walker. They state that the total sales in Colombo market to date come to 7,500,000 lb and the exports to Australia &c., reach 2,400,000 lb, so that about 5,000,000 lb. of the tea bought in local market goes to England, probably Mincing Lane. I know that some of that exported tea to other countries than England, never is handled by Colombo buyers, so I think I am giving the local market every justice in giving the buyers in it credit for having bought all the tea that is sent to foreign ports. By foreign I mean other than London.—Yours truly,

ONE WHO HAS TRIED BOTTL.

MR. KELLY'S TEA CROP ESTIMATES.

DEAR SIR,—Two things strike me as very strange in connection with Mr. Kelly's speech in Council, in reference to the tea crop of 1891.

If he put that crop at 140,000,000 lb. or double the 70,000,000 expected this year, how was it none of the papers challenged an estimate so rash, improbable, and calculated to do mischief? Our press is generally alive to its duty in such matters.

Then if Mr. Kelly did not speak of double 70,000,000 lb., but only of 120,000,000 lb., what have the reporters to say for themselves? I might also ask why Mr. Kelly was so slow about correcting a mistake of such magnitude—one so vital to our interests at a critical time and one so opposed to all inferences to be drawn from his Castlereagh Co.'s prospectus.

Our crop certainly shows a wonderful increase this year, but perhaps 5,000,000 lb. of it may be ascribed to the abnormal weather early in the year. To reach even 120,000,000 lb. in 1891 would mean yearly increases of 17,000,000 lb. a year:—in 1892 87,000,000 lb., in 1893 104,000,000 lb., and in 1891 120,000,000 lb.

Supposing we have 240,000 acres bearing in 1891, Mr. Kelly's estimate of 120,000,000 is an average of 500 lb. an acre. Is there any good reason to anticipate such an average? I think an estimate bearing the authority of the Committee of the Planters' Association would be of much service at this juncture. Nothing less will counteract the evil effects of the reported 140,000,000 lb., as that estimate will become current at home, while the correction to 120,000,000 lb. in a small para will pass unnoticed.—Yours,

INTERESTED.

[Mr. Kelly, in his desire to make out a strong case for the contribution of Ceylon tea to the British revenue, may have been over- sanguine in his estimate of 120,000,000 lb. for 1891. 100,000,000 would probably be nearer the mark.—Ed. T. A.]

THE TEA MARKETS OF THE WORLD.

Colombo, Oct. 24th.

DEAR SIR,—I am about to return to England after a stay of three months in your island, during which I have devoted my time to the study of tea manufacture, going into factories in the different districts, learning the process followed in each and comparing the results in the cup.

My visit has been happily timed, for I have come at a point where the many initial difficulties of a new enterprise being over come the minds of estate superintendents are free to consider details, and some after careful experiment have made great improvements in manufacture in the last twelve months. There are many however who have yet to learn what has been achieved and who continue on the old lines. We are all working together to open up new markets and especially to induce Continental Europe and America to drink Ceylon tea; and careful study and reflection teach me that that which will most assist towards this end is the new mode of preparation which may be described as "longer and harder rolling with shorter fermentation and with lower firing." With longer rolling a fuller liquor is obtained, the fruitiness of which is not impaired by the firing now approved, while the shorter fermentation imparts to the liquor more or less pungency and grip all according as the soil, climate and jāt will allow. Compared with China black tea, Ceylon and Indian teas have been marked by a harshness in addition to their meritorious qualities of strength and flavour, and it is to this harshness the

Russian buyers object. Now, we all wish to see the added millions of pounds of Ceylon tea go off each year without further fall in the London weekly average price, and a more general application of the new mode of preparation will assist the end in view. May I suggest, sir, that owners of gardens be asked to publish through your columns full details of manufacture; details of wither, of rolling, fermentation firing and sifting with percentage of each grade and prices obtained and that discussion by letter be invited; such comparison of results obtained over the whole tea area of the island could not fail to be of great value to each manufacturer.

No jealousies ought to arise—the crack gardens will not lose their stand out position because of a possible ten or fifteen per cent advance in other's prices due to improved make; indeed a general improvement in Ceylon teas would enhance the reputation of the best Ceylon gardens in the markets of the world.—I am, sir, with much respect, yours faithfully,

FRED. WALKER.

[We commend this letter of an experienced broker and tea taster to the best attention of planters; and we shall cordially welcome any communications on new and improved methods of manufacture, such as Mr. Walker suggests.—Ed. T. A.]

THE PROGRESS OF NETHERLANDS INDIA.—According to the Colonial Report for 1891, the population of natives in Java and Madura had at the end of 1889 increased to 22,806,433 souls, against 22,526,885 souls in 1888. The request made by planters in North Borneo for the immigration of labourers from Java could not be agreed to, owing to the unsatisfactory sanitary condition of Borneo and the considerable mortality among the foreign labourers on the possessions of the British North Borneo Company. Two deputies, charged with a mission, one to French Indo-China to study the existing system of opium, and the other to British India to inquire into the most suitable mode of transplanting sugar-cane, experienced the most ready support from the authorities. In West Java much inclination was shown to undertake a pilgrimage to Mecca, which, as far as it concerns the Prianger districts, proves a better financial position of the population, chiefly caused by the active trade in rice. With regard to Acheen the report observes that during the past year the resistance of the enemy has lost much of its power, which is merely to be ascribed to the blockade of the greater part of the north and west coast. The sanitary condition during 1890 was generally pretty favourable. The number of beriberi patients among the troops, of which the strength has not changed very much during last year, was in 1890 3,293, and thus larger than in 1889, when it was 2,637. However, the number is less than in the three preceding years. The *States Gazette* contains a statement of the principal articles of import and export to Java and Madura during the first six months of this year, compared with those of 1890, viz. :—

	1890	1891
	kilos.	kilos.
Indigo	997,918	1,221,293
Onchona Bark ...	1,913,430	1,262,231
Coffee	5,779,363	5,875,292
Pepper (black) ...	1,368,802	2,152,315
Sugar	98,054,896	143,342,389
Tobacco	9,987,879	10,301,489
Tea	1,571,913	1,722,903
Tin	2,206,747	2,615,189
Snndries	1,663,627	5,024,969

The above shows generally a considerable increase, but a decrease is exhibited in the following table :—

	1890	1891
	kilos.	kilos.
Hides	1,262,705	1,209,573
Kapok	1,122,745	1,070,657
Rattans	579,760	851,297

—*L. and C. Express.*

MESSRS. DAVIDSON & Co.'s CENTRAL FACTORY, COLOMBO.—The local "Times" says that Messrs. Davidson & Company Belfast have at length decided to start a workshop in Colombo with the view of providing skilled superintendence for the erection of any of their machines upcountry and to provide a proper and efficient means of repairing, altering, and correcting any mistakes complained of in regard to their several inventions. Messrs. Davidson & Company have obtained a portion of Messrs. Mackwood & Co.'s Mills at Suduwolle for the purpose, and Mr. Maguire, who will now reside here permanently, will be put in charge of the necessary machinery, plant, stock, &c.; and all castings of the machines and plates and so on will be sent out from home, while, whenever a new machine has been erected upcountry, Mr. Maguire himself will proceed to the estate and see it put together. This will be a great advantage to planters who intend going in for the down draft Sirecco, and may be taken as evidence of the large demand which Messrs. Davidson & Co., foresee for their new machines.

A CORRESPONDENT sends the following interesting note :—"A few months ago a new theory was put forward respecting the origin and nature of the moisture found in the morning on leaves and grass. It has hitherto been held by all naturalists, apparently without exception, that this moisture was dew. But a gentleman in Scotland, not known to fame, was not content to accept the current and traditional opinion; and assuming nothing, he investigated the subject *de novo*, with the result that he was able to prove to demonstration that between the dew and the moisture found after a rainless night on vegetation there was an essential difference. He discovered that while dew is but the mere exhalation of the soil, this moisture was an exhalation from the vegetation itself. The theory came as a surprise to the scientific world; but the steps of the demonstration were so clearly worked out that the author of the discovery, though not noted as a man of science, was at once brought into public notice. He was held by the highest scientific authorities to have made a distinct discovery in nature. Now, there are some phenomena not mentioned by him which appear undoubtedly to bear out his theory on the subject, and they may be noted at the present time, because they are patent to the observation of us all at this time of the year. Let a tree overhang a white washed wall or gateway, and in course of time we shall see the white-wash is covered with green film. On the time honoured theory that the moisture on leaves was but the exhalation which had risen from the soil during the previous night, it was impossible to account for the colour of this deposit. Mere water would not have produced the phenomenon. The only adequate theory is that the moisture which fell upon the whitewash was chemically a green composition. The theory is further corroborated from the curious fact, equally near at hand to us all, that after a rainless night *mendhi* that was out on the previous day and is now entirely without green leaves, is dry, while the *mendhi* which is budding and that which has leaves is saturated with moisture. A servant after such a night will without hesitation put an article of clothing to air in the sun on *mendhi* so recently out, though he would deem it the height of folly to place it on green *mendhi* for that purpose. There were two points which first awakened the attention of the discoverer to the subject: the first was, that moisture was found on the under surface of the leaves as well as on the upper; and the second, that moisture was found on the leaves after nights in which no dew had fallen, phenomena for the presence of which the old-world theory provided no satisfactory explanation."—*Indian Agriculturist*, Sept. 26th.

QUININE.—The market remains dull, but at the close of last week a small transaction in second-hand German bark at 9½d per oz was reported. Since then business has been suspended in anticipation of the result of today's work sales in Amsterdam. On September 25th one of the German "speculative" brands was being offered in New York by the manufacturer at 19½ cents (9½d per lb.) for contracts all over 1891. That manufacturer certainly does not entertain sanguine views with regard to the future of the article. The following are the manufacturers' present quotations:—Howard's, in tins, 1s 1d to 1s 3d; in vials, 1s 3d to 1s 4d; Whiffen's, in tins, 1s 1d; in vials, 1s 3d; Pelletier's in vials, 1s 10d; Milan in vials, 1s 2d; in tins, 1s; Zimmer and Jobst, in tins, 11½d; other German brands, in tins, 10½d per oz.—*Chemist and Druggist*, Oct. 10th.

CINCHONA.—Having regard to the meagreness of our bark sales of late, the supply of nearly 1,500 packages this week seemed almost abundant. The quality of the bark offered, too, was superior to what our buyers have had to content themselves with lately. The catalogue consisted of

	Pkgs.		Pkgs.
Ceylon bark	1,001	of which	1,001 were sold
Indian bark	138	"	105 "
Java bark	84	"	74 "
South American bark	214	"	5 "
Total	1,437	"	1,885 "

There was a very fair demand throughout the motions, in which the majority of the manufacturers' agents participated, and with steady competition all the Ceylon as well as the bulk of the Indian and Java barks were disposed of at an average unit of 1½d per lb. for good manufacturing barks.

The following are the approximate quantities purchased by the principal buyers:—

	lbs.
Agents for the Mennheim and Amsterdam works	67,15
Auerbach factory	55,687
Messrs. Howard's & Sons	46,303
Agents for the Frankfurt of M. and Stuttgart works	42,755
Brunswick works	29,150
American and Italian works	26,910
Sundry druggists	10,189
Total quantity of bark sold	278,150
Bought in or withdrawn	53,870
Total quantity of bark offered	332,020

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots, and *vice versa*. The following prices are shown by an analysis of the catalogues to have been paid for sound bark:—

CEYLON CINCHONA.—Original:—Red varieties, ordinary woody to good bright stem and branch chips, 1½d to 3d; a few fine lots, 4d; dust, 1d; dusty root, 2d; ordinary weak quill, 3d; fair to fine bright spokes shavings, 1½d to 4d per lb. Yellow varieties, common to good bright quilly Ledger chips, 1½d to 4d per lb. Yellow varieties, common to good bright quilly ledger chips, 1½d to 6½d; good to fine bright shavings, 4d to 7d; dull root, 3d ordinary Cabasa chips, 2½d to 2½d; root, 3d per lb. Grey varieties, ordinary dull to good bright quilly branch and stem chips, 1½d to 5½d; fair to good root, 3d to 5½d per lb. Hybrid chips, 1½d to 4d; root, 3½d to 4d; shavings, 2½d to 5½d per lb. Renewed: Red varieties good to very fine rich shavings 3½d to 6½d; poor to good stem and branch chips, 1½d to 3½d good quilly chips, 4d per lb. Yellow common chips, 3½d; fair shavings, 6½d to 6½d per lb. Grey varieties, poor to good quilly stem and branch chips, 2½d to 5½d per lb. Hybrid dusty to fair stem and branch chips, 2½d to 4½d per lb.

It is mentioned in connection with the Gibbs Dryer and patent Filter Stoves, that the tea from the gardens of the Jokai Assam Tea Company, Limited, which fetched the top price in the "Lancet," were passed through these dryers, and that the fermentation was fixed by these machines.—*Home and Colonial Mail*.

MR. BARTON'S TEA DISEASE, for which he was to provide "a perfect cure," turns out, as we expected, to be a case of much ado about nothing. Trees badly planted in shallow holes with their roots turned up, cannot make healthy growth and in shallow and moistureless soil, even tea cannot enjoy a healthy existence,—that is all. In such large expanses of tea as exist in Ceylon, some bad planting in good soil and some planting in unsuitable soil is inevitable and so there are some unhealthy plants on every estate, apart from those affected by *synchytrium* fungus. Dr. Trimen's deliverance on the subject, as conveyed in response to queries from the "Independent" editor, is as follows:—

The leaves at the ends of the shoots are dry, often puckered and torn, yellowish, discoloured with brown spots and lues, and they seem to ultimately dry completely and fall off. The twigs become dry and are often quite dead at their summit; lower down, though apparently healthy outside, the young wood and inner bark show a brown discoloration and decay. Such appearances might be due to the ravages of a sucking insect, but I see no trace of any. Fortunately our Ceylon species of *Helopeltis* does not seem to attack tea. The brown discolorations of the leaves are not at all like those produced by any parasitic fungus, nor is any such to be discovered on them. I cannot find any web of red spider or any other trace of that insect.

The appearances clearly point to some failure in root action, and that this is their cause is probable from an examination of the roots sent.

In the larger bush (No. 1) which is apparently a "stump" with a main stem nearly 7 in. in circumference, the large tap root is, at a distance of less than 8 inches below the collar, bent at right angles, and runs horizontally for 3 feet, at which length it has been out off in digging the plant. Just below the crown, there are many other horizontal branches also spreading out to as great a length laterally as the tap root, and like it out off.

In the smaller bush (No. 2) the state of things is not so bad, the tap root extending downwards for 12 inches, and then branching horizontally; in this also there are a large number of thick spreading horizontal branches immediately below the surface of the ground.

This state of the roots is such as should be found in no tea bush grown under proper favourable conditions, and shows conclusively that the plant is unable to obtain a sufficient supply of food, and specially of water. These two bushes must have been planted in soil far too shallow for so deep rooted a plant as tea.

The cases before me then are practically cases of starvation, and want of sufficient water to supply the evaporation from the leaves. I see in them no evidence of disease in any other sense than this. The condition of the bushes is individual to each, and has nothing of an epidemic character.

I am, of course, able to speak only as to the material before me. The minute rootlets have necessarily been all destroyed in removing the soil, and I am thus unable to say whether the condition is aggravated by "grub," but it is fully explained by the evidence of unsuitable conditions supplied by the roots.

The real cause is careless planting. Tea should never be put out in places where there is no possibility of its tap root taking its natural direction, though of course something may be done by cutting it off. I am sure, too, that coolies very often turn the root up by planting in holes that are too shallow. Tea is a very hardy plant; but it feels drought, and in our hot, sunny climate, the root-system must be largely developed to supply the great evaporation.

METEOROLOGY IN INDIA.

As we pointed out not long ago, the Meteorological Department has given its unreserved admission to the truth insisted upon, some months since, in these columns, that India is not, as was supposed till very recently, a kind of meteorological *imperium in imperio*—or, as the monograph just published by the Department puts it—"a self-contained meteorological region cut off from Central Asia, etc., by the high mountains in the north-east, north and north-west, and from the rest of the world by a belt of calm, or doldrums, running along the Equator from Sumatra to Africa." Correspondences in meteorological conditions too well certified to be questioned, and too numerous to be referred to mere coincidence for an explanation, establish beyond doubt the existence of an intimate relationship between the weather of the Indian peninsula, and that of regions far beyond these barriers; but how far this connexion is the result of a direct relationship of cause and effect between the observed phenomena, and how far of their relationship to some common cause lying outside the limits of observation, still remains to be determined. The probability, we think, is that both kinds of relationship come into play—in other words, that there is direct interaction between the weather phenomena of these remote parts, as indeed there no doubt is, in some degree or other between all the parts of the world's atmosphere, and that they are also subject to the common influence of some more general cause. Looking, however, at the formidable character of the barriers referred to, the probability seems to be that it is to a relationship of the latter kind that the observed correspondences are mainly due, and that direct interaction between changes occurring in the weather of the Indian peninsula and that of trans-Himalayan or trans-Equatorial regions plays an altogether subsidiary part in their genesis. One of the great defects of existing meteorological theory, is the extent to which it ignores the movements and other physical conditions of the upper regions of the atmosphere. The defect itself is no doubt largely due to the extremely limited character of the opportunities that have hitherto existed for observing these changes and conditions; and its removal must depend to a great extent on their multiplication in the future. Of the larger movements of the atmosphere at high altitudes, we possess indeed a certain measure of theoretical knowledge, based partly on inference from what we know regarding the motion of the earth; and we are also able, by calculation, to arrive at rough conclusions regarding the general temperature of the atmosphere at different altitudes. As a means of supplementing and checking the former knowledge, we have, too, the observed movements of the clouds in regions beyond the reach of the anemometer, though these, after all, do not carry us very far. But the information derived from all these sources put together falls very far short of what is needed to make meteorology anything like an exact science. Without accepting M. Faye's theory of the origin of cyclones, which are probably not all due to the same cause, it may be regarded as almost certain that many, if not most, of the more violent of these phenomena originate in movements in the upper regions of the atmosphere; for it is in those regions that the normal movements of the air are most rapid, reaching a velocity, there is reason to believe, of as much as eighty or even a hundred miles an hour, and it is there, consequently, that the whirls produced by the mutual impact of currents moving in different directions are likely to develop the most formidable proportions. That such atmospheric whirlpools can persist for any

length of time without affecting the air near the earth's surface, is in the highest degree improbable, and there is a great deal of an *a priori* character to be urged in favour of M. Faye's view that they must often propagate themselves downward until they actually touch bottom on the solid substance of the globe. The incontinent development, moreover, of circumscribed areas of low pressure at the earth's surface, and their long continued persistence often in the entire absence of horizontal movement, and in the presence of conditions under which according to all known physical laws, they should rapidly fill up and disappear, presents a mystery which meteorology has, so far, utterly failed to solve; but which would probably vanish if their connexion with movements in the upper regions of the atmosphere were recognised. Nor is it only such violent meteorological convulsions as cyclones that are probably traceable to changes taking place at altitudes beyond the reach of observation. There is every reason to believe, for instance, that sudden depression of the temperature at the earth's surface are, in many cases, caused not by a lateral inflow of cold air, but by the descent of a body of such air from above. The common phenomenon of an absolutely, or comparatively, clear sky becoming overcast, sometimes with great rapidity, by clouds which seem to come from nowhere, and which are obviously not brought in laterally from adjacent regions, is, no doubt, due to such a movement; the cloud being really formed *in situ* as a result of the condensation, by the down rush of cold air, of vapour suspended in the atmosphere which was previously invisible. What is needed to give greater coherence to our meteorological knowledge, and to confer greater certainty on our weather forecasts, is not merely the multiplication of recording stations at or near sea level, but, in an even greater degree, their establishment on mountain heights, and the discovery, if that be possible, of some means of systematically observing and recording the atmospheric changes which take place in regions unpenetrated by mountain tops and inaccessible to balloons.—*Indian Agriculturist.*

THE RIVAL GLASGOW TEA DEALERS.

Mr. Cranston has reprinted a notice of himself and his tea rooms from a humorous periodical called "The Bailie," which depicts him as a great friend of temperance and practically a tea-totaler. Mr. Cranston deals chiefly in China teas, and according to "The Bailie,"

One of his pet subjects, is the contrast between the "bitter" and the "mild" species of the fragrant herb. The strong, pungent Indian teas, he points out, yield, when infused, 9 per cent of tannin, as against 3 per cent given out by the milder teas of the Chinese Empire, and yet, he adds, the yield of theme from both is practically the same.

Our readers need scarcely be informed that tea without a good proportion of tannin is poor stuff. Mr. Cranston boasts that

£1,024: 18: 4

is the actual first cost price of our first purchase of New Season's Tea, consisting of one invoice for 142 Half Chests Finest Kintook Mouing, at 2/4 per pound, duty paid.

We are informed that this is the biggest "obop" and largest purchase of China Tea at the price in one line that has been effected in the West of Scotland for ten years back—"wholesale houses" even not excluded.

It would be an act of vandalism to mix this exquisite China Tea along with those strong, dark, bitter Indian

and Ceylon Teas, which yield so much Tannin and are so injurious to the system; and if the present generation would drink this China Tea—without cream or sugar—they would appreciate the old praises of "old fashioned" Tea as sung by their grandmothers, and at the same time be free from dyspepsia.

After this false rubbish Mr. Cranston goes mad and raves thus;—

It is not so much a question that China Tea has fallen off in quality (not quantity) as that the public taste has become demoralised and vitiated by believing in and buying upon the faith of lying advertisements; for instance, that deliberate falsehood which reads, "Extra Choicest Indian and Ceylon Blend, 1/7 per pound. The finest the world can produce. Direct from the Tea Gardens to the Teapot."

We prove the falsehood by offering our own Blend of Indian, Ceylon and China Tea at 1/6, which we guarantee to be of finer flavour and quality, and more refreshing to the system.

We challenge this unscrupulous Advertiser to contradict—if he dare—our statement that the greater portion of the Tea he sells is *not* grown upon his own estates, but is bought at Public Auction on the London market.

He pays large salaries to buyers and assistants, and high rents for offices and stores, while we pay not one penny beyond a bare commission on public sale prices, and we believe our cost price is considerably lower than his.

We have the cream of the market to select from, and we sell at *one-half* the profit exacted by firms in London, Edinburgh and Glasgow who make the loudest pretensions under cover of that much abused phrase "Wholesale Rates." Therefore, our Teas defy such competition.

Note our Prices for Mild and Refreshing Blends of Indian, Ceylon and China Tea.

1/4, 1/3, 1/6, 1/9, 2/3, 2/6 per lb. and upwards.

Pure Darjeeling 1/9, 2/3, 3/4 and 3/3.

Pure Ceylon 1/3, 1/9, 2/3 and 2/6.

Pure China 1/6, 2/3 and 2/9.

Our readers will notice that this man assigns a position to Ceylon tea below China, the reason, probably, we may with no lack of charity guess to be, that his rival is interested in Ceylon tea.

IN A TEA WAREHOUSE.

A VICE-REGAL VISIT.

A vice-regal party, consisting of the Governor and Lady Jersey, accompanied by Captain Cholmondeley, one of the aides-de-camp, paid a visit yesterday to the warehouse of Messrs. James Inglis & Co., tea merchants, in Dean's place. Received at the door by Mr. Inglis, M.P., the party proceeded upstairs to the salerooms and where a tea plant was to be seen, where the centre table and the walls were covered with photographs showing every process through which the plant goes, from the primary cultivation to the gathering and fermentation and packing of the leaf. Nearly every variety of tea was on view here. There were neat wooden packages from Java, the stronger teak wood and mango wood, and lead-lined packages from Ceylon and India, and the patty caned packages from China and Japan. A well-grown specimen of hybrid tea from Mr. Inglis' own Indian conservatory was on the table. Mr. Inglis himself acted as guide, and displayed a number of excellent photographs, showing the successive stages of the growth, picking and manufacture of the plant.

Lady Jersey expressed some surprise at hearing that tea had to be fermented before it is of any value as a marketable commodity.

"The fact is not generally known," says Mr. Inglis, "but it is so notwithstanding. Tea has always to be fermented before it is any good. Then it is bruised,

rolled by machinery, then separated into different grades and afterwards packed."

"But there is a difference between the number of pickings as regards India and China tea, is there not?" asks Lord Jersey, as he takes a haudful from a chest and buries his nose in it.

"A marked difference," replies the indefatigable guide. "In China there are only about three pickings a year. They are known as the first, second and third crop. But owing to the more scientific method of cultivation in India and Ceylon and the system of pruning and manuring which is adopted some gardens there give actually from 12 to 16 pickings per annum. These pickings are known as flushes, and at the annual sorting up of the garden all coarse and decayed wood is pruned out. Indeed the knife is employed most ruthlessly to stimulate as far as possible the growth of the fresh young wood, from which the finest kinds of tea are taken."

"But how do you get this remarkably £85 a pound tea which we have heard something of lately?" asks the Governor.

"The reported high price is probably a trade advertisement," says the pilot. "It is altogether excessive, entirely beyond the real value of the article. Still, it is extremely expensive for all that. Now look at this living plant here," he continues, taking the growing article from the table. "Just at the top is this small delicate leaf. These leaves are called the tippy buds. If you closely examine them you will notice that they are covered with a fine delicate hairy growth much like that which we find on a butterfly's wings. These are scattered through a mass of common tea, and the value of the tea itself is calculated according to the proportion of tip which it contains. A very tippy tea gives a greater flavor and commands a much higher price than tea destitute of the tip. How do you select the tip from the other leaf? In this way. A piece of fine tannin is spread on a mass of tea. The hairy little golden tips stick to it, and if the process be continued a large quantity of pure tip can be separated from the common article. In this way the very finest samples of golden tip can be procured. It is no doubt this which has gained the fabulous prices which are said to have recently been obtained in London."

"What varieties are there of tea?" inquired Lady Jersey.

"Pekoe is the fine tip, Souchong is the large leaf further down the stem and Congou is the leathery, woody leaf. Congou is the synonym for the people's tea. It is the tea drunk by the common people. Pekoe Souchong is a mixture of the very fine with the ordinary leaf, and Oolong, Kooloo and other well-known varieties take their names from peculiarities of manufacture or from the names of the district in which they are grown. Fanyang, Sneykent Saryung, Darjeeling, Assam and Sythee"—and as he ran off this list of jaw-breaking names the guide pointed to the samples around the saleroom—"are all names derived from the district where the plant is cultivated. The Fochow district produces the largest quantity of tea in use in Australasia. The green teas are used in America, they come principally from Japan, Formosa and Fochow. From Hankow the black leaf teas known as the Monings go to London and Russia. In Canton and Facao, which are southern parts, the crop ripens fully six months earlier than it does in the more northern latitudes, and the teas which come thence are known as the 'new makes.' The bulk of the scented teas are procured from the same localities. The Houg Mee, a flowery tea, is obtained from Canton. What is known as the scent is really an article foreign to the tea plant altogether. It is generally made from the very delicately-scented *Jasminum Sambac*. By Chinamee it is called Po-oo. It is simply the powder of the

* Our good friend Mr. Inglis did not, we feel certain, give the sequence as represented by the reporter, but put the rolling and bruising before what is unfortunately called fermentation.—[Ed. T. J.]

jasmine flower, which is liberally dusted over the teas." Having listened with bated breath and whispering humbly to this disquisition, the party makes a move in the direction of the packing department, passing on the way through storerooms loaded up with every description and brand of tea from everywhere from Java to China. In the packingroom are a number of girls and young women busily engaged at desks examining the blendol tea in packets, according to the brand which it is intended to send them out to the public. The expeditious manner in which they go through their work is astonishing. Some make the packets, gauged to hold exactly a pound in weight, others distribute them along the tables, others again take them up, fill them with the loaded pound gauge and then force in the tea with a wooden article specially made for the purpose. After the receptacles are filled their duty is to remove the outer case, seal up the packet, and then it is ready for the market. Some statements are made by the girls as to how much they can earn at the work. Some say 25s, others 30s, others 40s, while one stated that she has earned as much as £3.

"I wonder what sort of success I would attain at it," says Lady Jersey, as she takes hold of a packet and tries to remove it from the outer casing.

"I'll keep time," remarks Mr. Bruce Smith, who has just joined the party and who pulls out his watch for the purpose. Mr. Bruce Smith is apparently a dab at this kind of thing.

Lady Jersey makes several gallant efforts to get through the work. She is about as successful as a "labor" bill is in getting through the Council.

"How much could I earn?" she asks, when the fruitless effort is over.

"Exactly 4d a month!" replied the Treasurer, who has gauged the matter to a nicety.

In the meantime Mr. Inglis is looking for an opportunity to open the flood gates of information on the tea industry generally. A question as to the progress of the Indian trade gives him the opportunity.

"Ceylon has grown up since 1880 from an export of 23lb. to 50,000,000 lb. It was over 40,000,000 lb. last year, and I think that this year will give an additional 10,000,000." * The progress of the Indian tea trade has been one of the commercial phenomena of the century. The Indian teas have greater body, and are invaluable in many respects for their exhilarating qualities. They are specially adopted for blending with the more delicate China teas; for Indian tea is to China what good beer is to the finest light claret."

Mr. Rowbotham, who is an expert, also furnishes much useful information and says that if he could only get the right sort of labor he could grow enough tea on the northern rivers of this colony to supply the world. The Australian and New Hebrides Company, of which Mr. Inglis is one of the directors has established extensive plantations in Fiji for the cultivation of tea, and a little has been grown by retired Anglo-Indians on the north-west coast of Tasmania. The process of tea tasting is explained, some experiments are made and the visit is over.—*Sydney Daily Telegraph*, Oct. 3rd.

JAMAICA PRODUCTS.—Writing of the Imperial Institute the Jamaica *Gleaner* states:—

An Exchange in London where all, and that not by any means a little, that Jamaica can produce will be exhibited, is an advantage so obvious, an opportunity so fruitful of benefits, as to be self-demonstrable. In addition to our well known Staples, Rum, Sugar, Coffee, our list of special and of new exports is a large one, including Fruit, Pimento, Logwood, Fibres of all kinds, Fancy woods. To these may be added Sarsaparilla, Cinchona, Cacao, Kola, Anatto, Wax, Our ochrea and e ays, as yet little known, have been pronounced by competent judges, equal to any in the world.

* By the middle of October the figure was 54 millions.—*Ed. T. A.*

THE *Eaglehawk* correspondent of the *Bendigo Independent* writes:—"I was shown a Yaukece specimen of ingenuity and simplicity. It was a 'post hole digger,' and was imported from America. It will dig from 200 to 300 holes per day in any ordinary ground, with only a novice in charge of it. The 'digger' is a steel cone of 15 inches length and 7 1/2 inches in diameter, with an iron pipe or cylinder 3 feet in length attached to the top. In this cylinder a strong iron rod 4 feet in length is worked, called the driving rod. It strikes on a cap of hard leather on the top of the cone, which can be easily replaced at any time. There are two small handles at the top of the cylinder to lift it with. The cone is placed where the hole is sunk, and the rod is worked smartly up and down, sinking the cone into the earth, a slight pull and push being given every second or third blow to the handle, as would be done with a chisel in cutting a mortar. The digger takes about 6 inches of earth in each cut. At a trial on a hard pa hway, a round hole 8 inches in diameter was sunk 2 feet 5 inches in five minutes and a half. Another trial was then made, with even better results. The 'digger' will prove a useful instrument on the plains, or on ground that is not very strong. The holes are quickly made, and not much 'packing' is required, the posts in most instances about filling the holes. The weight of the instrument is about 60lb., and, being all steel and iron, cannot be easily broken or injured." Some modification of this implement might serve for making holes for vine or tree planting.—*Mildura Cultivator*.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE, COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for November:—

OCCASIONAL NOTES.

It has already been announced by the daily papers, 3,000 copies of the first Agricultural Information Leaflet were circulated. So far as circulation goes the promoters of the project of issuing these leaflets may congratulate themselves on its success. Up to date orders have been received for over 3,000 copies each month, and these from the "Sinhalese" provinces only. Great help in the matter of circulation has been given by Government officials, schoolmasters, agricultural instructors, private landowners, and in fact all classes, who have given orders of from 1 to 100 each, and promised to take advantage of land sales and other large gatherings, journeys through the villages, schools and such means which facilitate distribution. It is satisfactory to note that even the modest charge of 1 cent per copy will seldom be incurred by the goiyas themselves, to whom the information given is offered in as simple a form as possible. Under existing circumstances the best available means for circulating agricultural leaflets have been secured, and though it might be considered by some that a more perfect method for their circulation can be adopted, the fact remains that the utmost has been done that can be done, and that as a private enterprise the project has met with as much success as can be expected. With their present circulation, and considering the support given to the leaflets, it will be surprising if the information they embody does not reach almost every cultivator in the Sinhalese Provinces.

It is a matter of great urgency that a spraying machine—a modified form of the Strawsoniser should be secured by the Government for special use in paddy-fields infested by insect pests—in the

interests of the paddy cultivator as well as in its own interests, inasmuch as a reduced yield of paddy means a reduced income to the Government. If someone thoroughly acquainted with the peculiar conditions under which paddy is cultivated be deputed to arrange with the manufacturers of these spraying machines to construct one suitable for use on paddy land, there should be no difficulty in getting the desired machine. Dr. Neal, the entomologist, says that nothing has been done in practical entomology that has shown better results than the use of emulsions containing kerosine or insoluble poison held in suspension, and their application to infected plants in a fine spray by various atomisers and spray pumps." With one of these machines, an insecticide can be brought in contact with an insect, and its feeding ground thoroughly impregnated with poison. It is needful that the spray be very fine, and that it be applied with force to reach every infected part, or the hiding-places of insects.

The Report of the Director of Public Instruction for 1890 contains an unusually short reference to the Colombo School of Agriculture, "which continues to fulfil," the Director is glad to say, "the expectations of my predecessor." A detailed report of the work of the school was read on prize-day last December, and reproduced in the Magazine columns. It was only late in 1890 that Mr. Cull succeeded Mr. Green, and the new Director will no doubt have more to say of the school in his report for 1891, which has so far proved, in many ways, an eventful and "lucky" year for the Institution.

We have pleasure in announcing that the stud bull which was expected from India has safely arrived. The bull (which was one of the Saidapot farm stock) is a handsome and compact animal, and well-suited for the object it was intended, namely, of mating with native cattle, and thus improving the breed. We trust advantage will be taken of the facilities offered to native cattle-owners to improve their stock.

The Director of the Colombo Museum in his last report mentions that carbolicised oil is one of the most powerful preservatives known both for form and colour. Coconut oil and carbolic acid are said to mix freely in all proportions. The acid moreover enables coconut oil and turpentine to be mixed, the mixture forming a splendid microscopic fluid.

The idea of appointing a veterinary officer to Colombo, (which we believe originated with H. E. the Governor), and our recommendation that he should be attached as a lecturer to the School of Agriculture, are, we are glad to say, about to be carried into effect. In the Supply Bill for next year, a sum of R5,000 has been provided for veterinary work. We understand it is contemplated to erect a veterinary hospital on the School of Agriculture premises, so that the need for more groundspace for additions to the present buildings will be opportunely met by the grant of land lately made to the school.

Miss Ormerod, the distinguished authoress of the "Manual of Injurious Insects," has decided to resign her appointment as Consulting Entomologist to the Royal Agricultural Society, owing to the scant courtesy which she has received at the hands of that body. Miss Ormerod does not, however, mean to abandon her entomological work which she has carried on for the last fourteen years, and hopes "to be permitted the pleasure still of being consulted, and of replying to enquiries just as before," that is privately.

We have perused with pleasure the report of the Government Agent, Amradhapura, as published by the *Hindu Organ*, embodying a scheme for the colonisation of Kalawewa, which is said to have the sanction of Government. The scheme is evidently the outcome of much deliberation, being based on liberal and philanthropic—and at the same time strict—principles, and we shall anxiously look forward to its being carried out into practice.

Mr. Millson, Assistant Colonial Secretary of Lagos, in his report on the indigenous plants of Yoruba-land, says that sorghom vulgare, which he calls red guinea corn, is not cultivated for the grain which is not used, but as a dye plant—the dye being described as excellent. Sorghum vulgare is the Indian cholom.

The rain-making experiments made by Colonel Dyrenforth, of the United States Agricultural Department, may be said to have been a success. The value of the discovery will depend on the expense which the process of rain making involves, and the possibility of its use in practical agriculture.

GAS LIME FOR CLAY SOIL.—In his article in the Royal Society's *Journal* on the 'Experiences of a Scotsman on the Essex Clays,' Professor McConnell writes as follows:—"The action of lime on a clay soil is well known, and in this district we use immense quantities of the spent lime from the London gas-works, which we get at the cost of the carriage. It is applied in various ways, and many are foolish enough to use it without manure.

We have applied it raw to the coarse parts of pasture lands, but it seemed to make them still coarser, at least during the first year. Some mix it with earth for compost for top-dressings, and some apply it to the fallows. We prefer to apply it raw, at the rate of from 4 to 6 tons per acre in autumn, to the lea land that is to be ploughed up during the winter. By this means all grubs are killed, the turf is partly killed, the soil is made more friable, while of course, the natural fertility is stimulated. By itself, I have seen it act on a crop as strongly as nitrate of soda, but the soil must be fed along with it. Its effect on the mechanical texture of the soil is wonderful. I remember one case of a field that was partly dressed and partly left undressed with it, and in broadcasting the seed afterwards, I could feel the difference in the soil in stepping from the one part to the other, every time I went up and down the stetches, because the limed part was so much more loose and friable. Some maintain that it does no good to the soil, either mechanically or manurally, but we would not like to farm without it here. Of course, the land is ready for a fresh dressing every time the grass is ploughed up. I have not seen the crop killed by as much as 6 tons per acre, while, even on the permanent pasture land, 3 or 4 tons put on raw did not do any injury in this way. There are two varieties of this spent lime used here—the blue and the white. It is generally understood that the former is more poisonous than the latter, from having been used longer in purifying the gas; but for this reason, it is more effectual in its action, and its poisonous sulphites are oxidised long before the crop is sown." This suggested the question, what is done with the gas-lime produced at our local gas-works?

We have to acknowledge with thanks the receipt of the Richmond College Magazine, Ceylon Patriot, Hindu Organ, and St. Thomas' College Magazine.

CULTIVATION OF THE COCONUT PALM.

The proper month for transplanting in sandy or dry land is in November or at the beginning of the rains, as no watering need then be done till the rains are over. In low marshy situations it is safer to plant after the rains. As they grow the plants must be watered whenever necessary, and a sharp lookout kept for the coconut beetles, which invariably attack and often kill young plants, and even young bearing trees. These pests are common enough in every new plantation, but are specially plentiful on estates where the felled jungle consisted to a large extent of the wild mango, a very common tree in the Eastern Province. It has been a moot point whether it is better to thoroughly clear and stub a new plantation, or to allow the stumps of forest trees and dead wood to remain on the ground to decay and crumble down in the course of time. It has been, however, found in practice that the latter is by far the better plan, as the gradual decay of the soft rotting timber helps in a great measure to enrich the soil. Advantage should be taken, in clearing an estate, to saw up the trunks of suitable trees into scant-

ling and planking for building purposes, for the construction of bungalows, cattle-sheds, stores, &c. The top branches will come in handy for firewood. The more valuable kinds may be sold, as in these days of forest conservancy, there is a great demand for timber of all kinds, particularly satinwood, halmililla, &c. Every estate, if established on the site of a forest or jungle, should be able to supply material for its own fencing, as such material is not only costly but very necessary, and it is important that the fencing should be kept in good order from planting-time till the trees are tall enough not to require it.

As the trees will not come into bearing in from 7 to 10 years, advantage may be taken of the land to raise crops of Cassava and Indian Corn on it, the proceeds from which together with the results of the sale of good timber ought to recoup the proprietor for what he has expended on the purchase of the land. And here it may not be out of place to say something of Cassava and Indian Corn as subsidiary crops in cocount cultivation.

Indian Corn or Cassava may be raised just after the planting out of the cocounts, or half the land may be laid under Indian Corn, and half under Cassava. These will do no harm to the young palms, but on the contrary help to shade them from the sun in the earlier years of their growth: and as the seeds or slips of these products will be naturally put down at the commencement of the rains, they will not interfere with the process of watering of the palms which at this time will not require watering.

Indian Corn is put into small holes dibbled in the ground about 2 feet or less apart, 3 seeds being put into each hole in a triangular form. The seed sprouts earlier and more vigorously if soaked for 12 or 15 hours before planting. The seeds while waiting to be planted should be left on the cobs with their coverings on. Four or six of these cobs may be tied together by their coverings which are pulled over the cobs, and periodically, if not continually, exposed to the influence of smoke, which keeps them from being attacked by insects. Seeds treated in this manner may be kept for a year or even longer without injury by insects.

Cassava or Manioc is planted from slips, 3 or 4 inches in length, and placed in a slanting position, from 2 to 3 feet apart, in holes which are rapidly made by a chop from a mamotie. Neither Manioc nor Indian Corn require deep planting, and when the soil is not hard they are planted by the hand by the villagers. Manioc cuttings are kept for planting by tying about 50 of them into a bundle, and then placing them in a hole and watering for a few days, by which process they can be kept for a year or more if looked after. With other supports Cassava can be made to grow as a fence both graceful and ornamental.

The enemies of an Indian Corn-field are parrakeets which flock to it in thousands when the cobs begin to be formed, while villagers and coolies will also carry away as many cobs as their ingenuity can procure. These latter may also be put down as enemies of the Cassava plantation, while rats, porcupines and wild pigs have to be guarded against by the erection of strong and well-made fences.

When both Indian Corn and Cassava are fit for eating, the coolies or villagers working on the estate will readily accept either, in lieu of all or part of their pay. In the Eastern Province at least one need not be under any apprehension as to the sale of these crops. People will come a long distance and at great inconvenience to purchase the produce, and if the rainy season has been a favourable one, a very fair income may be expected.

But there is a question, in this connection, which is often asked, viz., does not the cultivation of Indian Corn and Cassava exhaust the soil? Very possibly so; but not to an appreciable extent. When these two subsidiary crops are raised on a new clearing, the soil is generally abnormally rich virgin soil: and as cocount trees need to be manured at a later period, the utilization and partial exhaustion of the land between the rows does not materially affect the palms.

I may here mention that to a planter, cooked Indian Corn or meal, and young cobs, are an excellent diet, while boiled manioc and milk, Cassava flour cakes, roasted manioc, and tapioca are by no means to be despised.

R. ATTERTON.

(To be continued.)

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

It was pointed out in a review of a past number of this Magazine, that the series of notes that I have been contributing under the above heading included a number of plants which might be erroneously supposed to produce food stuffs that could be adopted as a regular diet among the villagers. I should therefore mention that a great number of the plants which have been described, though not suitable to be used as substitutes for regular food, are yet edible, and that my aim in these papers is to describe such plants as are found in a cultivated state or growing wild, of which some part may be eaten.

Sapotaceae.

53. *Chrysophyllum Roxburghii*, G. Don.
Sin. Lâwnlu.

is a tree growing in the warmer parts of the Island. It grows to the height of from 30 to 60 feet, and is not very commonly met with. It bears a round fruit the size of an apple, with a green pericarp. The fleshy substance found in the fruit has a sweet taste, but is full of a gummy lacteous juice. The seeds are small and flat with a shining brownish testa. The fruit is eaten whenever obtainable, and is often brought to the markets for sale, where two to four of them are generally obtainable for a cent.

54. *Minusops Elengi*. Sin. Munamal.

This, too, like the above, is a tree growing in the jungles, especially in the warmer districts. The fruits are oval and small, about half an inch in length. Though green in the young stage they turn a brownish red. The mesocarp is pulpy when ripe, but contains a large percentage of caoutchouc-like juice. It is also astringent to a great degree,

When obtainable the fruit is eaten, especially by children, though it produces a peculiar astringency in the mouth.

The bark of this tree, on account of its astringent properties, is considered by native medical practitioners a good dentifrice, and is externally applied in cases of serpent bites.

55. *Mimusops Indica*. Sin. Palu.

The *M. Indica* is one of those trees which are found in the forests of the Island especially in the warmer dry districts of the South-East and the North-West. The tree grows to very large dimensions, and large quantities of a small oval fruit of the size and shape of a country date are produced. These when ripe are of a yellowish tinge, and contain a characteristic lacteous juice; nevertheless it tastes well and is consumed in the districts where it is obtained. The fruit of the *M. Indica* when preserved in syrup keeps well for a length of time. The timber of this tree is used for a variety of purposes, especially as planks for bridges, while it is also considered to be suitable for railway sleepers. The bark of this tree is used in native medical practice in preparing a gargle for sore throat. The fruits produce a sweet syrup and the seeds an oil.

W. A. D. S.

VETERINARY SCIENCE AT THE CONGRESS.

At the late Congress of Hygiene and Demography several papers were contributed on the various parasites, external and internal, transmissible from man to animals and *vice versa*. Dr. Klein endeavoured to demonstrate that various eruptions which he described as occurring on the udders of cows were liable to produce specific fevers in persons using the milk of these subjects. He also contends that he has produced experimentally diphtheria in the udders of cows by inoculating them on the shoulder with diphtheric discharges taken from the throats of children. Dr. Cruickshank, Professor McFadyean, Professor Walley, Dr. O. Ostertag of Stuttgart, and others expressed their incredulity as to Dr. Klein's conclusions regarding scarlet fever, which they had never seen in cows, and did not believe that it occurred in these animals; recent German experiments going to show that it is impossible experimentally to produce scarlet fever in cattle by inoculation.

Dr. Ostertag read a paper on the inspection of milk supplies. The milk from tuberculous and other diseased animals he would condemn, especially if the disease affected the udder. The ensuing discussion was carried on by various medical officers of health and veterinarians. There was a general consensus of opinion that dairies and milk shops should be registered and licensed; that milk sold to the public should be periodically examined by competent experts, and dairy cattle premises and persons employed in the business should be subject to veterinary and medical inspection. These provisions it was urged should be applicable to villages as well as city premises and business. It was believed that they might be, in a great measure, authorised and carried out under the powers of the Local Sanitary Authority, the Contagious Diseases (Animals) Act, and the Food and Drugs Act. But if these did not already authorise such supervision, they should forthwith be amended.

A whole day was devoted to a discussion on Tuberculosis opened by Professor Sanderson, who pronounced the disease distinctly infective and identical, as it appeared in man and in cattle. The milk from tuberculous cows was said to be more likely to develop tuberculous disease in persons using it than was the eating of the flesh of tuberculous animals. Professor Nocard thought that such food had special dangers for children. On the subject of tuberculosis, Professor McFadyean and Dr. Woodhead contributed a conjoint paper, in which they urged the abolition of private slaughter-houses and the institution of a general system of meat inspection, with a view to removing or diminishing the existing risks of dangerous diseases being contracted through the consumption of unsound or diseased animal food.

The Congress cannot fail to have effected much good in many ways, in stimulating the labours of those working in various departments, in recording the progress made against disease derivable from many causes, and in indicating the measures to be adopted for mitigating or removing the dangers that spring from these causes, and for securing the health of both men and animals.

The inspection of dairies, cattle and milk will no doubt form part of the duties of the Veterinary Inspectors in Ceylon, when such are appointed. It is a common complaint among householders that they cannot procure pure cow-milk, but these same householders are unfortunately very often no judges of pure milk, the general criterion of purity among them, being the "thickness" of the fluid. The lactometer which some use as a guide to ascertain the purity of milk, has now been decided to be no indicator of its nutritive value, unless it is known that the milk is unadulterated. Whether the milk be pure cow-milk, or whether buffaloes' milk be mixed with it is beyond the power of the lactometer to discover, but when different samples of unadulterated milk are to be tested, the instrument is useful to decide in what order they stand as regards nutritive value. It is a common practice to adulterate cows' milk with that from buffaloes as well as with coconut "milk," so as to "thicken" it, and deceive credulous householders. In cases where the milk is pure, but happens to be from a cow that has lately calved, objections have been raised against the milk which is thought to be diluted, but which under natural conditions contains a larger proportion of water than it does when drawn at a later stage. Again when pure milk is naturally of a very thick consistency, suspicion is aroused that it has been adulterated with buffalo-milk. The fact is that householders who purchase milk are content to have their milk of a standard consistency whatever components it may be composed of, and whatever its nutritive value. The average milkman at the same time becomes demoralized when he finds that he has opportunity for practising deception, and thus makes no attempt to secure a good milk yield by judicious management and feeding of his cattle.

The examination of milk and inspection of dairies—if these latter are not to be registered and licensed as recommended by the Veterinarians at the Congress of Hygiene and Demography,—if

insisted on by our local authorities will not only be a measure in the interests of public health, but also in the interests of agriculture, inasmuch as while such a measure will be a deterrent of milk adulteration, it will necessitate a more careful and rational system of feeding and generally managing milch cows with a view to the production of wholesome and nutritious milk, and indirectly raise up a better milking breed.

BY HIGHWAYS AND HEDGES.

Dr. Taylor, the popular writer of *Science Gossip*, has been lecturing on the Ingenuity, Sagacity, and Morality of Plants, and in speaking of the insectivorous plants, has referred to the Drosera or Sundew and the Nepenthes or Pitcher plant. Of the former there are three species in England, and no less than forty in Australia. There is more than one variety of Drosera in Ceylon, but the commonest would seem to be *D. Burmanni*. On the 43-acre block of land lately added to the School of Agriculture, there is a large plot right behind the school thickly covered with this species of Drosera which is not uncommon in the wet parts of the Cinnamon Gardens. In his lecture Dr. Taylor referred to the Pitcher plants of the Malay Archipelago, the pitchers of which he said were so large that sometimes they held half a gallon of water. He also mentions that small birds frequented these pitchers to drink, and after having imbibed the liquid within were prevented from getting out by two large pointed spikes, and were ultimately drowned. The Nepenthes of Ceylon (*N. distillatoria*) known as Bandoora-wel among the Sinhalese is a much smaller variety than the Malayan plants. The long tough stems are used by the natives for tying fences, and quite lately I was applied to by a medical man for a few of the fleshy underground stems, the juice of which he was anxious to experiment with on warts which are said to be removed by the application in a day or two. There is, not far from the School of Agriculture, a large patch of pitcher plants which have been freely drawn upon by guides and boys who sell flowers and foliage to strangers visiting our island.

When a minute fragment of meat is placed on the leaf of a Drosera, the tentacle-like glandular hairs of the plants bend over to grasp the intruding morsel, and a peculiar digestive fluid is formed as a result of the contact—just as the gastric juice in the human stomach is secreted when food enters that organ—and this fluid effects the solution of the meat, which is then absorbed. Substances, whether solids, gases, or liquids which contain nitrogen, only give rise to such results. The insectivorous or carnivorous plants, says Darwin, can even extract nitrogenous matter from pollen, seeds and bits of leaves.

Dr. Masters writing about these plants says: "The rationale of this mode of obtaining nutrition seems somewhat analogous to that in the root, where also the acid fluid with which the cell-wall is permeated, when it comes into contact with the particles of soil, determines their solution, and renders them fit for absorption into

the plants. Practically this admittedly exceptional mode of nutrition by the leaf might seem of little moment, but it is probable that in the future, direct nutrition by this means will be shown to be of much greater importance than it appears to be at present. In any case, the fact that ammonia-solutions and ammonia-vapour are absorbed by leaves with increased manifestations of vital activity renders this mode of feeding a matter of some consequence to the agriculturist; and the escape of ammoniacal vapour from the manure-heap may not after all be the wasteful operation it is usually supposed to be—that is, if the circumstances are such that plants can avail themselves of the exhaled vapour."

Melastoma (*M. Malabathricum*), a plant very common in cinnamon land, is known as Bowittaya or Katakuloowa among the natives. The fruit which is both astringent and sweet to the taste, dyes the mouth black, and this fact it is that has given to the plant the names of Melastoma (of Greek origin) and Katakuloowa, both signifying black-mouth.

Keena, or more correctly Guru-keena (*Calophyllum tomentosum*) is a tree belonging to the same family as the Domba (*C. inophyllum*), and like it contains a good deal of oil in the seeds. This oil is extracted and used in the Ratanapura district, among other parts, for burning. The tree is to be found in the neighbourhood of Colombo, and the timber is utilized for building, while the bark is used externally in native medicine to dispel swellings, and for dislocation and bruises.

Sera (said to be derived from the Malay word Sirih) which is so favorite a flavouring agent for curries, is the lemon-grass so largely cultivated in the Southern Province. It was at one time thought to be identical with citronella grass, and both were supposed to be cultivated forms of mana grass. The three are now distinguished under the respective names of Andropogon citratus, *A. nardus*, and *A. martini*. Both lemon-grass and citronella oils are exported from Ceylon, and are used by perfumers for scenting soaps and pomatums, the latter also entering largely in the composition of Eau-de-cologne.

Mana grass or patana grass is used as thatch for huts and as litter for cattle, while a new use has lately been found for it in the manufacture of tea boxes. Cattle eat the grass when it is young, but it is said that the milk, butter, and even the flesh of cattle consuming it acquire a peculiar flavour imparted to them by the grass. The occurrence of patanas was considered by the Rev. Mr. Abbay to be due to the outcrop of a quartzite rock-formation, the disintegration of which results in a soil which is too poor to support a forest growth. This theory is however by no means generally accepted.

In the *Household Register* of September 18th is given the experience of a lady, of the tendency of a twining plant to turn towards a support placed near it. The support or pole, we are told was on the side away from the light, and the phenomenon of the plant turning towards it is said to have been difficult to account for

except by supposing that the plant could see the pole. In one of our previous issues we referred to the peculiarities in certain plants which would easily explain this phenomenon. The property of negative heliotropism, i.e., the bending of growing organs away from the source of light is exhibited in such plants as the ivy and vine, and as we have before explained, is due to the more active growth of the more powerfully illuminated part. It is this property that would explain the tendency of the special plant referred to by the lady to turn in the direction of a support which was away from the light. The growing part of twining plants is very sensitive—the slightest touch against any object making it bend towards the object for support. Professor McAlpine used to describe the effect of such contact as a "tickling" process to which was due the curling of the tips of the growing part—the contraction at the end being conveyed backwards and the whole plant drawn and tightly fixed. It is after the support is touched and adhered to, that the tougher tissue is developed and the position of the plant strengthened. Without a support within reach the growing part of a twining plant may keep moving about (away from the light if it be negatively heliotropic) till it touches a support to which it then inclines to adhere. This tendency of plants to twine round a support is caused by the more rapid growth of the right and left sides of a growing organ in succession, and is known as revolving nutation. It would thus appear that it is altogether too much to assume that plants are endowed with the sense of sight!

ROVER.

THE STORING OF SEED GRAIN.

The selection and storing of seed grain are matters of the greatest importance in agriculture. It is much to be regretted that from some cause or other the careful selection of seed,—the advantages of which are fully understood by our cultivators,—is not at present practised even to the extent it was at one time. The preservation of seed intended for sowing is another subject upon which any advice must be very welcome, as it often occurs that the seed which is expected to raise the future crop is at the eleventh hour found to have become musty or to have been attacked by some kind of insect, so that its germinating power has been completely destroyed.

The Agricultural Department of Madras in its Bulletin No. 10 takes up the consideration of this subject, and details the methods of preserving seed grain in vogue in some of the districts of the Presidency. The hints embodied therein must from the similarity of conditions under which cultivation is carried on in India and Ceylon, as well as from the simplicity of the means which are enumerated, be of value to the cultivators of grain in this Island.

Four methods of storing the seed are noted, viz., in baskets; gunny bags; earthen pots and straw bundles.

The baskets for storing grain are made of split bamboos, of a circular or rectangular shape and of various sizes. To fill up the spaces between the bamboos they are coated inside and out with

cowdung. The baskets are generally used when large quantities of grain have to be stored. When the grain is placed in this kind of receptacle it is covered with a layer of straw and the mouth plugged with a thick layer of cowdung and earth.

The gunny bags are used when smaller quantities of grain are to be stored. The bags are simply kept loosely in some part of the house, where there is constant movement, so that the bags are frequently trampled on, shifted or used as seats by the inmates.

The earthen pots which are used are made in the shape of two inverted cones either of earth mixed with paddy husks or calcined earthenware, and are always kept whitewashed. When stored in pots sometimes the grain is liable to be damaged by insects. The best plan is that of storing the grain in straw bundles. For making the bundles a quantity of paddy straw, all of uniform length, is tied together at the butt end, and then placed in a basket and evenly spread out so as to make a hollow in the centre. On this a small quantity of loose straw is spread and the grain is put in. The outer straw is then gathered together at the top, and the whole bundle is bound round and round by a straw rope and finally secured by an ordinary rope. This form of storing is used in case of large grains, and the bundles are not opened till the seed is required for sowing.

In storing seed grain various substances are placed in the vessels to prevent insect attacks. Among these are mentioned the leaves of Margosa, the pods of Bengal gram, varagu (*Paspalum Scrobiculatum*) and wood ashes respectively. In Ceylon the villagers usually put in a lot of lime leaves and chillies along with grain to prevent insect attacks.

It is always of importance to dry the seed perfectly before storing away, for the least trace of moisture is apt to injure their germinating powers.

The line grains such as Cumbo (*Pennisetum Typhoides*), Kurakkai (*Eleusine Coracana*) and the Panicums are usually better preserved when the whole ears are stored without threshing, the last operation being done just before sowing.

W. A. D. S.

CEREMONIES OBSERVED BY THE KANDYANS IN PADDY CULTIVATION.

Paddy is liable to be attacked by a grub known among the Kandyans as *kok-panuwa*, which sucks the juices of the plant. To avert such attack a *kema* or charm called *pas-pulutu-kema* is arranged for by the Kapurala. Five kinds of grain seeds are fried in a pan and afterwards spread on some mud which is moulded over a coconut shell. About dusk (*gomman vena velava*) the Kapurala after going through a process of purification, proceeds to the infested field with this preparation, carrying a lighted torch in his hand. The *kema* is placed on a piece of wood, and the lighted torch is allowed to burn till the fire is extinguished. After this the Kapurala returns home, but not by the same road he went to the field, and to nobody must he utter a word on the way. Another method of dealing with this pest is to submerge the crop with water

for a time. In some parts of the Kurunegala district an oleaginous mixture with a pleasant scent is smeared over arcanut flowers by the Kapurala, after reciting the *Ithipiso Gatha*, and suspended on sticks in different parts of the field. In the Anuradhapura district, sand, after being "charmed," is scattered over the field, and offerings are made to *Jyana Dewiyo* with a view to inducing his intercession to stay the ravages of the pests. Mr. Bell, of the Ceylon Civil Service, in writing about the cultivation of hill paddy, describes another kema called *nava nilla*, practised by the cultivators of the Sabaragamuwa district.

When the paddy is approaching maturity other ceremonies are gone through, the goiya, after purification, places three ears of grain on a leaf of the Bo-tree, which is held in great veneration for reasons too well known to need mention, and buries them in the kalawita or threshing floor, at the same time chanting some mystic words, invoking the gods to protect the crop from flood, fire, birds and wild beasts. A day or so prior to the harvesting a few women are set to smear the threshing floor with cowdung. The crop must not be taken in on days on which *poya* (the sabbath of the Buddhists), *Sangrahanti* (when the changes in the moon occur) and *Vitti* (inauspicious days) fall. Again the neketrala, attired in fantastic dress, describes a peculiarly-shaped figure with ashes which he carries in a winnow, with a view to preventing *huniyam* (sorcery) and other evil influences. This ceremony is known as *ahucanwadanawa*. Another rite of a peculiar nature follows this, known as *arekwalé-tiyawawa*. It consists of digging a circular hole in the field and placing inside a model of the sacred footprint of Buddha (Sripade,) a husked coconut, a creeping plant, clusters of arcanuts, leaves from the heeraspali (*Vitis quadrangularis*) and Tolabo (*Cinnam asiaticum*), and covering these with about three bundles of straw. The figures of the *poora lella* (leveller), laba (measure), sun and moon are also described with ashes in the kalawita. The village astrologer is of course resorted to in order to ascertain a lucky day to reap the field. On such a day a number of men with their eyes directed towards Adam's Peak, and assuming a joyful mood, proceed to the field with their sickles, and verses are sung in tara by the reapers. Another ceremony which precedes threshing consists in three nursing mothers clad in white, having to go round the field seven times carrying paddy on their heads, and then suddenly coming to a standstill and retreating, without uttering a word, to the three corners of the kalawita. Then after giving utterance to some incantation, they drop their burdens on the ground, and this is the sign for threshing to begin.

T. B. POHATHI KEMELPANALA.

GENERAL ITEMS.

We quote the following from the interesting report of the School of Industry, Happy Valley, Haputale:—"Our chief industry, however, is Agriculture. This is in accordance with our original plan, with the object of the Government grant, and with the requirements of our Agricultural

Colony. In this respect we are following the examples of the best Industrial and Reformatory Schools in England, where farming is regarded as providing not only an appropriate industry in such schools, but as a source of supply for good farm labour, and as having a good moral effect on the boys. Many of the boys are also being trained in theoretical agriculture by the Agricultural Instructor, thus supplying, together with the ordinary work, an important branch of technical education for the more intelligent lads. It may be interesting to note in this connection that this is a feature of the English Technical Instruction Act of 1889. Mr. Ritchie in reply to a question put by Mr. Gathorne Hardy in the House of Commons in February last, stated 'that technical education was intended to include not only technical but manual instruction, and the latter comprised instruction in processes of Agriculture.' Some of our agricultural experiments have not been successful. We have been disappointed at the results of our cotton cultivation. But we have been fully compensated for that in the returns which we have realized from the planting of manioc, the roots being readily bought by the villagers in the neighbourhood who have developed a great liking for it, and will probably plant it themselves. We have also succeeded in making small quantities of tapioca from it, and hope before another report is issued to have the means of preparing it on a larger scale. The growth of English vegetables has already been mentioned as a productive branch of our enterprise, though we must wait for the railway which is to come through the property, before we can obtain any considerable sale, when we hope to contribute our share to the supply of the Colombo markets. Nor have the so-called native vegetables been neglected. Brinjals, chouchous, sweet potatoes, chilies, &c., sufficient, not only to supply the boys with carries, but to sell to the villagers, have been grown in the gardens. We have to express our thanks to Messrs. Sutton & Son for a good supply of seeds given us free of cost. It is a part of our programme that every boy in the Valley, no matter what his special industry may be, should be taught gardening."

It has been suggested by the *Ceylon Observer* that the breeding of horses in Delft Island should be revived. Horses used to be bred in Delft for supplying animals for the mounted orderlies. Their systematic breeding was, however, discontinued some thirty years ago, and it is now proposed that some fresh blood should be infused into the present breed, which has deteriorated from in-and-in breeding, with a view to producing animals of a better type that might be available for a tramway company. Delft is well-known for the good pasturage it supplies to cattle, and the suggestion that the breeding operations should be revived, under intelligent supervision, is one worthy of serious consideration.

The new fibre plant which was announced as discovered on the shores of the Caspian, and known there as kanaff turns out to be none other than *Hibiscus Cannabinus*, of which a small plot was raised at the school some months ago. It is also known as Deccan or Amba

hemp, and is cultivated in India for its fibre which is soft, white, and silky, capable of being bleached or dyed in every shade and colour, and suitable for the same purposes to which jute is applied. Dr. Watts says of it, were a demand to be created for this fibre as distinct from that of sun hemp (the Siuhalese *Hana*) or other fibres, the cultivation of the plant might be indefinitely extended, and with profit to many needy cultivators who are unable to produce either jute or cotton. When it is considered, says the *Board of Trade Journal*, that Russia annually consumes more than 150,000,000 of sacks, a third of which is imported, it may easily be seen that the appearance of a new textile on the Russian market is an event of no slight importance. The leaves of *Hibiscus Camabinus* are said to be used as a pot herb and eaten like spinach, while the seeds are sometimes exported from India to England as an oil seed.

M. Raoul, a French Colonist of Tuhiti, is reported to have succeeded in growing a hybrid obtained by crossing the Sea Island cotton, which produces a beautiful silky fibre that is however difficult to manipulate, and a wild cotton shrub of Guadaloupe. The richness of the yield and the quality of the fibre are highly spoken of.

Mr. Tiathonis, Agricultural Instructor, writes:—Wellanduru is a small village situated on the mail-coach road to Rakwana, and 6 miles distant from Pelmadulla. It consists of about 50 dwellings, a small number of boutiques, and a Government boys' school. The climate is fairly healthy, and is influenced no doubt by the situation. There is a very useful rivulet which flows by the road which the inhabitants have unfortunately allowed to become very filthy, neglectful of sanitary requirements. The villagers chiefly carry on the cultivation of paddy, arec-nuts, and chena grains. The paddy-fields are fairly fertile owing to the wash from the neighbouring hills, but cultivation is irregular as much from the poverty as the indolence of the inhabitants. The four seasons for paddy are known as pera-maha, maha, pera-yala, and yala. The Experimental Garden has been, after some difficulty in clearing and preparing the ground, extended to nearly 2 acres, and is partly occupied with betel, English and Native vegetables, and mustard, the rest to be devoted to cotton and tobacco.

It has been suggested that investigations should be made with a view to ascertaining the extent to which the bark of trees can be used as cattle food after being milled. Besides the saving that the use of barks as cattle food will effect, it is contended that when intelligently used, they will preserve the health of stock, and prove preventatives against infectious and contagious diseases.

A writer on the subject of village sanitation in the *Indian Agriculturist*, offers some practical suggestions for the improvement of the sanitation of villages. He suggests that a committee should be constituted, called the Sanitary Committee, for each village, consisting of several members, and placed under the direct control of an executive officer. That every village which possesses several tanks or natural reservoirs should reserve one or two strictly and exclusively for drinking purposes, and that where these are absent, deep wells should be dug in sufficient number to supply the village with a copious supply of fresh water. To free the atmosphere from miasma, the stagnant pools in the vicinity of each house should at least be cleared of the overhanging verdure that works the double mischief of intercepting light and air from above, and by dropping down leaves fills the water below with vegetable matter that in decomposing pollutes the water and the air.

The yearly record of butter production, says the *Breeders' Gazette*, has been everlastingly smashed by the Holstein Friesian cow, Pauline Paul, which has just completed a 365 days test, which yielded a total of 1,153 lbs. 15 $\frac{3}{4}$ oz. of marketable butter salted 1 oz. to the lb. This exceeds the highest previous yearly record by 208 lbs. 6 $\frac{3}{4}$ oz., the excess itself being above the estimated yearly yield of our common dairy cows.

A large body of water has been discovered at El Golea, in the Sahara Desert, about 120 ft. below the surface. It throws up nearly forty gallons per minute at present, and it is anticipated that the yield will be much greater when more perfect access to the water is attained. The discovery is regarded as of high importance, as this is the first time that water has been found in the Sahara at such a slight depth under ground.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, DECEMBER 1ST, 1891.

[No. 6.]

THE INDIARUBBER SYNDICATE.

FEW months back there was started a project, upon which we commented at the time, to form a syndicate to obtain complete control of the indiarubber trade both in America and Europe. This

attempt has now come to grief, and whether it would have benefited or have injured such cultivation of the rubber trees as has already been attempted in this colony, its possible results may now be wholly and entirely disregarded by planters interested in the enterprise, few in number now, we suspect. We deem it to have been extremely questionable if, even had the scheme been found to be practicable, it could have done anything to stimulate increased production in Ceylon, and we cannot say that we are sorry that another of these gigantic monopolists which have been so injurious to regular trade all the world over should have turned out a failure.

The syndicate in question was originally organised with a capital of 10 million dollars, of which 1 million dollars was at once subscribed, and another $1\frac{1}{2}$ million dollars was obtained from other sources. We now learn that this whole amount has been lost, the English banks having suffered to the extent of about 1 million dollars. In Brazil the operations of the syndicate so stimulated production, collection rather, that it would have required more than double the capital possessed by the syndicate to hold the stocks which it had obtained and to secure the rubber due to arrive on their hands. The banks began to be alarmed at the prospect and refused further advances, and when the sale of the accumulated stocks became compulsory, prices tumbled down to an extraordinary degree, fine Para rubber falling from 80 cents to 63 cents per pound. Messrs. Baring Brothers are said to have been holders of no less than 500 tons of the rubber, and altogether the syndicate hold 3,600 tons of it, nearly the whole of which cost 80 cents and more per pound laid down in New York and London. The selling prices having fallen, as we have stated above to 63 cents, it is no wonder that collapse followed, and that we are likely to hear little

more of attempts to "corner" the trade in indiarubber. It is therefore undoubtedly lucky for those who have yet continued the cultivation of the trees upon estates in Ceylon that the whole scheme has collapsed before the operation of the syndicate reached the island. It is extremely questionable if the syndicate would have offered prices such as would have induced our planters to have gone in for extended cultivation, but the planters might have done so if they shared in the hopeful anticipations of the syndicate. As it is, the bubble has burst before there had been time for Ceylon planters to outlay more money on this form of cultivation; but if any have collected and exported the gum, they have had, at least, to pay a certain penalty in the heavy reduction in the London market of the prices formerly obtained for their production of the article. We suspect that this failure will have a beneficial effect in doing away, with this mischievous system of "cornering" produce, as to which we have always written our view that it was both immoral as well as commercially unsound. Our condemnation in the last sense has been constantly proved correct; for any attempt made in that direction since people became alive to the operation and its sequence has come to grief. The practice is a sort of trade unionism without any of the redeeming features of the latter. This has a few philanthropic motives—at all events professed—to justify it, while these syndicates are nothing more nor less than attempts to convey the money of the many into the pockets of the few. Little sympathy we feel, need be wasted over those whose imaginary gains have been converted into real loss over this rubber speculation.

THE PROFITS OF JAVA CINCHONA PLANTERS.—A few years ago a lengthy article (from which we quoted at the time) appeared in a Dutch-Indian technical journal giving details concerning the cost of production of cinchona bark in Java. In the Preanger district, where the largest and the best-managed estates are situated, the wages of labourers in the plantations average 8d to 3 $\frac{1}{2}$ d per day for men, and about 2 $\frac{1}{2}$ d per day for women and children. From these and other data figures were deduced which show that at a sale unit of 6.7c in Amsterdam ($1\frac{1}{2}$ per lb.) a well-managed estate of seven-year-old trees, yielding an average of $4\frac{1}{2}$ per cent bark, would yield an annual interest of 10 per cent on the capital invested. Eight-year-old trees of the same alkaloidal richness will pay 10 per cent even at a unit of 5.2c (equal to 15.16ths d. per lb.); and nine-year-old trees yielding 5 per cent quinine sulphate, will pay 10 per cent profit at a bark unit of 4.3 (equal to $\frac{1}{2}$ d per lb.)—*Chemist and Druggist*,

ABBOTSLEIGH TEA ESTATE CO., LIMITED.

LONDON, Oct. 9th.

Another of the private companies which have of late years so multiplied for the working of tea estates in Ceylon has been registered this week. The following extract from a financial paper will give you all particulars respecting it. I am told that there will be no appeal made to the public for subscription to its capital:—

This company was registered on the 29 ult., with a capital of £25 000, in £100 shares, to acquire the Montefiore Tea Estate in the Central Provinces of the Island of Ceylon, and also the Abbotsleigh Estate in the same province, and to carry on the business of growers of tea, coffee, cinchona etc. The subscribers are:—

C. B. Smith, 7, Grove End Road, N. W. tea estate owner	1
N. Rowsell, Abbotsleigh, Hatton, Ceylon, tea planter	1
C. Harrison, 67, Lincoln's Inn Fields, W. C. solicitor	1
H. W. Matthews, 9, Coleford Road, Waudsworth, S. W. clerk	1
F. Villier, 24, Kitt's Road, St. Catherine's Park, S. E.	1
F. Farris, 49, Morley Avenue, Wnod Green, N., clerk	1
G. Anderson, 12, Brookville Road, S. W. clerk	1

The number of directors is not to be less than 3, nor more than five; the first being Messrs. C. B. Smith, W. W. Simpson, N. Rowsell, and C. Harrison; qualification, three shares; Mr. C. B. Smith is managing director in England, with a remuneration of £100 per annum; Mr. N. Rowsell is the managing director in Ceylon, with a remuneration of Rs. 000 per annum and 5 per cent. on the nett profits. Office, 41, Eastcheap E. C.—London Cor.

BARK AND DRUG REPORT.

(From the Chemist and Druggist.)

LONDON, Sept. 26th.

CINCHONA.—The auctions held on Tuesday were again exceptionally small, the total number of packages being made up as follows:—

	Pkgs.	Pkgs.	
Ceylon cinchona	157	of which 124 were sold	
East Indian cinchona	393	do	357 do
Java cinchona	78	do	78 do
South American cinchona	273	do	219 do
Total	900	do	778 do

The assortment was rather above the average of that of the recent auctions, and the better parcels were competed for with somewhat more animation than the buyers have been accustomed to show of late. The general opinion is that the auctions showed some improvement on those immediately preceding, though there is no quotable advance. The average unit for barks of fair quality remains stationary at 1½ per lb.

The following are the approximate quantities purchased by the principal buyers:—

Agents for the Mannheim and Amsterdam works	61,187
Messrs. Howards & Sons	39,665
Agents for the American and Italian works	23,320
Agents for the Frankfurt a/M. and Stuttgart works	20,000
Agents for the Brunswick works	6,633
Agents for the Auerbach works	3,810
Agents for the French works	3,210
Sundry druggists	20,066

Total quantity of bark sold	178,511
Bought in or withdrawn	29,313

Total quantity offered

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quality represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots and vice versa.

The following figures represent the exports of cinchona bark from Java during the month of July (the opening month of the season) of the last five years:—

	1891	1890	1889	1888	1887
Government Plantations, Amsterdam lb.	60,000	12,487	34,827	11,021	76,090
Private plantations, Amsterdam lb.	1,103,173	373,025	20,510	162,980	218,78
Total	1,164,163	385,512	305,337	174,001	206,486

It will be seen that the exports for the month of July 1891 alone exceed those of the four preceding months of July combined.

THE AMSTERDAM CINCHONA AUCTIONS.

(Telegram from our Correspondent.)

AMSTERDAM, Thursday Evening.

At to-day's bark auctions the very large quantity of nearly 6,200 packages Java bark was offered. Of this quantity 4,937 packages sold at firm prices, though no advance can be reported, the average unit being 6 cents. per half kilo., or 1 1/16d. per lb. Manufacturing barks in quill, broken quill and chips brought from 6 to 47 cents. (=1d. to 8½d. per lb.), ditto root, from 8 to 45 cents. (=1½d. to 8d. per lb.) For druggists' barks in quills broken quills and chips up to 50 cents. (=9d. per lb.) was paid, and for ditto root from 11 to 14 cents. (=23. to 23½. per lb.) The principal buyers were the Auerbach, Amsterdam, and Brunswick works.—*Chemist and Druggist*, Oct. 10th.

Correspondence.

To the Editor.

TEE-TOTUM VERSICLES.

DEAR SIR,—Could you find space in your valuable column for the following lines, not on account of their intrinsic merit, but for the soundness of their sentiment. PLANTER PETER.

IN PRAISE OF CEYLON TEA.

(With apologies to "Gipsy John.")

Another day is over,
From care and toil we're free;
New should the soog-famed rover
Come punctual home to tea.
Why should he with such constant mind
Have all things else foregone?
The reason is not hard to find,
His tea came from Ceylon.

(Chorus) They put hot water in the pot,
And pour it out with glee;
You'll swear mere earthly drink cannot
Compare with Ceylon Tea.

The gods who in Olympus
Ambrosial nectar quaffed,
Though Vulcan with a limp pass
To fill their cups, they laughed;
Think would they have themselves disgraced
In such a fashion,
Had their poor nectar been replaced
By Tea made in Ceylon?

(Chorus) Then put hot water in the pot,
And pour it out with glee;
You'll swear mere earthly drink cannot
Compare with Ceylon Tea.

Lovers of sparkling wine there be
The reverse of ascetic,
With whom champagne does not agree
(It's dear as an emetic?)
Then why not be more rich in purse,
Though you wear no blue ribbon,
Drink that which ne'er made body worse,
The Tea of Old Ceylon.

(Chorus) Then put hot water in the pot,
And pour it out with glee;
You'll swear mere earthly drink cannot
Compare with Ceylon Tea.

Now mind the water's boiling;
The servant, if it's not,
Should by a just recoiling
Find himself in some ash hot.
Put tea, when the right heat is struck,
A spoon for each person,
With an extra one which is for luck
To the Planters of Ceylon.

(Chorus) Then put hot water in the pot,
And pour it out with glee;
You'll swear mere earthly drink cannot
Compare with Lanka's Tea.

NOTES ON PRODUCE AND FINANCE.

THEN AND NOW.—A few years ago it was quite a difficult matter to procure pure Indian tea from the retailer. In issues of this paper, published in 1881 and 1882, we frequently called attention to the prejudice shown by grocers to tea of Indian growth, and the difficulty experienced in purchasing it without an admixture of China tea. All this is now altered. The grocer now takes a very different view of the matter and their trade organs no longer give a "friendly lead" to the Chinese leaf. In an article on tea, which appeared in the *Northern Counties Grocer's Review*, we find the following:—"The introduction of Indian tea into England was gradual, but retailers, having once commenced to use it in their blends, very soon began to increase the proportion, it giving a superior flavour to the China product. No stronger proof can be adduced of the hold which Indian tea has obtained in Great Britain than the increasing percentage of the total amount of tea consumed. Its progress may have been slow, but it has been sure; no taint of adulteration has ever sullied the reputation of British-grown tea; its purity has been above suspicion, and its character unimpeachable. The substitution of machinery for the performance of many of those functions which in China are carried on by the hands of the natives greatly reduces the probability of contamination, and tends to preserve the aromatic properties natural to the leaf." Of Ceylon tea the same article says:—"The development of the tea industry in Ceylon is of such comparatively recent date that the history of the enterprise is of very great interest, showing, as it does, that the pluck and endurance of the colonists, after having passed through some most disastrous financial difficulties, is likely to lead to one of the greatest industries of our Eastern possessions. The bulk in fact nearly the whole of the exports of Ceylon tea, have been consigned to England, but the annual statistical returns show that the Continent and America, and nearly every tea-drinking country have found out the value of Ceylon tea, and appreciate the same, including Russia, which has during the past season taken a considerable quantity of the finest favoured teas."

LAST WEEK'S TEA MARKET.—Discussing last week's tea market, the *Grocer* says:—"Home trade is most depressing, and export is worse. The famine in Russia is so bad, that there is no likelihood of their being able to take Monings in any quantity from here, and the fate of all the fine Ningchows left looks sad. Our market does not want them over 1s. per lb., and that only in limited quantity, but we believe at 7d. to 10d. (the price at which medium to fine Ningchows are now selling, the trade must find they are of use to them. Teas now offer splendid value, but dealers are most unwilling buyers. The feeling is "panic," but we cannot believe it will go on, as present rates must have the effect of stopping very considerably the export from China; this idea is reflected in the clearing-house by hardening quotations for the spring months. The heavy supply and low quotations of common Indians is also very bad for the market—they are so poor that they are not wanted by trade—low-priced Chinas offer them better value, and are more useful in blending. What the trade want (in quantity) is good Indian tea about 8d. to 10d. per lb., not sixpenny bathy hot water. The quantity of Ceylon is falling off, and quality is improving, so that prices and the position get stronger each week. Finest grades Ceylon tea have been in strong demand, and mark an advance of 1d to 2d. Estates such as Portwood, Goatfell, Invery, and Chapeton maintain a standard of high quality, and realise proportionate rates. Nearly 15,000 packages were offered. Commonest kinds still move at low rates. The market closes with a healthy tone. The statistics of this article for September, just completed, show that the imports into London were 4,713,200lb., against 3,244,800lb. in 1890; and notwithstanding that the deliveries for the month were

heavy, viz., 5,277,400lb., instead of only 3,960,450lb. in the previous year, the stock of 16,582,300lb. on the 1st inst. exhibited a considerable excess—viz. one of not less than 6,701,900lb. The total landing, of tea of all kinds at this port during September have reached 28,452,150lb. as compared with 22,342,390 lb. in 1890; so that as the joint deliveries have not exceeded 20,437,200lb. against 21,514,650lb. in the same month last year, the general stock has been largely augmented, and now present a relative surplus of 8,860,700lb.

THE RECENT SPECULATION IN COFFEE.—The recent disturbance in the coffee markets of Havre, Hamburg, and Antwerp is due, says the *Financial News*, to the operations of a clique who have tried to "corner" coffee. In July last the brilliant idea was conceived of cornering coffee in Europe, in face of the largest coffee crop ever marketed in Brazil. The rig was palpable, and had a certain amount of success because of the disinclination of merchants to sell "September" owing to the small stocks in Europe and the generally strong statistical position at the time of the article. Then the October position was taken in hand, and prices of this delivery were also advanced by leaps and bounds, until at last merchants felt that the clique had over-stepped the mark, and offered freely coffee for shipment from Brazil at lower and lower prices, until the rig utterly collapsed and left the clique with a large stock of high-priced coffee.

THE BOARD OF TRADE RETURNS AND PRODUCE.—The Board of Trade Returns for the past month are again unsatisfactory, especially as regards the exports, but it must be remembered that in September, 1890, the exports were swollen by extra shipments to the United States. The imports are valued at £31,189,000, a decrease of £1,362,000, or about 3½ per cent.; and the exports at £20,793,000, a decrease of £1,971,000, or about 8½ per cent. The import of tea for the month is 27,078,753 lb., representing in value by £1,201,469 as against 22,496,729 in Sept. last year, representing in value 1,021,661. Coffee 43,533 cwt., against 32,738 in the corresponding period last year. The increased receipts of tea are mainly caused by the Chinese shipments being much heavier. At the same time there is a decreased consumption of China tea, Ceylon sorts being in demand. The cane-producing countries have contributed to swell the total of raw sugar; for instance, the receipts from Java, which in September, 1890, were *nil*, last month were 189,481 cwt., and from the Philippine Islands and the British East Indies the landings were 153,403 cwt. and 139,520 cwt. respectively, against 38,700 cwt. and 78,903 cwt. The sources of our supply of wheat have changed considerably since last year. For example, Russia, which sent us 1,893,287 cwt. in September, 1890, has only shipped 620,503 cwt.; the Roumanian supply has dropped from 1,627,183 cwt. to 110,652 cwt., and the Australasian from 391,476 cwt. to 278,107 cwt. On the other hand, the United States sent us nearly twice as much as last year, the quantity being 2,791,602 cwt. compared with 1,416,927 cwt., and in addition 1,014,007 cwt. of wheat flour were received thence, compared with 887,587 cwt. Chili, the British East Indies, and Canada also appear to have surpluses of wheat, as the shipments in each case were larger.—*H. and C. Mail*, Oct. 9th.

THE RETAIL PROFIT ON TEA.

The interest of the tea planter in the product he cultivates is not confined to the price it realises in Mincing Lane, but extends to the retailing of tea as well as the retailer and his profits. Two trade journals, whose province it is to guard and protect the grocer from the harm that besets him in this sinful world had something to say last week on the subject of tea and the profit made on it by the retailer.

TEA PURFERS AND THE GROCERS.

Taking the above for its theme, the *Produce Markets' Review* says:—"In not very remote times there was a certain respectability attached to the tea trade, but it has now evidently fallen on evil days. Even a

knowledge of the business seems to be superfluous when a passport to success is, that the vendor is well known as a purveyor of something else, and so much is this the case, that sellers of tea boast upon every wall and boarding that they are not grocers. In one instance, we believe that the public have been assured that, after paying immense advertising expenses, the regular trade can be undersold to the extent of 1s per lb., without including free postage. Now, 1s per lb. on a consumption of 200,000,000 lb. of tea a year represents arithmetically £10,000,000 sterling—an extent of benevolence which the public can hardly expect, either as the voluntary surrender of profit, or as the gift of the richest company. Further, as good tea is habitually sold by grocers at 1s 6d per lb., and to undersell this by 1s, would mean a retail price of 6d, out of which (allowing nothing for the cost of the tea) the duty would come to 4d, while packing, advertising, and free postage would cost another 4d per lb. In fact, it does not require any acknowledgment of the tea trade to assert that few more fallacious statements could be made than that the grocers overcharge the public 1s per lb. for their tea. Another strain on public credulity is the assertion that tea in leaden packets, which, with advertising, must add 3d per lb. to the cost, can possibly be cheaper or better, than tea offered fresh from the chest, without this added cost and risk of deterioration. If all the tea marked Ceylon comes from the island, the tea trade is also more ignorant than its tradenoers make it out to be. Nor should a triumphant success in the retailing of butter or pork be much of a passport to the favour of the tea-drinker. An older advertising development, which has rather sunk into the background of late, is the so-called "present" system. Under this the trader gives a trip to the seaside, a grand piano, or what not, to the buyer of so many lbs. of tea. If all these gifts come out of the superfluous profits hitherto enjoyed by the grocers, the strange thing is that the latter are not millionaires, instead of being, as many of them are, men struggling for subsistence. All these matters, however, concern the public, and, although the power of self-assertion is no doubt unlimited, our thirty odd million of people will, no doubt, draw the line somewhere. The consumer, sooner or later, will realise that the division of labour, on which all modern society rests, applies to tea as well as to everything else. For a man to attempt to grow the tea he sells by retail, is to ensure its being as dear as our boots or hats would be if we made them ourselves, in order to save intermediate profits.

A new development in advertising, to which we wish to draw the attention of the trade, is that those who are endeavouring to deprive them of their living are now audacious enough to offer to supply them with tea. In fact, the despoiler now kindly offers to put the grocer on his feet again by offering him tea cheaper than it can be bought in a market noted for the intensity of its competition and for the immense capital embarked in the wholesale trade—of late years, at any rate—for less than a living profit. The grocers have shown a good deal of the quietude of doves under the torrent of mendacity that has been poured upon their tea trade, but they have a reserve of the wisdom of the serpent left about them. The endeavour to destroy one's trade is surely a strange preface to an offer to supply you with goods, yet this is what is being done in the most open way. Some firms are endeavouring to regenerate society by under-selling the grocers, by whom they live. This may be philanthropy, but it is certainly of a one-sided character. Others, with dozens, or a hundred or more, of competing retail shops, are now appealing to the grocers for support, but in most cases under a different name from that in which their shops are carried on. Then, again, packet tea advertisers—whose attack upon the grocers' trade and profits is the most insidious of all—actually offer to make them agents, to aid in their own destruction, and the astounding feature in the case is, that grocers are to be found ready to play into their hands. Further, so-called wholesale houses open shops, with various high-sounding names, all over a town, and, at the same time, by enticing statements and advertisements, endeavour to persuade

the grocers to buy of them. In a similar way, in the wholesale trade, the merchants and brokers endeavour to supplant those by whom they live. In short, the tea trade at present consists in coveting and desiring other men's business, and in expecting the victims to assist in their own happy despatch.

It is surely time that the grocers set to work to turn the tables on their antagonists. Let them carry the war into the enemy's country, expose the mendacious statements that are made, and offer cheaper and better tea, as they can very well do. There is no doubt that the grocers, as general distributors, not dependent on any one branch of their trade, can offer tea more cheaply than any other retailers, especially as they understand the trade, and have a knowledge of the commodity they sell. They have, perhaps, relied too much on the public knowing their position, and have let their adversaries obtain a foothold. If, on the contrary, the grocers once made up their minds to "cut" in tea, no one else could live with them. Such an extreme step is probably by no means necessary at present, as the competition is only serious when it is left alone. But it is clearly time for the tea trade to set to work to expose the delusive statements by which it is sought to mislead the public.

THE RETAIL PROFIT ON TEA.

The Grocer, discussing the subject, says:—This subject is one which engages the careful attention of our readers, many of whom look back with feelings of regret to the time when a profit of one shilling per pound was not thought unreasonable upon the higher-priced canister, and when the margin on even the lower or more popular-priced tea was sufficient to cover a loss on the sale of sugar and still leave a fair profit for the retailer. Those days have, however, passed away. With the reduction in the duty and by keener competition the retail prices have been brought down to a very low figure, and as the grocer has educated the public to pay prices ranging from one shilling to two shillings per pound, it is not likely that the retail price will reach any higher figure, unless war or some other cause should at a future time lead to an increase in the duty. But, as public opinion seems to be in favour of the abolition of the duty altogether, it is not probable that any Chancellor of the Exchequer would attempt to raise money by increasing the duty on tea unless there were some pressing necessity. As regards the price of tea in bond, the falling-off in the supply from one part of the globe seems to be more than compensated by the importation from another, as evidenced by the decline in China tea being amply compensated by the rapid strides made by the island of Ceylon, so that there is little fear of there being any substantial increase in the price of this article.

Under these circumstances it may be assumed that there is no probability of a material change in the cost of tea to the grocer, and there should be no further reduction in the selling price to the public, who can now buy tea of fair quality at about one penny per ounce. Indeed, any further reduction in the retail price must involve a diminution in profit, which the trade can ill afford to bear at the present time. In our opinion the success of a grocer's tea business depends in a large measure on the quality of the article sold, and its suitability for the water of the district in which it is made. We believe the interest taken by our readers in the purchase of the most desirable and economical teas for blending has decreased instead of increased as the margin of profit has from time to time declined; thus other channels have been opened for the sale of teas, and the competition thereby aggravated. There is still, however, room for a reasonable return being obtained by retailing good tea, the lowest price of a leading store being now 1s 4d for a pound, or 1s 2½d for half-ounces of fifty-six pounds, the highest price being 2s 9d, giving an average of 1s 2s upon the whole range of prices. This is, of course, a higher rate than many grocers can obtain, especially those who supply the wants of the poorer classes, but even with the lowest-priced teas the percentage of profit is worth having, and might

in some instances he increased if greater care were exercised in buying. There are a large number of grocers in country villages who are content to rely upon the judgment of the wholesale dealers in the important towns for the selection of the teas they supply their customers, and of course the intermediate profit reduces the net return to the small grocer. At the same time it must not be forgotten that during recent years many retailers have shown a partiality for the sale of packet teas, which, while it relieves them of all trouble of weighing up and packing, also the risk of storing tea in proximity to other articles which might injure loose tea, it encourages the sale of packet teas direct from London at lower prices. Teas which may be of good value are in many instances entirely unsuitable for the water in the district in which they are made into liquor. It is, therefore, desirable that country grocers should study these matters more than they do, and prevent the trade slipping away from them; they can still obtain a good price for their teas, and if they study quality and the effect of the water in their particular districts they should increase their trade. The consumption of tea last year was no less than 128 per cent more than in the previous one, and this increase is going on year by year, if not in the same proportion, still in a marked degree. Thus the trade has gone into a very important one, and if retailers would direct their attention to buying really desirable teas of good quality, and ascertain the wants of their customers better, they would have no occasion to regret the time and attention given. The result, both in towns and villages, would inevitably be a satisfactory increase in their sales, with a reasonable profit, considering this age of keen competition.—*H. and C. Mail*, Oct. 9th.

THE CEYLON TEA BOOM

Sweet, in the eyes of the Ceylon planter, are the uses of advertisement. The energetic Association to which he has confided his interests has shown during the past few months a most remarkable fertility of resource in compelling public attention in Europe and elsewhere to the virtues of Ceylon tea. Not only have the advertisement columns of the London Press rung the praises of this or that garden, but at the sale of produce in Mining Lane, the prices of certain selected samples have been forced up to abnormal amounts. The Tea Kiosk scheme of which much was expected has indeed proved a partial, if not a complete failure,* but it illustrates the restless activity with which those who are concerned in the development of Ceylon as a tea planting district are pushing the interest of the Colony. Another ingenious "notion"—to use an Americanism for which there is no British equivalent—is ascribed to a Mr. Elwood May, President of an Association known as the "Ceylon Planters' American Company." Mr. May has arranged with a Trans-Atlantic advertising Agent, "to secure 50,000 dollars worth of advertising in the American Press in return for 100,000 dols. of the Company's stock." By this arrangement, it is suggested that the editors and proprietors of some of the most influential American newspapers will be personally interested in the success of the Company, and may be induced to support it with the puff oblique, the puff direct, and the other ingenious improvements of Mr. Sheridan's list which are known to American journalism. Since, however, the proposed expenditure in this direction amounts, it is said, to about one-third of the Company's stock, it is difficult to understand how the Association in question can be expected to benefit thereby. This question does not, of course, affect the typical planter, who has all to gain by the advertisement of his wares. The Ceylon Planters' American Company, may or may not "wither," Ceylon tea will undoubtedly be "more and more." It is not to be expected moreover that such an excellent opportunity as that afforded by the Chicago Exhibition should be overlooked by the Association. Some £30,000 have already been voted from the Tea Fund for the

purpose of pushing the interests of Ceylon produce in the great show of 1893, and now it is announced that Sir Arthur Havelock's Government has added a further grant of £50,000. By the aid of this vote and judicious advertising on the part of the "American Company," it is expected that Ceylon tea will obtain a firm footing in the United States. This is one of the few markets in which neither India nor Ceylon produce has as yet made encouraging progress. In any case, the Ceylon Tea Planters' Association deserves to succeed.—*Calcutta Englishman*.

THE CULTIVATION OF PEARL SHELL AND PEARLS.

The Commissioner of Fisheries, Mr. W. Saville-Kent F.L.S., etc., who has been occupied during the past few weeks in investigating the fish and fisheries matters of the Northern district, returns south stopping at various coastal ports, by this morning's (Saturday's) boats from the Wellesley Islands (Group, in the extreme south west of the Gulf of Carpentaria, the Commissioner reports the indications of mother-of-pearl shell in such quantities as to justify anticipation of an extensive and profitable fishing being established there in the near future. Specimens gathered on the west shore of Swoor's Island more especially, were so fresh as to have portions of the living fish still adherent to them, showing that they must have grown in the near vicinity and indicating the probability of an extensive bed in the channel between Bentinck and Swears Islands. Traces of good shell were also obtained in the neighbourhood of the Norman River bar, and Mr. Saville-Kent is of the opinion that the greater part of the Gulf will ultimately prove a very profitable fishing ground.

Among the more interesting items that we have to chronicle in association with Mr. Kent's present sojourn in Thursday Island is his report concerning the highly satisfactory condition of those pearl shells laid down in the experimental nursery some two years since which have survived the onslaughts of the north-west gales and marauding natives. These have not only increased in size to an unexpected extent, but are also propagating, many young shells being now adherent to the old ones. Stimulated by the success that has attended the experiments at Vivien Point, attempts have been made at several of the shelving stations to bring in and cultivate the shell in like manner. At Wai-Weer, where the most gratifying results have been accomplished, Mr. Saville-Kent reports that the shell laid down has grown much more rapidly than in the Government nursery, inasmuch so that many of the shells which measured only four inches in diameter when first imported a little over a year ago, now measure as much as ten. Under such favorable conditions there can be but little doubt, as maintained by Mr. F. Summers, the experienced manager of the Wai-Weer Station, that pearl shell needs but eighteen months or two years to grow to marketable value.

In association with his periodical visits to Thursday Island within the past three years and establishment of a pearl-shell nursery, Mr. Saville-Kent has devoted some attention to the phenomena of pearl production. His experiments connected with this object have ultimately resulted in his obtaining such control over the natural constructive capacities of the shell-fish as to cause it by methods of artificial treatment to produce what are to all intents and purposes pearls of intrinsic commercial value. On such specimen that has been submitted to our inspection, while continuous with its shelly matrix after the manner of a pearl "blister," possesses a spheroidal symmetry and lustre that could be scarcely excelled and is, we are informed, of solid pearl matter throughout. The prospects and potentialities that are rendered possible by these useful experiments can scarcely be overestimated, and may lead to new and profitable developments of the pearl and pearl shell industry in association more especially with the leasing of suitable areas for the culti-

* Which is news to us in Ceylon.—*Ed T. A.*

vation of the shell for which facilities will be provided in the Bill drafted for Parliament.

This will, we understand, be Mr. Saville-Kent's last official visit to Thursday Island in connection with his present engagement by the Queensland Government. Mr. Kent has received an invitation from the West Australian Government to report and advise upon the pearl shell and other fisheries of that colony on the termination of his engagement here. He has however decided to return to England first for at least a year or two, for the purpose of supervising the publication of one or more comprehensive works on the fish and fisheries of Queensland.—*Torres Straits Pilot*, Aug 29th.

[The above refers, of course, to the large mother-of-pearl shells, but has a close bearing on the treatment of our small pearl oysters, for culture and pearl formation.—Ed. T. A.]

ECHOES OF SCIENCE.

Captive balloons seem to be peculiarly liable to be struck by lightning. Within the last six or seven years no fewer than three have been destroyed in this way, and the total number of them cannot be great. There was one struck at Turin, another at Barcelona, and, lastly, one at Chicago. Two of these, including that of Chicago, were struck when moored near the ground. Of course, a captive balloon in connection with the earth resembles the kite of Franklin, and is liable to "draw" the discharge, but the fact that it contains hydrogen, which is a far better conductor of electricity than air, may have something to do with the matter. The silk bag with hydrogen may be compared to a mass of metal enclosed in a thin layer of insulator. When, as happens in ill-made balloons, the gas escapes through the pores, the lightning is tempted in that direction. Giffard's impermeable balloons have not as yet been struck. It may be added that aeronauts, remembering the conductivity of hydrogen, should avoid opening the valves of their balloons while passing below a thunder cloud, in case they should precipitate the discharge.

It is well known that the valley of the Orinoco is connected to that of the Rio Negro by the Cassiquiaros river, and it is here that a party of explorers have recently discovered immense forests of the india-rubber trees, as well as other trees very like, if not identical, with the gutapercha trees of the Malay Archipelago. As the latter are all but extinct now, the news is all the more important.—*Globe*.

NOTES OF POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.L.S., F.G.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

Two French mineralogists, Messrs. Fouqué and Lévy, have produced micaceous trachyte by artificial means. The trachyte was obtained by the artificial action of water under pressure on a glass resulting from granite, and at a bright-red heat. The rock was homogeneous, and in its sections exhibited beautiful octahedral crystals of a variety of spiral, in connection with orthoclase and black mica.

An important paper was read before the Geological Society recently by Mr. J. J. Lister, on the geology of the Tonga Islands. Many are purely volcanic in structure, but there are some possessing undoubted stratified limestones crowded with marine shells, showing evidences of elevation from considerable depths of the sea. Mr. Lister also discovered genuine Plutonic rocks on the islands. The paper has an important bearing on the origin of coral reefs.

There is perhaps, not a more useful natural order of plants in the world than the cruciferae—our mustards, cresses, turnips, radishes, &c. All are remarkable for their pungency, and equally so for the localisation of this quality. Sometimes it is situated in one part sometimes in another. Moreover, it has long been

recognised as largely due to sulphur, and anybody who has had to do with the waste products of cruciferous plants, from cabbage water to rotten turnips, is well aware they freely give off a large quantity of sulphuretted hydrogen gas. A French agricultural chemist has just shown that the composition of the various active principles of the crucifera varies from species to species. Black mustard contains sinigrin, besides the ferment myrosin. The horse-radish does the same. White mustard contains sinalbin in place of sinigrin. The active principle of watercress is sulphocyanate of butyric alcohol. The roots, stems, leaves, &c., of other common cruciferous plants contain a mixture of sulphur and sulphocyanate of allyl. M. Guignard concludes that nearly all cruciferous plants are provided with special cells which contain a particular ferment known as myrosin; and that it is in the cells of their seeds this occurs most abundantly.

The methods by which plants obtain their nitrogen are always fruitful subjects of discussion and interest to botanists. Two German naturalists have recently published the results of some peculiar experiments, chiefly on the leaves of leguminous plants. They find that green leaves contain more nitrogen in the evening than on the following morning, and this appears to depend on the quantity of asparagin being larger. The reason given is that asparagin and sugar are the best nutrients for the fungus which lives symbiotically on the roots of most leguminous plants. The largest proportion of nitrogen present in the evening was in three common leguminous plants—*T. folium pratense* (or common clover), *Medicago sativa* (common medick), and *Lathyrus sylvesteris*. The same fact was noticed in connection with herbage plants belonging to other natural orders. The moral of this discovery seems to be that we ought to cut our hay at night, and not begin in the morning as is usually the case, if we wish it to contain the greatest quantity of nitrogen or feeding stuff.

Mr. Carus-Wilson has for some years past been studying the phenomena of "musical sand," or sand grains whose movements give out musical sounds. He writes in the *Chemical News* to say he has succeeded in producing musical notes from sand which was never before musical, and that he has obtained similar results from the mute or "killed" musical sands which have been temporarily deprived of their musical properties. Professor Crookes adds a note to Mr. Wilson's communication, stating he had witnessed that gentleman's experiments with musical sands, sands originally musical, musical sands which had been killed and then revived, and sands originally mute which had had the gift of music conferred upon them. Mr. Wilson will shortly explain these interesting phenomena in detail.—*Australasian*.

THE GREATEST BUTTER COW OF THE WORLD.

In our last September issue we gave an illustration of the celebrated Jersey cow "Eurotisama," describing her as the greatest butter cow of the world, she having produced the up till that time, unheard of amount of 915 pounds, 9 ounces of good merchantable butter within the year. We little thought, then, that within six months we should have to depose her from the pinnacle of fame, and rank her only second in the list, and yet such is our position to-day. The Holstein-Friesian cow "Pauline Paul," owned by J. B. Dutcher & Son, of Pauling, New York, has just completed a test of 365 days for butter production, and has made within that time the unparalleled record of 1,158 pounds, 15½ ounces of marketable butter, well washed, and salted at the rate of one ounce to the pound. We have not the details of the food consumed, beyond the fact that she was fed a ration composed of three parts bran, two parts ground oats, and one part corn meal, by measure. Of this mixture, she was fed per day not exceeding twenty-seven pounds, to which was added three pounds of cotton seed. She had neither slop nor

ensilage. We do not know what hay or grass she was fed, but presume she would have what she would eat of these foods. She came through the test in good condition, and was never a day "off her feed." She gave during the time 18,669 pounds, 9 ounces of milk, or an average of 16.17 pounds of milk for a pound of butter. The cow weighs 1,450 pounds, and she therefore produced in the year, nearly four-fifths of her own weight in butter. Her butter, at twenty-five cents per pound, was worth \$288.75. Taking the cost of her grain ration, at an average of \$1.00 per hundred pounds, the total would be \$109.50. To this must be added the hay or other forage which would net, we assume, be more than the weight which would have sufficed to feed any other cow of a similar size, and could not therefore well have cost more than \$30. Together, therefore, the whole cost of the keep would not be more than \$139.50, as against a butter production alone worth \$288.75, and to which should be added the value of the skim milk, her calf, and the manure. The milk and manure alone would pay for the forage and her care, whilst the calf from such a cow would be worth a small fortune. Without taking these items at all into the account, there is shown a net profit of \$179.25; and yet in the face of such a record as this, there are to be found men who say "keep scrubs!" What astonishes us most in the matter, is that a Holstein cow has been found to make such a record, as hitherto their strong point has been milk, not butter. It only, however, goes to show what can be done by selection and breeding for a purpose. In the future, the Holsteins must take rank as butter cows along with the Jersey, and the battle will now be between the two breeds, and not as between Jersey and Jersey. With the continuance of such a rivalry, who shall say that the days of the "scrub" are not numbered. No farmer with a knowledge of what is possible from thoroughbred or graded stock, will, for a moment, hesitate to clear out the "scrubs," and replace them with a reduced number of better stock; in fact, to apply the intensive system to his stock as well as to his farm. We say "God speed" to such a course. It can only result in advantage to the man who pursues it.

MINOR INDUSTRIES IN THE EAST
BAMBOOS AND THEIR USES,

As thus treated by the editor of the Trinidad Agricultural Record:—

One staple advocate in Trinidad has always a covert sneer for "Minor Industries," and by that token they understand any cultivation new to the Colony, no matter what may be its prospect of future development. The poor down-trodden planter (as the West Indian in London terms him (who can he mean?) must not be disturbed, and labourers must not leave the station to which God has been pleased to call them.

The "poor down-trodden," may help him—even against his will! Pens and sugar estates which were unsaleable a few years ago have in that rising Colony increased in value five and six-fold owing to a "minor industry"—bananas. The purchase-money of a mortgaged sugar estate the other day was subscribed in Kingston in five hours, for the purpose of planting bananas. The amount subscribed was \$150,000.

In contrast to the incredulity and cynicism of some of our people see how the minor (minimum if you like) industries are pushed in the East. We have heard of bamboos as a paper material: it was to have been tried the other day in Demerara, and Sir John Gorrie at the late Exhibition showed how they could be utilised, with a coating of Trinidad pitch, as subsoil drains or for verandah posts, etc. The following price list of bamboos imported from Singapore and other eastern ports will give some idea as to the variety of economic uses, what we regard as trifling objects, can be applied in a Great Country like England:—

N.B.—The giant bamboos of Trinidad would be decidedly novel in Europe, and it was suggested to us that they might come into considerable demand.

The giant bamboo, which flourishes in Ceylon from sea level to over 5,000 feet altitude, has been used in sections coated with tar as roofing tiles, for such they are rather than shingles. Well preserved too, by asphalts or petroleum, there is no reason why they should not be used for many other purposes, above and underground.

THE FOCHOW TEA TRADE.

The annual Consular report for 1890 says:—

The great falling off in the export of tea again constitutes, as it has done for some years now, the one all-absorbing feature of the trade during 1890. In round numbers this decline amounts to 67,000 piculs, and is made up of decreases of 31,000 piculs to England and 36,000 piculs to the Australian colonies. In 1890, the year when it reached its highest figure, the report from Fochow was 737,000 piculs, in 1886 it was 665,000 piculs, and since then it has steadily and rapidly declined to 616,000 piculs in 1887, 553,000 piculs in 1888, 457,000 piculs in 1889, and 390,000 piculs in 1890. The difference between 1886, which may be called an average year, and 1890 (275,000 piculs), represents a decrease in the year's earnings to the people of this neighbourhood of some four million taels, and to this Government a diminution in the export duty and *tekin* revenues of over one million taels. The present position is this: India and Ceylon have certainly succeeded in beating net only the lower but also some of the better grades of Fochow teas in both price and (London rated) quality, and are fast alienating from us our best markets—England and its colonies. Although really good tea still finds a buyer, yet the majority of Fochow teas no longer come up to the London standard, and are bought "for price" only, that is at a price some 25 per cent. cheaper than the equivalent quality of Indian tea. The poorer and cheaper grades are required in London exclusively for mixing with Indian teas. Their cheapness seems to reduce the higher price, and their smooth tone helps to lessen the strong flavour of their Indian rivals. This mixture is the beverage of the day, and is sold throughout England under the name of Indian tea. These facts show conclusively that the outcry of the Fochow merchants for better and stronger tea is justified, for such a tea would not only hold

its own, but would deprive the Indian product of an important cheapening and diluting agent, and force it to stand on its own merits. Unfortunately, Foochow, in the rush after fortune, has for years past paid less and less attention to quality. Easy and sometimes fabulous returns stimulated over-production, over production depressed prices, and depressed prices further depressed quality to such a point that younger rivals could step in, and with the aid of scientific appliances which ensure more uniform manipulation and results and greater independence from seasons and weather, wrest from China the last of its ancient monopolies. The outlook is gloomy indeed. Many of the old famous districts are stocked with old used up trees; the present generation grown up in a time of prosperous over-production, lack the experience, carefulness, and patience of the old tea planters; and with depressed prices, depressed markets, and annually declining demands, where is the stimulus to come from for that improvement which alone can reconquer the lost position? In this emergency it is generally felt that the Government alone can help; without its intervention, aid, or permission, no change can be effected and it is therefore with anxious interest that its action is looked forward to by the tea merchants of this port. In 1889 the losses of the native teamen were computed at \$3,000,000, and this year their losses are held to be even greater than last year. While the year 1889 was disastrous to both Chinese and foreign merchants, of which latter no less than seven firms either closed or failed, the present year has fallen heavily upon the Chinese chiefly, and, in the consequence, has witnessed the withdrawal of four native tea merchants, and the failures of seven opium merchants, two tea longes, and two piece good firms—fifteen firms in all. In sympathy with this general depression, the value of foreign houses property has declined enormously, a large number of offices and warehouses are standing empty, and rents have declined fully 50 per cent.—*L. and C. Express.*

THE uses of the electric light appear to be endless. The latest American proposal is to gather fruit after nightfall, electric lights being utilised for the needed illumination. "There is certainly no reason why this should not be done," says an exchange. "Fruit that is gathered during daytime is so heated that it needs to be cooled off before it is packed in cars for Eastern shipment. This would be obviated by gathering the fruit at night. The pickers would doubtless prefer the night work as well, the absence of the extreme heat of the sun felt during the day being most grateful. There are times, too, when the fruit ripens so rapidly that much is lost which could be saved were the gathering to go on continuously day and night."—*Mildura Cultivator.*

MR ROBERTS ON THE QUALITY OF 'CEYLON TEA.—Meeting Mr. Roberts, whose authority upon all questions connected with your teas you know I set such a high value upon, he told me in reply to my query as regards the low prices of late obtainable from your teas that, although, undoubtedly, the quality of those of late sent home had been very inferior, yet that it would be a mistake to assign to that reason solely the unremunerativeness of the rates obtained:—"We are too apt," he said, "to assign these bad times wholly to quality. We overlook the many other conditions which affect the market. Tightness in money, for instance, will often restrict buying for a time, and there are a thousand and one other causes which may operate to depress prices. Still, your planters should not send such a large bulk of bad stuff as we have recently received. It hangs on hand dreadfully. Fortunately the later shipments have greatly improved, and at the present moment there is little or no reason for grumbling at the quality of the Ceylon teas reaching us, and the market for these is now improving and seems to have a steady upward tendency, though I should not like just at present to speak with certainty as to its continuance."—*London Cor.*

Low pruning is advised by some fruitgrowers because more of the fruit can then be picked by standing on the ground, which is cheaper and easier. When trees are low pruned there are also few windfalls, the tree gets a better growth, is less liable to blow over, and, the ground being shaded around the roots, it grows faster. Low branches keep the ground moist and in better condition for cultivation.—*Mildura Cultivator.*

TEA AND COFFEE IN SARAWAK.—Consul Trovonen, reporting on a visit to Sarawak, made by invitation of the Rajah of Sarawak, states:—"There are 115 acres under coffee, and 50 acres under tea, while 70 acres more are being planted with the latter. These plantations, like all experimental cultivation in Sarawak, are Government estates, and are owing to the initiative of the Rajah.—*L. and C. Express.*

THE Government Botanist, Madras, has been directed by Government to submit a programme for the botanical survey of the several Districts and provinces assigned to him in the general scheme for a botanical survey of India, with an estimate of the cost of carrying out the survey. Mr. Lawson will prepare his programme in consultation with Dr. King of the Calcutta Botanical Gardens, and Dr. Trimen, Director of the Botanical Gardens in Ceylon.—*M. Mail.*

HOP TEA.—Representatives of the Press were yesterday invited to Maidstone to inspect the works of the Hop Tea Company, the foreign patents of which have been acquired by the Hop Tea Foreign and Colonial Syndicate (Limited). The Company claim that by mixing the hops with Indian and Ceylon tea the flavour of the tea is not only improved by giving it a malty aroma, but that hops, being a sedative, counteract the too-exciting effect of the tea upon the nerves, and while preventing waste of nervous energy promote intellectual activity.—*L. & C. Express, Oct. 16th.*

A PHOTOGRAPH recently reproduced in the *North Western Lumberman* showed a redwood plank of extraordinary size, measuring sixteen feet five inches in width by twelve feet nine inches in length and five inches in thickness. It was cut from a tree thirty-five feet in diameter and three hundred feet tall, being hewn out of the stump after the tree was cut at about twenty-eight feet above the ground. A locomotive, attached to a block and tackle, was needed to lower it, and two men were occupied for a month in roughly preparing it for shipment. The price of this labor, added to the cost of transportation, amounted to some \$3,000, after the plank had been taken by water to San Francisco. The tree stood in Humboldt County, California, and the plank, after being exhibited in various cities, will probably be a feature of the World's Fair at Chicago. A specially constructed car is required for its transportation.—*Garden and Forest.*

CAPACITY OF TODDY-YIELDING TREES.—A series of experiments have been conducted by the Madras Akbari Department to test the yield of the various toddy-yielding palms. The experiments show that the sage palm heads the list with an average yield of 130 gallons per year. This palm is only tapped in the Malabar District, and the agency tracts of the Northern Circars. The coconut palm yields on an average about 70 gallons a year, and the yield is continuous. In Malabar, the land of the coconut, the quantity is greater than anywhere else; then follow Coimbatore, Trichinopoly, South Canara, Tanjore and South Arcot. The yield of palmyra and date palms is about 90 gallons a year, but varies considerably in different localities. In Palghat the palmyra yields about 90 gallons in a season, while at Tuticorin and Kuttangall it is only about 15 gallons. In the case of dates the yields at Villapuram is 59 gallons, while it is as low as 8 gallons at Mogaltur, the extreme dryness of the country around Tuticorin and Mogaltur being accountable for the difference.—*Madras Mail.*

AN AGRICULTURAL COLLEGE FOR TRINIDAD

is suggested in the *Agricultural Record* for August in an elaborate article by the editor, entitled

Report of the Technical and Practical Teaching of Agriculture in England and Belgium, with suggestions for the formation of a School in Trinidad.

After stating and reviewing the systems of agricultural teaching in Britain and Belgium, the question of a local institution is thus dealt with:—

A comparison between the English and Belgian system is very instructive. In England where so much has been done by private munificence or corporate bodies, not only in agricultural education, but also in the arts and sciences, the learned professions, in charities and other public matters. In Belgium on the contrary the State taking everything into its own hands. One result of the English system is, as I have already mentioned, that there is no uniform system of teaching, or standard of qualification, the tendency being rather to aim at the *minimum* and so-called *practical attainments*. In Trinidad it is especially useful to study these different systems, and most people will admit that while in both countries education is as far-reaching as possible, that in this Colony with its struggling and undeveloped industries and its numerous and uneducated class of small proprietors and the complete absence of private enterprise, the sugar proprietors excepted (they being all absentees) a scheme of education in Agriculture should be framed more after the Belgian system, this being less devoted to dairy work, stock, and minor matters, which could be learned anywhere, and do not immediately concern us. Another illusion would be dispelled which has been hitherto a complete stumbling-block in the way of establishing a school in Trinidad, viz: that a Model Farm must enter into any project of the kind. It will be seen that both in England and Belgium it is found better and cheaper to obtain assistance in practical teaching from neighbouring estates, and it will come like a revelation to some, that all the essentials for a first class Agricultural College already exist in Trinidad and more or less in the other West Indian Colonies. Another important consideration (in both countries) is the importance attached to instruction for schoolmasters and rural teaching (for peasants) by means of itinerant professors, and lectures, and demonstrations. Nowhere in the world is there a greater wealth of vegetation, combined with dense ignorance of the elementary laws of plant life, and scientific culture than in the West Indies, and it would well repay any amount of expense and trouble if a better knowledge of the selection of seed, grafting, and pruning, treatment of blight and the more skillful preparation of the various products could be instilled into the rural population in these parts. The present means of teaching available in Trinidad as referred to, comprises:

1. A well furnished Chemical Laboratory.
2. A well appointed Botanic Garden with all sorts of Horticultural operations always going on and a perfect Herbarium.
3. A very complete Government Dairy and Stock Farm.
4. The Experimental Farm at Chaguana, proved to be suitable, and which should be used as a depot and school of forestry.
5. Technical teaching by Officers of the Public Works Department in land measurement, surveying, etc. *
6. The assistance of adjacent estates of which many accomplished Managers would no doubt willingly assist.

* In Grenada Sir W. H. Hutchinson, whose efforts to improve the well-being of all classes under his government are cynically termed "philanthropic" by the "West Indian in London," suggests that the Public Works Department might serve as a technical school in many branches of trade; if so, there is no doubt that the South Kensington authorities would render every assistance, and in Trinidad this suggestion would fall in with the educational scheme of the Victoria Institute.

7. The propinquity of the Catholic, and Royal Colleges, and Nopingu Schools to the Victoria Institute, of which the Agricultural School would form a part.

If the syllabus of South Kensington is adopted, some modifications would have to be introduced, and if the Trinidad scheme is brought under their system of examination, some special forms of questions would have to be devised, bearing on tropical Agriculture.

Our present colonial staff would be sufficient, with the addition of a Professor of Agriculture, having as a speciality Entomology, Economic Geology, Physics, Drawing, etc. It should be his business also to undertake peripatetic work in the most important rural districts. The subdivision of the different courses of lectures etc., would be a very simple matter of detail. Students passing in honours should be sent for one year either to Belgium, London (Cambridge) or the United States, and part of the money of the present Classical Scholarships might be devoted to this purpose.

The College would be very nearly self-supporting if a moderate fee was required from the pupils, although the Government would naturally be chargeable for itinerant teaching, and for the courses for schoolmasters. Inasmuch the Professor of Agriculture would be somewhat of a specialist and confer great public benefit by studying the various insects, fungi, etc., which affect our crops, his salary ought to be charged to the Government.

Another important matter would be the compilation of suitable text-books. This might be easily done after the model of Professor Tanner's excellent little work, if his permission could be obtained.

The course of lectures given by the different teachers should be printed in the shape of notes.

PEARL SHELL AND BECHE-DE-MER FISHERIES.

The Commissioner of Fisheries, Mr. W. Saville-Kent, F.L.S., &c., has returned to Brisbane by the Cintra from his extended Northern tour. Among the more prominent results accomplished in connection with his trip, that of the discovery of mother-of-pearl shell in considerable abundance in the vicinity of the Wellesley Islands, in the Gulf of Carpentaria, and also the continued success of the pearl shell nursery established by the Commissioner of Fisheries at Thursday Island over two years ago, have been already recorded. Mr. Saville-Kent has devoted a considerable interval on this occasion to visiting the béche-de-mer stations throughout the Great Barrier system, the result of which will take the form of a report for the consideration of the Government, embracing a comprehensive scheme for the subdivision of the entire béche-de-mer producing grounds into sectional areas, to be let on lease by public auction or to be placed temporarily in reserve for resuscitation, as may seem desirable, on lines corresponding generally with those upon which the oyster fisheries are conducted. A searching investigation has proved beyond question that the béche-de-mer grounds are much overfished, more particularly in the neighbourhood of the shipping ports, and where they are necessarily of most easy access. The opinion obtained from the leading boat and station owners engaged in this trade is greatly in favour of the new regulations suggested, and the carrying out of which is calculated to add substantially to both the intrinsic value of the fishery and to the revenue returns. A *sine qua non* of the new régime proposed will be the appointment of district inspectors and the systematic patrol of the fishing grounds, and the need for this is already widely recognised on independent grounds, and in the interests of both the employers and the native labourers engaged in the fishery.

* In Grenada I am informed that it is proposed to engage a Professor of Entomology to study this subject especially, with a view of finding remedies for the destruction of such as affect the different crops of that island.

Among matters connected with the oyster fisheries, Mr. Saville-Kent announces that the tropical oysters figured and described in his recently issued report on the oysters and oyster fisheries of Queensland as the black-lipped species, and to which he had previously drawn attention as a wholesome edible variety, is already being turned to commercial account in the far North, consignments being regularly shipped for the Normanton and Croydon markets. In addition to the subjects above mentioned, Mr. Saville-Kent has accumulated in connection with his recent tour much valuable information and material for utilisation in his projected comprehensive works on the fish fauna and fisheries products generally of this colony.

THE NEW BILL.

The Pearlshell and Beche-de-mer Fishery Act Amendment Act of 1891, initiated in committee by Sir Thomas M'Ilwraith, provides for the appointment of inspectors, and enacts that all ships employed in the trade must clear the Customs before going to the fishery, and forbids any vessel to carry more than two gallons of intoxicating liquor. The inspectors are empowered to board any ship or boat employed in the fishery, or enter upon any fishing station or any buildings thereon; to require the master or other person in charge to produce and deliver up any certificate or document relating to the ship or boat, or to any person who is employed; to muster the persons employed on board the ship, or boat, or at the station; to require the master or employer, or the person in charge of the station, to give any explanation concerning the ship, boat, or station, or men employed; to examine all the appliances, the diving dress, air pump, air-tubes, &c., and may by order in writing forbid the further use of it if, in his opinion, it is unsafe or insufficient. Provision is made for appeal from the inspector's decision. It is also provided that periodical inspection of diving gear shall be made by the inspectors every six months, the maximum and minimum penalties attaching to the offence of non-submission on the part of the master or employer being £100 and £20 respectively. The maximum penalty for using condemned gear is £50. Should it appear to an inspector that a contravention of any of the provisions of the Acts has been made the inspector has power, without summons, warrant, or other process, to take the offender and if necessary the ship or boat to which he belongs and the crew before a justice, either at a place appointed for holding courts of petty sessions or not, and the inspector may detain the ship or boat until the alleged contravention has been adjudicated upon. Any person who removes, except for the purposes of cultivation only within the colony, or sells or exposes for sale, any pearl oyster shell of the kind scientifically known as *Meleagrina margaritifera*, and of either of the varieties commonly known as "golden-edge" and "silver-lip," of which the more or mother-of-pearl measures less than 6in. from the butt or hinge to the opposite edge or lip, is made liable to a penalty not exceeding five pounds for every such pearl oyster shell found in his possession, and every bag or other receptacle containing shell in which any such shell is found, and every heap or other collection of shells in which any such shell is found, is to be forfeited. If, however, it is proved to the satisfaction of the Governor-in-Council that the ordinary size of any such pearl oyster shell when full grown is, when found within any specified territorial waters of Queensland, of less size than that hereby prescribed, the Governor-in-Council can by proclamation direct that with respect to any such pearlshell found within those waters other dimensions shall be substituted. In this connection it is also provided that in the case of any such pearl oyster shell of the variety commonly called "dwarf shell," an inspector may, on application, at his discretion authorise its removal or sale or exposition for sale notwithstanding that it is of less size than that prescribed. All shell must be packed in receptacles for exportation at some place on land, but this cannot be done until one week's notice of intention to back has been given to the inspector. The maximum penalty for an offence against this clause is £20. Provision is also made for the closing of barks.

Yearly licenses must be taken out by dealers in pearls, the fee being £5; and after December of the present year it is made unlawful for any person to purchase pearls at any place where the fishery is carried on, or, at Port Kennedy in Thursday Island, without having first obtained this license. It is provided that the Governor-in-Council may grant a lease of the whole or any part of an outlying reef or bank, or other places for the collection, storage, cultivation or propagation of pearlshell or of beche-de-mer, or of sponges or other products of the sea. The remaining clauses of the measure deal with the penalties to be inflicted on persons obstructing inspectors, the service of proceedings and make the master of the ship *prima facie* liable for offences committed by persons employed thereon.—*Queenslander*.

THE CONDITION OF SARAWAK.—An interesting report by the British Consul at Brunei, in Borneo, on a visit which he made recently to the State of Sarawak has just been issued by the Foreign Office. The first town visited was Muka, the centre of the sago industry. The stems of the sago palm are cut in the upper reaches of the river, formed into rafts, and floated down to Muka, where the pith is extracted, and stamped on floors in such a manner that it falls in the shape of flour into boats placed below to receive it. The flour is then shipped to Kuching or Singapore, where it is again cleaned and shipped to its destination. Kuching, the capital of the State, is described as a model of cleanliness and good order, possessing an excellent hospital and museum and various educational institutions. Busoh and Paku, in Upper Sarawak, were next visited; at the former are extensive antimony works, and at the latter the Chinese work gold. The quartz containing the gold is either picked or blasted from clefts in the limestone rocks* and conveyed to sheds, where it is broken with a hammer worked by the foot, after the manner of a sewing machine, upon a granite anvil, into a fine dust, which is washed in sluices, and the residue carefully "cradled," as in Australia. Throughout Upper Sarawak there are various experimental Government plantations; those of pepper, tea, and coffee are doing well, while tobacco has proved a failure. The Sadong coal mines are being worked to advantage and the product exported. The Consul then went to Sibn, on the Rajang river, the largest stream in the State, and one of the largest in Borneo, for it is navigable for vessels drawing 7ft. to about 160 miles from its mouth. Sibn is the largest out-station in Borneo, with a large population of Chinese traders, who exchange European goods for jungle produce. The native population of the district is about 70,000, mostly Dyaks, but some idea of the diversity of the population will be derived from the fact that 17 different languages are spoken on the Rajang alone. The dyaks of the district were amongst the most formidable piratical hands infesting the coasts of Borneo less than 50 years ago. There is a considerable timber trade from the Rajang. The Sarawak coast is well lighted, and the Consul reports that he found everywhere a thriving and contented population, while the European officers engaged in the administration are, in his opinion, equal in every respect to those serving her Majesty in similar capacities. The revenue last year was \$413,112, and the expenditure about \$50,000 less. The revenue is derived from opium, arrack, gambling and pawnbroking monopolies, and customs. The total foreign trade last year amounted to over 4½ million dollars. The chief items of export were sago flour, \$343,035; gatta-perohn, \$241,595; pepper, \$237,476; rattana, \$173,933; and gambier, \$133,235; while the chief imports last year were rice, \$240,426; cloth, \$237,737; and treasure, \$168,063. The general impression left by the report is that of a well ordered, peaceful, progressive State, with light taxation, all of an indirect character, and an expenditure which is less than the revenue by a substantial sum.—*London Times*.

* Auriferous granitic in clefts of limestone rock is, surely, a very rare formation?—*Bo. T. J.*

THE ROYAL, BOTANICAL GARDENS, PERADENIYA, AS AN EDUCATIONAL INSTITUTION.

In noticing the sums appropriated in the estimates of 1892 to the support of the beautiful Gardens at Peradeniya, of which Ceylon is so justly proud, we expressed regret that the extensive library, the herbarium and the museum of timber and other specimens should be separated by so considerable a distance from the chief city of the island, with its colleges and schools. This regret was felt in view of the obstacles which the distance and the expenditure of time and money in travelling placed in the way of students desirous of availing themselves of the important and interesting aids to education connected with the Gardens, in addition to the education of the physical as well as the mental powers involved in wandering through the beautiful grounds and identifying, by means of the inscribed tablets, the numerous and varied plants indigenous to Ceylon, or introduced from so many countries and climes,—tropical, sub-tropical and even temperate. We judged, and as it turns out rightly, that the Government and garden authorities were not only willing but anxious that all respectable persons, whose objects were *bona fide*, should, on expressing their desire, have access to the books, the coloured drawings and the specimens of plants, timbers and other objects connected with or illustrative of the science of botany, collected at Peradeniya. Natives of the island and especially the class of European descendants who have advanced and are advancing so rapidly in recent years by means of the educational advantages placed within their reach by the liberality of Government,—and let us add the zeal of the various Christian bodies in our midst,—are, naturally, sensitive to the reception they meet with at the hands of Europeans and especially European officials. This sensitiveness sometimes leads to misconception as to bearing and language and to effence being taken where none was meant. Officials pre-occupied with work which it is their first duty to carry through may seem brusque, when they are merely anxious to economize valuable time. These remarks apply to a communication which has reached us from a very estimable and learned Ceylonese, who is engaged in educational work in connection with a high-class institution. We submitted his letter to Dr. Trimen, and, at that gentleman's instance, we publish it with the Director's reply addressed to ourselves. The incident is not to be regretted, seeing that it has drawn forth so explicit and satisfactory a statement corroborative of our previously expressed opinion, that the Director of the Peradeniya Gardens is not only willing but anxious to aid those desirous of availing themselves of the advantages to them as students, or (we doubt not) as persons desirous of adding to their stock of general information,—of the scientific literature and Museum collections collected in the Royal Botanical Gardens. Our correspondent wrote:—

"I was delighted to read your leader of the 21st when speaking of the Supply Bill for 1892 you referred to the Botanic Garden at Peradeniya. You say 'a great means of education for the young and of information for students of more mature age is largely restricted in its usefulness'—owing to the distance of Peradeniya from Colombo. Now, sir, I have a real hardship to put before you. I have long been full of botanical enthusiasm though not a professed botanist, and derive a great deal of pleasure from turning over botanical journals and magazines. Now at Peradeniya there are of course those books. There is besides the vast and most interesting *Hortus Malabaricus*. Well on going

to the Museum and stating that I wished to see the library the Director left me under the impression that I was simply *tolerated* not welcomed there, and I turned over the pages (if I even had the courage and audacity to do such a daring thing) with the fear that I was making myself a nuisance to the learned Director. He seemed to think that there could be nothing in the library to interest the general reader, and that the collection of timbers would be all that I could possibly enjoy! He little knew that it was *all the other way*. Your acquaintance with the Director would perhaps lead you to quite another conclusion, and I hesitate therefore to send a communication direct for publication. All I wish therefore is to have it established that not only the beautiful garden is made free of all who go there, but that those who wish to consult the journals and books should be allowed free liberty to do so without feeling that they are in anybody's way and that their presence is more an impertinence than anything else. I do not for one single moment ask that the Director should be obliged to turn away from his duties to administer a botanical lecture, though should be only be willing to do it he would be conferring an immense benefit on the rising generation. It is not often that he will, have the opportunity of thus supplementing the labours of the botanical teachers in our colleges and schools. Let the museum be more than a collection of objects. Let it be a rich source of pleasure and instruction. I believe it was the fact that the Lady Principal of the Kandy Wesleyan Girls' School took her pupils to the Gardens and made the subject of Botany so real that secured such good results at the last Cambridge Local.

"The Director's office and working room adjoins the Museum Library. (He has another room with his own private collection of botanical books to which of course the public have no right.) The floor too is (I believe) *boarded*; and no doubt if a teacher, say, with his pupils goes to the Museum and introduces the treasures in the Library to his pupils, giving them a few hints here and there, he would feel that to a certain extent he would be distracting the learned Director in the next room. Can not some arrangement be made whereby this difficulty may be obviated? Is it necessary that the library should be separated from the working room of the Director by only a wooden partition?

"I beg on behalf of all lovers of nature and of the beautiful that you will give the subject a thought, and without any charge being made against the present learned Director of discourtesy that you will plead that every facility be given to people to make their researches in the records of the Museum Library, and even, *under proper safeguards*, to have the opportunity of burrowing for a day or two any book from which they may like to make extracts. [Perhaps this latter may not be practicable.]

"Excepting the Museum at Peradeniya there is no other place in the colony where botanical journals could be perused, and should the slightest (however unintentional) obstacle be put in the way of persons craving for botanical knowledge what a great hardship it must be!"

Dr. Trimen's frank and satisfactory response is as follows:—

"I am much indebted to you for forwarding to me your correspondent's letter, and must say at once that I feel greatly pained that he should have received such an impression as he describes from his visit to Peradeniya. I hope and believe he stands alone in this, and am quite at a loss to understand how it came about. It must be surely unnecessary for me to say that everyone wishing to study at Peradeniya is not only free to do so, but very welcome and not the least 'in the way.'

"Unfortunately I cannot clearly recall Mr. ———'s visit. I suppose I must have been pressed with the work when he came; but even in that case, I am certain that whatever be wished to see would have been freely placed at his disposal. He could not have made his wants plain to me.

"I should like to take this opportunity of saying, what I supposed was well-known, that the Government Herbarium and Library at Peradeniya are *absolutely public* in the only sense in which valuable scientific collections can be; that is, they are freely open for consultation by all who wish to use them for purposes of study, and ask permission to do so. It has always been my effort and my desire to make them more and more useful in this way, and I should indeed be sorry to think that any imaginary obstacles were hindering my progress.

"You are quite at liberty to publish any or all of this letter; indeed if you think it well to give it publicity to Mr. ———'s complaint, I hope you will, by giving also my answer, help to convince him that his "real hardship" exists only in his own imagination."

We hope this statement will not only be satisfactory to our correspondent but encouraging to others who may wish to consult the books in the Library and specimens in the Museum at Peradeniya.

YIELD PER ACRE OF TEA IN CEYLON AND COST OF PRODUCTION.

The following letter has reached us:—

Tunisgalla, Rangala, Oct. 23th.

"Dear Sir,—I have just read over in *Observer* of Sept. 10th 1883, Mr. Armstrong's lecture on tea. If you will compare his forecast, and the present, actual output and results of working, an interesting article might be edited.

The yield of tea per acre is obtained, but at a far lower cost, say 26 ct. per lb. f. o. b.—Yours faithfully

H. W. HORNBY.

There can be no question that the yield of tea, in the hot, damp and forcing climate of Ceylon has exceeded the most sanguine expectations, some exceptional and specially rich alluvials in Bogawantalawa and the Kelani Valley, showing returns up to 1,700 per acre, while all the world knows the wonderful averages obtained from appreciable areas of manured land on Mariawatte, considerably in excess of 1,000 lb. per acre. Indeed it is owing to a sport of what we suppose we may call *over-bearing* in the larger portion of our tea regions in the latter portion of last year, that prices for some time back have been at so low a level. Our correspondent, in noticing the lower cost at which tea is now placed f. o. b., ought not to have forgotten the steady, and recently the very material fall in the prices of our staple product since Mr. Armstrong delivered his valuable and interesting lecture. That lecture was delivered in August 1883, and it was revised and supplemented in October 1884, seven years ago. The advance since then in the successive crops and in the supersession of hand labour by machinery, has been rapid beyond the precedent in any tea growing country. Before coming to the figures for cost of production we cannot help quoting some of Mr. Armstrong's shrewd and well-informed remarks on other subjects:—

I consider our knowledge of coffee cultivation goes very far to aid us in that of tea, and, with our trained labor, most apt at picking up anything new, to aid us, we can place our tea in the market cheaper than any other tea producing country in the world.

My remarks today have mere especial reference to the cultivation of tea in what may be termed our coffee zone, in fact, to the practicability of tea taking the place, in some instances, of coffee, or of its being planted in forest land adjoining our coffee estate, and which we have thought too high for coffee.

Throughout this paper I refer to Assam-Hybrid tea only.

At what elevations will tea grow at, in Ceylon, to pay? From almost sea-level to over 6,000 ft. provided soil and aspect are suitable.

SOIL.—Should be fairly good—the richer the better—deep and friable, loam well mixed with sand; a shallow

quartz soil is good. Tea will not flush readily in this although it may grow to a fair sized bush. A sabb soil, well mixed with sand, or grit, without showing a very good surface soil, will, although giving a slower growth at first, turn out a better paying soil than one with a rich surface and clearly defined clayey subsoil without an admixture of sand; the more we pluck, the deeper the roots must go, and we must have room for them. The higher our elevation the richer should our soil be, to make up for climate.

CLIMATE.—That which is best for coffee will I believe, for a permanency, be found to be the best for tea. The head ideal of a tea climate is Awisawella, Yatiyantota and lower portions of Morawakorale, also portions of Ambagamawa; but they have not our coffee zone subsoil, as a whole; and our zone will I think, make up, in its despot soil, for the want of extreme heat with moisture, which prevails in these districts, where, however, tea will rapidly make a fortune for its lucky proprietors.

The higher the elevation, the less rainfall is required, and *vice versa*, light showers alternating with sun, if we could order them so would give us 1,000 lb. per acre at 5,000 ft. elevation. At the higher elevation, continued rain at the height of the monsoon has the same effect in checking the flush, for the time being, as a long continuance of sun has in the low country. Perhaps a good thing; for, with us the bush has no wintering, and the only rest that of a 10 lb. plucking, instead of a 2 lb.

After quoting very encouraging yields of tea at different elevations, Mr. Armstrong thus summed up on the question of yield:—

Young as we are, and in the face of these yields at 6 years of age and upwards I feel perfectly safe in estimating an *average* yield of 400 lb. per acre from tea in the coffee zone and above it, say from 2,500 to 5,700 ft. in sheltered situations, and in saying 5,700 ft. I do not wish it to be understood I draw the limit even here, but the figures I have had given me above this elevation viz. at 6,300 ft. are only from a very small area under tea, which however gave at 6 years old 400 lb. per acre at 4 x 4. For low country teas, that is teas at from 2,500 down to sea level, at 6 years old and upwards, I shall be very much surprised indeed if they do not show an *average* yield of 600 lb. per acre. These estimates gentlemen, may seem excessive, looking at the average yields from Assam and India generally, but compare our yield in this our very infancy with that in India and you will find we can even now show an average, from estates at 3½ years old up to 6 which will more than double theirs. [30th October 1883].—N. B. The yields of this season have proved this estimate to be under the mark, as we have to chronicle yields of from 600 up to 900 lb. per acre all round at high low, and medium elevations, and in the face of a bad season, from insufficient rain, through out the island.] Inclemency of weather does not affect us in the same way in which it does our Indian farmers, as we have 11 months in which we pluck. If one month is too wet we benefit all the more when the sun shines again as we have lots of time; if we have a spell of dry weather, on the other hand, this again is sure to be followed by rain, when we at once make up any loss.

He then came to the question of

COST PER LB. F. O. B.—I have to thank many friends for furnishing me with cost F. O. B. at Colombo and choose the following which are representative of all and may be relied on. In all cases, the tea was manufactured without the aid of machinery of any kind.

150 lb. per acre cost	36s. f. o. b.	} Including cost of upkeep of young tea not in bearing.
700 do do	30c. do	
400 do do	40c. do	
130 do do	29c. do	

If we take the average of the above 4 estates we have, say 495 lb. per acre hand-made, costing 31 cents f. o. b. at Colombo; London charges including freight are under 2½d; but for all practical purposes let us say 2½d, the above teas at an average price of 1s 2½d, and this is not a high average, leaves us 1s nett, or at 1s 8d per rupee, 60 cents; a profit of 26 cents per lb. at 495 lb. per acre, say Rs 128-70 profit per acre.

It will thus be seen that Mr. Armstrong's result for hand prepared tea was 34 cents per lb. With the use of machinery the figure was reduced by 4 cents in October 1844, the cost of plucking and manufacturing by machinery showing a saving per lb. of tea of 6-34 cents, as against hand rolling and charcoal firing. Mr. Armstrong's estimate was then for machiuo made tea 30 cents per lb. f.o.b. at Colombo, and our correspondent states that his figure has been since reduced to 26 cents. We suppose that is the fact in many, perhaps the majority of cases (?) and in the face of low prices already prevailing and the prospects of over-production and its results, no legitimate effort should be spared still further to economize. In that direction and in the pushing of our teas in open markets and introducing them into others practically closed or only partially open, our hope of continued success as tea producers lies. The limits of production with our favourable conditions of soil and climate, have expanded and are expanding wonderfully.

NOTES FROM PEERMAAD.

Oct., 1891.—In the "good old days," September was always the pleasantest and brightest month of the year, but of late years we have been rather unfortunate in having a succession of wet Septembers; this year, however, we have been favoured with the most lovely weather, bright hot days as a rule, with just an occasional shower, every now and again, towards evening. But the sun was what was wanted for the coffee, and we got it, and are happy. Leaf disease, which had shown itself a bit here and there, and of which I wrote somewhat doubtfully in my last, has almost entirely disappeared, and although the crop has suffered slightly on one or two estates, there is now no cause of anxiety, and estimates will be realised. Picking has already commenced in the Periar Valley, and will be in full swing by the end of the month; crops generally on the higher estates being not so forward.

The rapid fall in the Coffee Market is, on the face of it, somewhat disheartening, but it is satisfactory to note that fine plantation is in good demand, and I shall be much surprised if there is not a good recovery in prices long before this season's crop is shipped. By the way, what a ghastly tale of disappointed hopes is told by Messrs. Alston Low & Co.'s Annual Statement of Exports of Coffee from the Malabar Coast during last season! The three ports, Cochin, Quilon and Alleppey, which ship by far the greater portion of the coffee grown in Travancore and Cochin, show only 1,230 cwt. as having been exported. Verily a ghastly record. I am sorry I have not in hand a statement of the export of tea from the same three ports for the same period, as it would have been satisfactory to have had this as a "set off." I most endeavour to send you this with my next budget.

The weather for the past six weeks has been simply perfect for tea, and the flushes have been remarkably fine. The fact that, during September, over 6,000 lb. of tea were made from 40 acres on one estate i. e., 150 lb. of made tea per acre for the month, speaks for itself. A friend who has lately returned from a visit to some of the tea estates in the Periar Valley, reports the tea as looking "simply magnificent," and the Manager of one of the largest properties there, anticipates a yield in the near future of 1,000 lb. per acre. I hope next week to take a run down to the valley and shall be able to send you full accounts of what was—alas that I should have to write it in the past tense—the coffee district of Travancore, and that now promises to become one of the finest tea districts in the country. Nor is this to be wondered at, possessing as it does, a most forcing climate and a soil that is just about perfect. Coffee used to

yield 10 to 15 cwt. per acre in "the Seventies," and if only shade trees had been grown there, leaf disease would undoubtedly have been less disastrous, and but little would, I fancy, now be heard of tea in the Periar, which, in my humble opinion is *par excellence* the beau ideal of a coffee district. The only estate that has attempted anything in the way of shade is still very much to the fore, and though unfortunate in losing its final blossom in February last, has a very nice crop on now and is, I am glad to hear, looking particularly well and capable of giving a still heavier crop in the coming year. As another instance of the productiveness of the soil, I may mention that I once sowed four acres of land with paddy, and reaped 280 bushels, or an average outturn of 70 bushels per acre, a yield which will I fancy bear favourable comparison with the yields of some of the finest corn-producing districts in the world. I must here mention, to avoid misconception, that apart from the natural regard—nay affection—that the pioneer of a district may fairly retain for his "first love," this praise of the Periar is perfectly disinterested; for the writer has long ago parted with the many broad acres he once possessed in the valley, and migrated to a healthier, if somewhat less productive, part of the district.

A forest land in the near neighbourhood of Peermaad has become scarce, and as the demand for land for Tea cultivation is increasing, applications have lately been made for certain blocks of selected grass land, and during the past monsoon, one new grass-land clearing has been planted up, the result of which will be watched with considerable interest, as should the experiment turn out the success that there is every reason to anticipate for it, there will undoubtedly be a large demand for land of this description, of which there are thousands of acres available.

Apropos of this, I am reminded of a remark made by the late Rajah Sir T. Madava Row, when Dewan of Travancore, in reply to an application for a grant of 2 acres of grass-land for every acre of forest held by planters in the Peermaad District, which I had been deputed to make personally. It was urged that it was absolutely necessary for us to secure for each estate a certain amount of grass-land for grazing purposes, as we were alive to the fact that manuring would have to be resorted to at an early date, that there were thousands of acres available, and that the grass-land was utterly valueless except for grazing, and that we paid a heavy tax on our forest land and so on. After a patient hearing, and expressing his pleasure at finding that we were, at that early stage of the Coffee enterprise in the country, turning our attention to the matter of high cultivation, the Dewan, after assigning various reasons for refusing to grant our request, concluded by saying, "And besides this, how are we to know Mr. — that the planters of, say, five and twenty years hence, may not, so far from characterising your grass-land as 'utterly valueless' find it highly suitable for some other cultivation? Tea for instance."

Prophetic words, that may ere long be fulfilled. That the soil of the *generality* of grass-land will hardly bear comparison with that of virgin forests, goes without saying, but, with our great facilities for cheap manuring, and in consideration of the difference in initial cost of land, this need not be regarded in the light of a drawback.

That we are fortunate as regards cheap manuring may be gathered from what follows.

Large herds of cattle are brought up every year from the Cumbam Valley (which literally swarms with cattle and periodically suffers from a felder famine), to graze, and the Travancore Government levies a small grazing fee of 3 annas per head for the season, usually about four months, from February to June. Every estate, however, of 100 acres and upward, is allowed 500 head of cattle *free* and by payment of the above-mentioned fee of 3 annas per head, as many more cattle as may be required can be obtained, without any difficulty, by merely making the necessary arrangements with the cattle owners. Any quantity of manure is thus easily obtained and, as may be seen at a glance, at a ridiculously low cost.

We are great believers in cattle manure in this district, and when supplemented with, for Coffee, a judicious admixture of bones, the most satisfactory results have been obtained. There is hardly a so-called "chemical manure" known to planters that has not been tried. Phosphates, Kainit, Guano, Fish, Peonac, & Co., & Co., have all had a trial, but nothing has ever come up to cattle manure and bones. After all, as they say in Norfolk, "There's nothing like *muck*."

The North-East Monsoon has fairly set in, during the last few days the wind has veered round to the N.-E., and besides having occasional sensations of what is known as "Land Wind," we are having heavy showers in the afternoons, accompanied by thunder and lightning. I hear too that good rain has fallen in Pandy, where, from all accounts, it was terribly needed, as the distress, which has been very severe for some months in the Oumbum Valley, had well nigh culminated in famine. There has been quite a rush of Pandy carts across the hills, in quest of paddy, as the hill harvest on the ghats and neighbouring hills is now in full swing, and prices at this season of the year are ordinarily low. I hear, however, that the cultivators are disinclined to part with their grain, and in consequence of this unusual demand from British territory, are combined to raise prices, and are likely to realise, on what has been rather a poor crop, larger profits than under ordinary circumstances, they would have obtained from a 16-anna crop. Verily it is an ill wind that blows nobody any good.—*Madras Times*.

[We can easily understand that no manure can excel a combination of cattle manure and bones, where both are plentiful and cheap and where the cattle manure is within easy distance of the fields to which it is to be applied. The cost of cartage and carriage on coolies' heads of this bulky and heavy material is, in many cases, prohibitive.—*Ed. T. A.*]

INDIA AT THE WORLD'S FAIR.

An unusual opportunity for advertising Indian goods and manufactures in an effective manner is, says the London Correspondent of the *Pioneer*, likely to be furnished by the coming World's Fair at Chicago, of which so much has already been heard.

It is satisfactory to be able to state that steps have already been taken towards arranging for the adequate representation of British India at Chicago. Early in the present year, Mr. H. Ballantine, Consul for the United States at Bombay, was summoned by his Government to America, in order that he might give his advice as to the best way of securing the co-operation of the Indian authorities and of Indian manufacturers of every kind. No better selection could have been made, for Mr. Ballantine, born in the Land of Regrets, has spent his life in acquainting himself with native languages, customs, and modes of thought, not to mention his large commercial experience. Before leaving the States, Mr. Ballantine was instructed to visit Chicago as Commissioner for India in connection with the exhibition, and in the future capital of the West he conferred with the directors of the show, afterwards leaving for London on his way back to the East, to start his mission. Deeming that some forecast of the probabilities of India being placed well in evidence at Chicago might not be devoid of interest, I paid Mr. Ballantine a visit at his temporary office in Queen Victoria-street on the eve of his departure for Bombay. He was evidently in good spirits at the prospects of the exhibition, and spoke enthusiastically.

"For what class of exhibits do you consider there will be the best opening?" was my next question.

"Well, you may say that there will be a capital opportunity for the Indian and Ceylon tea-growers to make their wares better known," my informant replied. "As I have just been explaining to one of the largest tea houses here, is quite free. But one thing should be remembered—the tea must be quite genuine. Thus far the Indian and Ceylon teas, sold in America, have been pushed on to the market with a blending of Chinese tea, whereas I think Indian teas so good that they can stand entirely on their own merits, Ceylon has

already voted a large sum of money to secure proper representation at the fair, and no doubt the Indian tea planters, when approached, will do the same."

"With regard to raw materials," Mr. Ballantine pursued, "these, too, are more or less free, and so far from the McKinley Bill doing any harm in this direction it has actually modified the duties, where existing. There is no market in the world, I believe, that will be found to pay so well as that of the United States. Oriental fabrics are getting more and more popular on the other side of the Atlantic. Instead of carpets being spread down in the houses of the well-to-do, the tendency now is to go in for Oriental rugs. That has been a great feature of the carpet trade, in which India justly occupies a very high position. Why, look at her capabilities of producing rugs which I claim today are the wonder and beauty of that class of goods, as the beautiful samples in South Kensington Museum will prove! With regard to art work, I consider the so-called pictures of India rather faulty in perspective, but the miniature paintings on ivory are very fine. There would be a large demand in America for this class of goods, if they could be obtained.—*Times of India*.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA COMPANIES AS INVESTMENTS.—In the course of an article on the position of Indian tea companies as shown in Mr. Barnshaw's list to which we recently referred, the *Financial Times* says:—"It would be safe to say that no class of industrial investments has shown such uniformly good results as the Indian tea companies. We leave out of account those with their head-quarters in Calcutta, although by including them the case would be strengthened, some of them having yielded continuous dividends on a generous scale. But, taking the list of twenty-seven companies registered in London, which are included in a comparative table, compiled by Mr. Henry Barnshaw, secretary of the Jokai Tea Company, we find there are only three non-dividend paying companies, of which one is the Land Mortgage Bank of India, presumably holding tea-gardens which have been foreclosed on. Mr. Barnshaw's list leaves out some of the smaller concerns, which are to be found in that published by Mr. George Seton, an indefatigable statistician of the Indian tea industry, who is doing his utmost to attract public attention to the excellent opportunities for investment offered by these companies. Mr. Seton gives particulars of thirty-three separate properties known in this market, of which only two failed to pay dividends in 1890. Taking the two sets together, we find details of thirty-six companies, of which only five, though showing credit balances, were unable to declare dividends last year. As those declared ranged from 3 to 20 per cent., and as the average was not far short of 9 per cent., there can be no denial of the claim that our class of industrial investments shows more uniformly good results.

INVESTORS SHOULD NOTE.—"Objection," says the writer in the *Financial Times*, "might be taken to the use of the word uniform in connection with three dozen companies whose dividends range from three to twenty per cent., but if we restrict ourselves to those companies which recommend themselves most readily to investors as having the advantage of an official quotation in London, we find an exceedingly satisfactory regularity in the rate of the dividends paid. Most prominent of these is the Jokai (Assam) Tea Company, which though it has never approached the twenty per cent. paid last year by the Brahmputra, is entitled in every respect to rank as the premier Indian tea company known in London. Year after year it pays ten per cent with unvarying regularity on its capital of £200,000. The capital value of the estate is only £38 10s per acre, and the shareholders' profit per mature acre last year was £6 16s, or nearly sixteen per cent. The Lebong, quoted in London, and paying six per cent for some years back, is in the exceptional position of possessing a sum equal to more than a third of the capital in reserve, but this proceeded from

sales of property, and is used now to bring new acreage into cultivation. The Assam Company, whose dividends in the past four years have been nine and a-quarter per cent on the average, the last two being ten, has twenty per cent of its capital in reserve, but of the others quoted in London none beats the Joka in this respect."

THE RETURNS.—"Few investments of such regularity in the past and such promise for the future as the Joka Tea Company," the writer goes on to say, "can be brought to yield £8 13s 4d per cent, yet their £10 shares changed hands this week at £15. Assam shares yield £6 9s at present prices. Darjeeling £5 14s 3d, Jorehaut £6 5s, and Lebong £6 per cent, the average dividends in the past four years in these cases being 9½, 6½, 11½ and 6½ per cent. Thus nearly all the leading tea shares on the London market can be bought to return over 6 per cent per annum. Of course the industry is one exposed to considerable risks, both from meteorological and economic causes, but the point that must be insisted on is that, through admirable management both in India and at home, and through the establishment of reserves, these vicissitudes have been robbed of most of their influence on dividends. Hence, for those who desire 6½ per cent industrial investments—in companies whose administration is beyond suspicion, and whose position may very easily be seen at a glance through the medium of such tables as Mr. Harshaw's and Mr. Soton's—there is nothing better in the list than the Indian tea companies."

LAST WEEK'S TEA MARKET.—The *Produce Markets' Review* says:—"The demand for the Indian continues active, the moderate prices having stimulated the consumption and a large business has been transacted. The changes in values have been unimportant, except for the common and undesirable grades, which are slightly cheaper, and difficult of sale even at the lower quotations. The good medium teas, on the other hand, have been keenly sought after, especially Pekoes, which continue moderate in price, and so long as they can be obtained at present rates an increasing use of them may be expected. Pekoo Soucheongs of good quality and giving a strong, brisk infusion have sold readily at previous values, and as the supply of these will probably not exceed the demand, the present level of prices appears safe for holding a good working stock. The finest descriptions, which are not so liberally represented in the later arrivals, continue to meet with a good reception at steady rates, while any breaks with exceptional quality command extreme prices. At the public sales 38,190 packages were brought forward, and mostly sold at firm to steady prices for all excepting the commonest kinds, which were easier. The late rise in prices of Ceylon teas has rather diminished the demand, and as the quantity offered at the sales this week has been somewhat larger, competition has been rather less keen, and prices in some cases are slightly easier. The quality of the teas still maintains the late improvement, and the greater care in cultivation and manufacture accounts for the fact that many gardeos now easily obtain 1s per lb. against about the 8½d to 9d procured with difficulty in July." At the moment the statistical position is improving, as the imports for this month will undoubtedly be very small, and the end of October will in all probability see the stock reduced to 15,000,000 lb. Of Indian teas the *Grocer* says:—"The market this week has been almost overdone with supplies, which have aggregated 38,300 packages, and have caused continued languor to prevail. The samples, as may be imagined, have been so multifarious that tastings of the entire offerings have been physically impossible by a single valuer for a series or set of sales by auction, and several invoices have been passed over as not suitable to the existing demand. This accounts for the frequency with which many lots were retired in silence as the auctions progressed, and when the only bids elicited were much below the valuations. As it

was, all undesirable and thin ligoring sorts were realised without spirit at barely previous rates—low pekoes down to 6d per lb.—and a feeling of inertia was plainly evident in most of the biddings that were made. Teas with quality alone engaged attention deserving the name, and these were chiefly taken off at full prices.

BRAZIL COFFEE PROSPECTS.—Messrs. C. J. Leach & Co., in their weekly circular, say:—"The increase in the world's visible supply, amounting to 25,000 tons, or, roughly speaking, 450,000 bags, during one month means that the stock will soon be considerably augmented, and with three more months of Brazil receipts on a magnitude equal to those of September, the famine period will have passed away altogether. Notwithstanding the heavy shipments, stocks in Brazil ports are increasing fast, and the extraordinary course of the exchange this season is totally against any holding power on the part of the Brazilians. It is, therefore, of paramount importance to watch the course of receipts and exchange. So far only some 1,500,000 bags of the crop have been disposed of, leaving still 6,500,000 bags to find a market. A recovery in the exchange would go far to stem the declining tendency, but if, as we hear, the weakness in exchange is owing to fear of a further issue of paper money, there would appear to be little hope of a permanent recovery. In our circular of May 8th last we mentioned that a decline in the exchange to 15 was quite possible. This week it has been as low as 14½, but closes at 15 again." Messrs. Norton, Megaw, and Co. cable that flowering is good in Rio and Santos. Messrs. John Bradshaw and Co., of Rio, cable:—"Coming crop reported in a favourable condition. Blossom indicates a large crop." Messrs. C. W. Gross and Co., of Rio, cable:—"The September flowering is almost nil; that of October promises well." Messrs. Holworthy, Ellis, and Co., of Santos, cable:—"flowering good." Messrs. Gustav, Frinks, and Co., of Rio, cable:—"Flowering irregular; expect moderate crop—perhaps 3,000,000 bags." Messrs. Wilton, Smithett, and Co., in their circular of the 13th inst., says:—"Notwithstanding the moderate available supplies of this article as compared with former years, the heavy decline reported in our last, has as yet received little check. The trade are unwilling buyers, as they hold a fair supply at a much higher range of price, and can only with difficulty effect sales. At the same time the lower level now reached renders the position more stable, and with a return of confidence, some reaction seems inevitable. The fortnight's supply in auction was extremely moderate, and consisted mainly of Guatemalan and Colombian. These met lower offers, but as importers, as a rule, were willing sellers, a fair proportion changed hands at a decline of 2s to 4s from previous prices. Undesirable lots of various growths in second hands were sold "without reserve" at very low rates. Very heavy fluctuations have again taken place in the speculative markets, and quotations have fallen considerably, near months folly 5s; December delivery was quoted at 4s. 6d at one time, but a rise in values is established, at the close, based on rumours disadvantageous to the blossoming of the next Brazil crops. The latest auctions also showed signs of greater steadiness and prices rather above valuations were obtained. Rio and Santos shipments for the first three months of the season amount to:—1891, 88,440 tons; 1890, 71,040; 1889, 56,990; 1888, 81,180; 1887, 24,460; 1886, 84,730.—H. and C. Mail.

NEDUN AS A CABINET TIMBER.—To show how high in quality this timber is we may mention a circumstance within our knowledge. The occupants of a bungalow open-air received a present of a mirror, handsomely framed in dark walnut, which they placed above their drawing room fireplace. A friend gave them a design for a handsome chimney piece to form a base for the mirror. This was made of nedun, which, polished and varnished, cannot be distinguished from the walnut unless close attention is invited.

* The real reason was improved meteorological conditions, leading to less-luxuriant flushing and better ability to wither the leaf properly.—Ed. T. A.

TEA at tea-time may be grateful and comforting but tea at luncheon-time or dinner-time is a delusion and a snare. Such is the sermon which the oditor of *Woman* preaches to the gentler and more tea-drinking sex. Even as Mr. Rudyard Kipling holds up one of his heroines to scorn for living on "tea and pickles," so this stern monitor of the fair asserts that "there is a disjunct want of character and dignity about a lot of women seated at marble tables, munching dyspepsia-provoking plum-cake, and sipping equally unwholesome and more unpalatable tea from thick white bowls, facetiously styled teacups." He adds that, "In these days, when women have to think and act for themselves, they must fortify their constitutions," a purpose clearly difficult of attainment by means of bath buns and scones. After this eloquent denunciation of these staple articles of feminine diet it seems almost like an anti-climax to read that "It is not necessary that a woman should eat a big rump-steak, or drink a bottle of claret or a tankard of ale in the middle of the day."—*Daily Graphic*, Oct. 15.

AN EXHIBIT FOR THE "WORLD'S FAIR," CHICAGO.—The Forestry Division of the United States is preparing an exhibit for the Columbian Exposition—or "World's Fair"—at Chicago, in 1893, and will endeavour to obtain models or samples of the different forms of metal ties—sleepers—which are in actual use, in order to show, what is not very generally understood, that the question of the use of metal track is no longer an experimental one in other countries. Apart from minor experiments, two systems are now being given careful trial—the Hartford steel tie on the New York Central and Hudson River Railroad, and the Standard steel tie on the Delaware and Hudson Railroad, the Philadelphia and Reading Railroad, and the Chicago and Western Indiana Railroad. The former is an inverted trough, with a groove along the top, and having the ends curved down. The latter is a channel with the open side uppermost, the bottom cut away at the middle and bent upwards, and a block of compressed wood under each rail. Both have bolt fastenings. A third system, the Morrill steel tie, somewhat similar to the Standard, is to be tried on two roads.—*Indian Engineer*.

TEA AND COFFEE IMPORTS AT AMSTERDAM.—Consul Robinson reports upon the Trade and Navigation of the Port of Amsterdam during the year 1890 as follows:—*Coffee*.—The total importation of coffee in 1890 was slightly larger than in the previous year, although the entire failure of the Java crop caused a great deficiency in the shipments from the Dutch East Indies. This was, however, made up for by an increased supply of other descriptions, principally of Santos, the importation of which was nearly double that of 1889. The price of Java coffee rose, with some fluctuation, from 9½d per lb. in January to 10½d per lb. in November, closing end of December at 10d per lb. The production of Government coffee in Java showed a most remarkable decrease since 1881, when the quantity offered for sale through the Netherlands Trading Company was 913,881 bags, dwindling to 416,490 bags in 1890; the 1891 crop will probably not exceed 350,000 bales. Speculative transactions were limited, and the Amsterdam clearing office reports a turn over of 978,500 bales (762,500 Santos, and 216,000 Java), as compared with 1,150,260 bales in 1889. *Tea*.—Chinese tea continues gradually to disappear from our market, the total importation being 5,293 quarter chests, as compared with 9,938 in 1889. The quality of the importations gave general dissatisfaction. The consumption of Java tea, and especially of the Assam sorts grown in Java continues to increase. Prices, especially of the better sorts, improved somewhat during the year.—*L. and C. Express*.

OF THE JAVA COFFEE CROP estimated at 380,596 pikuls; 374,559 pikuls have been received at the Government local storehouses and 35,629 pikuls have reached the shipping ports.—*S. F. Press*, Oct. 29th.

COCONUT PLANTING IN THURSDAY ISLAND.—The *Torres Straits Pilot* of 3rd Oct. says:—

Mr. Armitage, the gentleman who is engaged by the Queensland Government to plant coconut trees, has arrived. He will probably make a cruise in the cutter "Lizzie Jardine," during which he will plant many hundred young coconuts on the islands in Torres Straits. The trees in future years will prove of great value, especially in these waters; and it is sincerely hoped the majority of them will thrive well.

PEROCARPUS INDICUS.—In the extract you published the other day about the timber from this tree, reference was made to its fine dark color. I have several pieces of furniture some years old made from one of the trees which grew in Slave Island, and it is a very light color and does not turn so dark as satinwood with age. It is a beautiful close-grained wood and takes a good polish.—*Cor.* [It is possible that, as in the case of many other trees, the root portion of the tree may be dark-coloured?—Ed. T. A.]

FIT FOR EDEN.—Among cultivated fruit, one stands as yet unrivalled for its beauty, aroma, and delicious flavour. Singularly enough, however, not even Her Majesty, though Empress of the vast realm in which it is grown, has tasted it. Imagine a huge laurel, with leaves somewhat narrow, blossoms like a single rose, and lemon-shaped fruit of the colour of a ripe apricot—a rosy hue apparent through the primrose and gold. The flesh is rose-coloured. So delicious is it—such subtle commingling of refreshing juices, subacid and sweet, that even the dying will eat it greedily—one can see, as old Anglo-Indians speak of it, that even the reminiscence is a pleasure, making the mouth water. Such is a brief description of the *Marysteen* or *Maryostana*.* Only twice has it been fruited, in a strong moist heat, in England—once at Sion House, the Duke of Northumberland's, and about 1865 at Hooley Hill, near Croodon by Mr. Mundell, of Moorpark Gardens.

JAFFNA TOBACCO AND THE GOVERNMENT OF TRAVANCORE.—The "Hind Organ" states that the Government of the Native State of Travancore "has promulgated a new Order, if not with the view of driving away the Jaffna tobacco from the Travancore market, certainly, with the object of specially encouraging the consumption of the Coimbatore tobacco in that State. By virtue of the Order in question Coimbatore tobacco can now be sold in all parts of Travancore, paying a duty of only R30 per Candy, competing with the Jaffna product still subject to the levy of R90 per Candy. To all outward appearance, we are informed, the duty on both kinds of tobacco is still the same, but practically the one kind of tobacco is made to compete with the other with a difference of R60 in the Government duty." "Intelligence has been received here from Travancore that the quantity of Jaffna tobacco sold in the several Government Bakhshs there have been monthly decreasing, since the new Order has come into force, although sold at a considerably low price to keep pace with its rival. Great depression consequently prevails in the Jaffna-Travancore tobacco trade." "We have before us copy of a respectful but earnest and closely reasoned memorial addressed to His Highness, the Maharajah of Travancore, by the merchants of Jaffna, pointing out the injustice and impolicy of encouraging the tobacco of one country at the expense of that of another, which had been both for a century or so, treated with equal favour; and praying that the new order complained of may be rescinded."

* Misprints, of course, for 'Mangosteen' and 'Mangostana.' The description of the fruit, however, does not accord with fact.—Ed. T. A.

FOREST CONSERVANCY.

This is Mr. Broun's first report as head of the Forest Department, that is to say he has written it as Acting Conservator of Forests, his appointment requiring of course the confirmation of the Secretary of State, which may be taken for granted. But the report refers to a year when Mr. Broun was still only Deputy Conservator, for, when Colonel Clarke was compelled to go on sick leave, Mr. Broun was absent in India, and Capt. Walker as Senior Assistant Conservator, acted as Conservator for just the last week of 1890 Mr. Broun returning on 31st December. As a trained professional man, Mr. Broun writes a very detailed and elaborate report, which is largely occupied with imperfections of departmental organization, procedure, departmental rules and forest laws. The amendment of the latter, it seems, is delayed until the appearance of a new edition of the Indian Forest Act, which will, of course, embody the results of the latest and most extended experience of the multitudinous details of forestry and their bearing on the interests of agriculturists specially, and the community in general. At the commencement Mr. Broun very properly expresses his regret that the Government rules as regards half-pay for acting appointments could not be relaxed in the case of Col. Clarke, who certainly contracted the fever which has affected him so seriously when engaged in duties connected with the Forest Department. Like every other head of a department Mr. Broun wants more money than Government is willing or able to grant; and with much reason, a plea is put in for the forest officers, that, subjected as they are to special exposure, they should not only receive better pay; but, as regards pensions, be put on an equal footing with the members of the P. W. D. A protest is entered against the humiliating rule that a forest officer cannot cut a stick of wood without the permission of the Government Agent. We can understand due powers being reserved to administrative officers, but surely this is compatible with vesting forest officers with discretion such as native roadmen exercise. Mr. Huddleston was employed during a portion of the past year in reporting on the forest resources of the Trincomalee district, and his initiatory report gives a striking impression of the devastating results of the system, or rather utter absence of system, which prevailed about forty years ago, when, without any adequate return to Government, there was a continuous export from Trincomalee, for years in succession, of valuable ebony, satinwood, balmilla and other timbers of which the Government forests were denuded for the advantage of individual traders. In regard to a large portion of those eastern forests, the attention of the forest officers must for many years be devoted to the not immediately profitable but absolutely necessary work of encouraging by every possible means the process of natural reproduction: letting the light have access to the seeds which are plentifully distributed in the soil and preventing the access of destructive animals and fires, as well as destructive natives who never hesitate to cut down saplings of the finest species of timber trees for fence sticks and similar uses. In one part of the report it is stated that valuable

saplings are recklessly cut by the natives, not only for their own use but for sale to Indian dealers! The remedy of course is to demarcate and set apart village forests for supplies of timber and ehena cultivation. That once done, trespassers on Government forests and forest reserves ought to be rigorously prosecuted. Mr. Broun complains of the slowness of the processes of survey and demarcation of boundaries, and protests against forest surveys being complicated, as in Sabaragamuwa, with the settlement of village claims. Mr. Broun also very properly insists on the forest officers qualifying themselves to execute surveys of a nature from slight sketches to more elaborate plans. A fully qualified forest officer, indeed, must be a man of great and varied accomplishments; a botanist with a keen eye for peculiarities of soil and climate, a judge of the qualities of growing timber and an adept in its treatment when growing and after felling, a competent surveyor and well acquainted with native languages and customs,—especially the communal laws. How valuable the knowledge acquired by experience can be is illustrated by the history of *patu* timber for railway sleeper purposes. This timber has been rejected because of cracks, the result of felling when green, but an experiment in ringing the trees and leaving them standing for a year subsequently has obviated this difficulty. We are glad to notice that teak at Puttalam and mahogany at Jaffna have been fully successful; and it is quite clear that the latter, the most valuable perhaps of cabinet and structural timbers, should be extensively cultivated in the dry and arid regions of Ceylon. If in 1843 a hundred thousand mahogany trees, instead of four, had been successfully planted at Jaffna, the timber would now or a few years hence realize large wealth for the colony. From measurements given of trees planted at different periods between 1843 and 1885, we learn that the mean girth at breast height of 4 trees planted in 1843 is 8 feet 7 inches, or 103 inches—which means a diameter of over 34 inches,—the mean annual girth increment having been 2.19 inches. It is quite evident that special attention should be devoted to teak and mahogany, amongst exotic timbers in the lowcountry as well as to the Australian *eucalypti* and *acacias* and to the Himalayan cedars and pines, in the higher and wetter regions. There is another valuable timber tree, which has made itself at home in Ceylon from Colombo up to Peradeniya. This is the *padouk* of Burma and the Andamans, which, as a paragraph we recently quoted proved, has excited much attention in Britain, from the strength and beauty of a specimen sent from the Andamans. So long ago as 1843, the late Mr. William Ferguson attracted attention to the magnificent specimens of this tree,—botanically *Pterocarpus indicus*,—growing near what was then the Cayton Rifles mess-house, and which is now the property of the Ceylon Commercial Company. The handsome umbrageous foliage of this tree is occasionally contrasted with a wealth of golden blossom rich with delicious perfume. The cultivation of this valuable and beautiful tree ought certainly to be extended, and sandalwood ought to be tried in the Puttalam district and other portions of the island. But why has the Forest Department neglected that near relative of the mahogany, but which unlike that tree flourishes at 6,000 feet and over, the timber of which is by many deemed quite equal to mahogany,—the cedar of Australia, the red toon: *Cedrela Toona* var. *serrata*. The grove of these trees near the Lake bund at Nuwara Eliya is conclusive as to their suitability for cultivation at high altitudes even if experience at Darjiling and other Hima-

layan stations were not sufficient. For railway sleepers the red *dun* (not only native but peculiar to Ceylon) is the favourite; but other timbers are being tried; and, with Col. Clarke we believe strongly in the value of the ubiquitous and often gigantic *kumbuk*. Mr. Brown states:—

Instructions were sent to the following Provinces to saw 200 experimental sleepers of each of the following kinds:—

W. PROVINCE.—Alubo, etahoribelliya, bakmi, and dawata.

E. PROVINCE.—Tumpalni, ken, naval, palai, chemelpaniche, kokatiya.

N.-W. PROVINCE.—Timbiri, kirikon, tammana, godapara.

Amongst these and others, we cannot doubt that excellent wood for railway and other purposes can be found.

The famous ebony of Ceylon being a purely cabinet or ornamental wood, it may be interesting to notice the proportion in which other timbers are in demand; satinwood, which is both a cabinet and a structural wood and others which are wholly or almost wholly devoted to useful purposes as distinguished from ornamental. Until recently the run, both for home use and for export has been on Halmilla, Satinwood, Palu or Pallai, Milla, Na, Rani or Woweranai, Dun, and a few others. But the value of other timbers, such as Kumbuk, Alubo, Dawata, Kon, Tammana, Gedapara, &c., is gradually being appreciated. The proportionate demand indicated in the felling operations of the Forest Department in 1890, is thus shown:—

VERNACULAR AND POPULAR NAMES.	NUMBER OF TREES FELLED.	VERNACULAR AND POPULAR NAMES.	NUMBER OF TREES FELLED.
Halmilla ...	4,510	Hora ...	69
Satin-wood ...	2,948	Mar'osa and Hulambik (both allied to the Teon) ...	58
Palu or Palu ...	1,712	Nadu and Ubrilya (cabinet woods) ...	52
Milla ...	1,927	Jak ...	41
Na (iron wood) ...	619	Pihimbiya ...	30
Ranai or Woweranai ...	562	Mihiriya ...	25
Dun ...	462	Hal ...	20
Mendona and Tum-palai ...	418	Mi and Wanami ...	17
Kina and Domba ...	324	Other species ...	2,253
Kumbuk ...	281		
Domba and Naval, (the latter the Mahadan of the Sinhalese) ...	147	Total ...	15,846
Ebony ...	144		

of which 8,292 were dry and 7,394 green trees.

Our readers will, of course, note that the above figures refer only to legitimate fellings by the forest officers. Illicit fellings and felling of trees on private properties are left out of view, and we should suppose a good deal of the original and coppice growths cut for fuel, both in Government and private forests. Far more jak and some other trees grown around native houses or in private or village ehenas are utilized than the quantities shown by the forest department. The palmira trees cut down, chiefly for export to

* On an unjustifiably extravagant use or rather misuse of the fine cabinet wood *nedun*, we quote a paragraph from Mr. Brown's report:—"At Kainapura a new pest office, the design of Mr. Spooner, is being built entirely of *nedun* timber. It seems to be a great pity to use *nedun*, which is a most valuable cabinet wood and is daily becoming scarce." The question is who sanctioned Mr. Spooner's expensive whim? The two together ought to be made to pay the difference between the cost of *nedun* and good ordinary timber.—Mr. Brown's remark that *nedun* is becoming scarce reminds us that "estamander" wood (*kalu-mediya*), a near relative of ebony but much more beautiful is almost extinct. Ought not nurseries and plantations of such valuable trees to be formed?

India, as rafters and reapers, must be almost exclusively from private property, and we are greatly concerned to find Mr. Brown contemplating the gradual extinction of this most valuable timber, without indicating that the forest department intends to make any special effort to prevent what would be a real loss to the Colony and a most serious misfortune to the poor people of the Northern Province whose livelihood so largely depends on the varied and valuable products of the palmira palm. The export of palmira laths and rafters seems to be diminishing, not because the people have become more alive to the duty of preserving the trees as food yielders, but because continued felling without corresponding planting has rendered suitable trees scarce. The export figures for 1889 and 1890 were:

1889 Palmira laths and rafters ...	296,484
1890 do do ...	263,090
Decrease	33,394

We suppose the new industry of preparing fibres from the leaves may in some measure compensate for the falling-off, but the whole question of palmira culture deserves the most earnest attention of the forest department and of the administrative officers of the northern and drier portions of the island. A communication we recently published showed that the jungles in the portions of the Jaffna Peninsula adjoining the "meinland," and perhaps well into the mainland, are full of palmira plants, which only require the clearing away of useless growths, such as inferior thorny acacias, and the admission of light and air, to flourish. Mr. Brown dwells on the usefulness of a timber which has been found to last ten years. There are palmira rafters and reapers in houses at Jaffna and elsewhere, built in the Dutch time, which are known to be considerably more than a century old and which are still unaffected by decay. We submit that the conservation and propagation of a tree so valuable as a sugar, fruit, root, and fibre yielder, and which at maturity yields a building material which cannot be surpassed, deserves immediate and most serious attention. It is unfortunate that in the Customs accounts only a few of the timbers exported are distinguished by their names. In 1890, no fewer than 4,208 packages, 7,781 logs and 928,403 "number" are lumped up as "woods of sorts." As this is an important and increasing branch of our commerce, we submit that the time has come when the "woods of sorts" should be sorted and tabulated by their vernacular or popular names. The natives generally know these, and should the Customs officers experience any difficulty, they can readily obtain aid in identification from the forest department, in connection with which a herbarium and museum of timber specimens has made good progress. "Timber dye-wood and rosi," of which 10 packages and 1,436 cwt. were exported in 1890, must have been nearly all sappan wood, and yet sappan wood is given separately at 2,774 cwt. and 26 packages. Of ebony the exports last year were 9,709 cwt. The exports are chiefly to China; and our readers may recollect that Col. Clarke restricted sales in order to raise the market price to a remunerative rate. Mr. Brown recommends the felling and sale of a moderate quantity yearly. Satinwood, the specific gravity of which is not much under that of ebony, is, like that wood, recorded by weight, the quantity exported in 1890 being 306 cwt., 2,179 logs and 58 "number." Of ironwood 656 logs and 81 "number" were sent away. Of our best and most generally

useful timber, halmula, (valued in India for gun carriages and similar purposes) 1,651 logs were exported. Pieces of oak to the "number" of 8,300 are included in the exports. Of coconut laths and rafters 100 packages and 2,257 "number" were entered for export, with laths and rafters of timbers not described 7,158 packages and 1,593 "number." Finally we have the "ridiculus mus" of 9 kitul laths and rafters. As our forests are demarcated, reserved and scientifically treated, being permeated by roads and paths to facilitate not only inspection but the easy transit of timber divided into logs, deals and scantlings by means of steam saws, there will be supplies of good timber and fuel, sufficient for all local wants and export demands, which are certain to expand. Mr. Broun, by the way, anticipates the early ability of his department to meet all the demands of the railway for fuel, leaving private forests available for private demands. This will be good news for householders in our cities and for the owners and workers of plantations and tea factories. And this reminds us of an apparent omission from Mr. Broun's report of any reference to the large and urgent fuel demands of the tea planters and the best means of supplying them. This must be due to inadvertence, equally with the different modes of spelling the name of one of our most valuable forest trees,—*palu* and *palai*. Which is it to be? There are the Tamil names of places, Patchelapallai (the green home of the palm tree?) and Palsi, derived, no doubt, from the tree. Yet the general form in books and reports, of spelling the name of this valuable tree is as certainly *palu*, the Sinhalese form. But as the tree is chiefly prevalent in the Tamil districts, the Tamil name ought to prevail. Mr. Broun, like all his predecessors, protests against the careless and to the tree, as a source of timber, most injurious practice of the natives of breaking the branches of this valuable tree in order to obtain the fruits.

Now that Mr. Broun has become Conservator of Forests, we suppose the office of Deputy Conservator disappears from the list. The establishment then, consisted at the beginning of 1891 of

- 1 Conservator.
- 9 Assistant Conservators.
- 1 Superintendent railway fuel.
- 4 Foresters.
- 4 Probationers at Debra Dua.

The latter have all, we believe, returned to the island; and we suppose there will be a reorganization of the department, in accordance with Mr. Broun's views, which seem to be that an Assistant Conservator for each of the nine Provinces is not required, and that the superior staff can well be reduced and the money saved applied to the provision of better remuneration for the subordinate officers, although large help from the Surveyor-General's Department is gratefully acknowledged. Mr. Broun, like every one else, feels the want of a cadastral survey of the island. If we are to have a land tax in lieu of the grain rent and duties, such a survey will become an urgent necessity; but unless the Survey staff is increased at least four-fold, the work will not have been much more than begun at the end of this century, and will require the next for its completion. The report states:—

Of the surveys undertaken by the Survey Department the most important are those of the proposed railway fuel reserves, near Mrigama and Ambepassa, which are now approaching completion; those of Pallekole in the North-Western Province, Pallewatta and Yagirala in the Kalutara District, and the extension of surveys in Gilimale and the survey of the Kelani Valley in the Province of Sabaragamuwa.

The area of completed surveys amounts this year to 72,153 acres, or nearly 113 square miles, including villages in the Peak wilderness and in Pallekole. This brings the grand total of completed forest surveys to 194,478 acres, or nearly 303.87 miles.

The addition of nearly 113 square miles to the 183 square miles already surveyed is very satisfactory, but still, considering that there are several thousand acres to survey and settle, it does appear as if more extended operations should be taken in hand, otherwise the Forest Department will for long years not be on a settled basis.

Area reserved since 1885.—Forest Settlement Officers have been somewhat more busy during the year under report than before, and a few final Proclamations have been made, chiefly in the Province of Sabaragamuwa, where Bambarabotuwa, Wellankanda, Kaduwalakanatta, Talawitiya, Hunuwala and Huppitiya forests, covering in the aggregate an area of over 22,000 acres, have been finally proclaimed as reserved forests. But much remains to be done, and the Survey Department complains that unless the work of reservation is carried on somewhat quicker the survey lines will soon become obliterated, and much expense will be incurred in making fresh ones. At present the area of reserved forests is as follows:—

	Up to 1890.	During 1890.	Total.
	Acres.	Acres.	Acres.
Central Province	852*	—	852
North-Western Province	132	892	1,024
Province of Uva	710	—	710
Province of Sabaragamuwa	715	22,497†	23,212
Total	2,409	23,389	25,798

Surveys of forests and the reserve of such forests are two very different things, as the report indicates:—

The names of two forests in the Central Province, the preliminary notifications of which appeared in 1890, had already appeared in the *Government Gazette* in 1888, but the forest settlement made by the then Forest Settlement Officer was so little in accordance with instructions laid down in the Forest Ordinance that it was set aside by Government. They are the forests of Kkadapolla, Sita Eliya, and Pedrukunaduoya, near Nuwara Eliya.

The forests in the Province of Sabaragamuwa, the completion of the reservation of which is still being awaited, include certain forests in the Kegalla District and also the Gilimale forest, a block of forest of over 17,000 acres. In the Southern Province the forests of the Matara District urgently require reservation, but although a few preliminary notifications have been issued no further steps have been taken. The proposed reserves in the North-Western Province are in the Obfaw and Puttalam Districts.

In Uva the Government Agent has granted a site in the Hapatale reserved forest to the Hapatale Railway Extension Department for the purpose of building houses for subordinates. According to the Forest Ordinance a proclamation should first have been published in the *Government Gazette* declaring that portion of the forest to be no longer reserved. However, nothing has as yet been done.

The Conservator complains that while the zealous Government Agent of the Province of Sabaragamuwa is obtaining village settlements out of money voted for the Forest Department, the reserve of such valuable blocks of forest as that of Pallekole in the North-Western Province should be delayed. Preliminary notifications of the reserve of 23 forests had been published, without the reserves being finally proclaimed. To quote the report:—

No working plan has as yet been made, but the Nuwara forests were worked on the system mentioned in paragraphs 21 and 22 of the last annual report.

* Includes Campbell's land, reserved under the "Land Resumption Ordinance," but does not include Walapaua which is not yet surveyed.

† Exclusive of Hunuwala forest, not yet surveyed.

As regards the forests set apart for the railway fuel supply between Mirigama and Ambepussa, the surveys, are still being made, but there has been unaccountable delay in starting the chenas. I hear that a block of land, some 200 acres in extent, has been subdivided into a number of plots, and hope that this year at last the work will be taken in hand.

The opening and keeping open of boundaries involves, as may well be supposed, much difficulty, the total length already being no less than 1,180 miles. Mr. Broun desiderates straight boundaries for reserved forests. Enumeration surveys, that is the ascertaining of the numbers of trees of different sizes, &c. in forest areas, are needed. We have already alluded to the disappointing results obtained from a small operation by Mr. Huddleston, and Mr. Broun thus comments on the astonishing figures:—

If the enumerations are a good sample of the Trincomalee forests, these are extremely poor, for first class trees (second and unbound), which form the majority of the exploitable stock, do not amount to 1-5th tree per acre. In spite of this small number of exploitable trees those of smaller classes are also exceedingly scarce, the number of fourth class poles being most scanty. The report speaks of one or two "favoured nooks," where there is some good stock, obony being found fairly abundantly in one patch, while palai forms an almost gregarious forest about one square mile in extent at a place not far from Kantalai. This shows that the Trincomalee forests have been most severely overworked in former times, and that they should be now dealt with with great care and caution.

Alluding to protection of forests Mr. Broun states:—

Headmen of villages are still supposed to carry out the protective duties over the Government forests. They carry out their work well or fairly well in some places, but on the whole I think that the employment of unpaid headmen as forest police is a mistake, and that paid forest subordinates should gradually replace them as the forests become reserved. From my own experience I can say that I have come across both good and bad, several of the latter having so little knowledge of the forests they were supposed to guard that they had to keep villagers by them to show the way through the forest.

It is somewhat sensational to find the European owners of estates charged with annexing Government forest. The report states:—

One case deserves special mention, being one of considerable encroachment on Crown land by the proprietors of Barra estate near Rakwana. Although the boundary was old and hard to follow, the land had remained in the same hands from the time of purchase from the Crown, and the proprietor could not plead ignorance. After a preliminary inquiry in the Rakwana Court the case was settled by composition, the sum paid being Rs 694. Further encroachments are being made by certain estate proprietors, and there is now one case under report in the Kegalla District which, if proved, deserves severe punishment. It is added:—

Several cases were made very difficult to prove owing to the recent decision of the Supreme Court, that it must be proved that wood removed illicitly has been removed from Crown land. The decision appears to go against the spirit of the Ordinance, for in section 72 it is stated that the onus of the proof lies with the accused. This is not due to an accidental oversight on the part of legislators, who merely followed the example set in Continental Forest and Hunting Laws. In these, owing to the facilities with which an offender can escape on account of the extent of the forest and the sequestered position of the place where the offence has been committed, it has been laid down that the proof lies with the accused.

The prevention of wasteful chena cultivation requires vigilant attention. Direct encouragement, as we noticed, has been given to such cultivation by the abolition of the tax, the paragraph referring

to the matter being as follows:—

The Assistant Conservator, Sabaragamuwa, complains that owing to the abolition of the tax on dry grain a new impetus has been given to chena cultivation, and that this abolition removes the evidence of Crown right to the land, as no tax receipts will in future be issued. He suggests therefore that no land be granted by the Crown for chena cultivation without the cultivator being bound to drain it and to put a boundary drain round it. This would not only preserve the evidence of Government right, but save the land from losing all its top soil. The suggestion of the Assistant Conservator is, I think, a good one, but a land settlement allotting chenas to each village would be much more satisfactory.

Several officers complain that prosecutions against illicit chena cultivation are being far too leniently dealt with by magistrates, and that they and their subordinates are being disheartened by this treatment. There is no doubt that a fine of 50 cents for illicit cutting and burning of Government forest is a farce, and that it would be much better to dismiss a case than to give the accused a distinct encouragement to go and do more damage.

There are interesting details regarding the natural reproduction of forest trees, too long to quote in full. The reference to the Southern Province is, however, of special interest:—

The Assistant Conservator complains of the reckless destruction of young growth by villagers, who cut everything, regardless of species, for fence sticks and for sale to Indian dealers.

That valuable plants should be cut down for fence sticks is bad enough, but to devastate the forests to supply Indian dealers is a matter which requires stringent intervention. Mr. Broun is emphatic in the enunciation of the principle that the proper treatment of existing forest with reference to natural reproduction is the first duty of his department, and not the formation of plantations of exotic or special native trees. He adds:—

Wherever plantations are desirable they should, to my mind, be made of considerable extent. Small plantations should be avoided, excepting for experimental purposes, for the cost of labour, supervisory, and protection is much larger per acre than on a large plantation.

The only plantations of any considerable extent now existing are the teak chenas of the Batticaloa district. These covered at the end of 1889 639 acres; but nothing was added during the year under report owing to the careless way with which grantees treated the plantations under their charge. They have now been ordered to take greater care of the seedlings and to make nurseries to supply vacancies. The Assistant Conservator has sent in a number of measurements taken in the chenas of Tampalanchelai, Divilane, and Palngauwa. The results are interesting, inasmuch as the average girth of the samples measured is as good as that of trees measured in Indian and Burman plantations. Nothing is said, however, as to whether the poles measured belong to the average class or whether they were dominant or suppressed, nor is anything mentioned about the height of the trees nor about the number per acre. This is important as the poles measured may have been standing isolated, and may have become developed in girth and in crown and little in height. It will be noticed (see table, appendix A) that the plants measured show rapid growth up to about four or five years of age, and that they suddenly fall off in mean annual increment. The cause of this is probably the iluk grass which springs up abundantly as soon as the chenas are abandoned. In the case of the Divilane plantations, where the growth appears to be more vigorous, the growth again improves between the eighth and tenth years, probably owing to the formation of leaf canopy and consequent suppression of the grass.

In the Western Province the jak gardens near Mirigama have not yet been extended, but a block of 200 acres has been taken up and divided into plots to be

given up for cultivation and rearing of forest trees with the crops. This matter has been so much delayed that there is great fear of the villagers losing all interest in it.

Only about five acres were added during the year, being land along the bank of the Pussoloya in the Barawa forests. R254 was spent in clearing dead and worthless wood, in cutting it up into firewood, and putting in hat seed. The sale of the firewood will go a long way towards covering the cost of clearing and planting.

In the Central Province the strip clearings were extended, ten more squares being cleared and planted. The plantation of 1889 has been a failure and has had to be practically replanted. On the report of the Assistant Conservator, Central Province, I visited the plantations of 1890 in October last, and found that the work had been most carelessly done, Mr. Armitage having left too much of the supervision to inexperienced subordinates. This year the plants put in were *E. globulus* and *robusta*, *Acacia decurrens*, and *Cryptomeria japonica*. Seeds of *Pinus longifolia*, *Cedrus deodara*, and *Acacia decurrens* were also dibbled in *in situ*, and were reported to have germinated freely. The *cryptomeria* and blue gum plantations behind the Assistant Agent's house are doing well. Blanks were supplied and overhanging branches cut. Sambar and pig are still doing damage by barking and rooting up young trees and trampling on tender seedlings. Near the nursery and by the Public Works Department lines on the Nuwara Eliya and Nannu-oya road small patches of waste land were cleared and planted with *E. globulus* and *robusta*, *Acacia decurrens*, *Fraxina*, and *Cryptomeria*, and seeds put in of *Pinus longifolia* and *deodar*. At the end of the year a large percentage was thriving.

Early in October the Assistant Conservator and I inspected waste lands in the neighbourhood of Gampola, Nawalapitiya, and Galboda, with a view to recommending the reservation of a certain number of them for Railway fuel plantations. Most of the blocks of land were favourably reported upon, and before the end of the year 200 acres of patana grass were cleared and ready for lining. Judging from similar plantations in the hills, it is probable that these will yield from 100 to 150 yards per acre during the next fifteen years, and they will thus not only keep up a regular supply for the Railway, but will more than pay their way. It is very desirable that this land be reserved under the Forest Ordinance, as it is only plantations in reserved forests which obtain the special protection of the law. The definition of the boundaries on the ground is very desirable.

In Uva the young plants on Judge's Hill, at Badulla, are coming on well, especially where the land has been kept free of weeds. The plants put in in December, 1888, are up to nearly twenty feet in height and twelve inches in girth, the average being about twelve to thirteen feet in height and seven to eight inches in girth. The plantation consists of sapu, grovilloa, ingasaman, osuarina, and flamboyants, and all are doing fairly well, but no more flamboyants are to be planted. The plants put in in 1889 are also doing well, being generally about four to five feet in height and two to three inches in girth. Three acres of steep and rocky land have been excluded from the plantation.

The Elladalluwa clearing of thirteen acres, started in December, 1889, is doing well. The plants put in were sapu, grovilloa, lunumidella, jak, tugasaman, milla, and iron bark. The lunumidella, as usual, has taken the lead, being on an average 9 ft. 3 in. in height and 6½ in. in girth, some trees having reached a height of 14½ ft. and a girth of 10 in. On the whole the growth has been somewhat more rapid than that on Judge's Hill. About six acres of patana land near Bandarawela were holed and got ready for planting with *Pinus longifolia*, but owing to some delay in the despatch of the seeds a large percentage turned out to be bad. A few belts of *Eucalyptus robusta* have been put in as a protection.

The strip of forest cleared of worthless timber in the Haputale forest in 1889, and replanted with *Eucalyptus*

robusa and *Acacia melanoxylon*, has come on splendidly, and there is not one vacancy on it. The average height of the saplings is from 10 ft. to 12 ft. and the average girth over 6 in., the *E. robusta* being of the two species by far the most vigorous grower. All the land cleared during the year has been planted with *E. robusta*, with some acacia and some *Pinus excelsa* seed. This seed, however, had been kept too long and did not germinate.

In Sabaragamuwa, besides the block of 15 acres for Para rubber mentioned below, a site for a nursery was selected in the Gabbilankalana, about five miles from Ratnapura, and teak seed from Burma put into carefully-prepared beds. A good deal of the seed turned out to be bad, and the plants in the nursery do not appear to be very healthy. About thirty acres have been cleared of underwood, and teak seed and about 2,000 jak plants have been put in at a distance of 20 ft. by 20 ft. The Assistant Conservator is very eager to start planting a valuable reserve of teak, jak, na, bal, ko., as soon as sufficient funds can be obtained by Government. I have little doubt that a large plantation of this sort, situated in a convenient locality as regards export, will in the long run pay very well.

In the North-Western Province two small plantations were started in the Kurunegala District during the year. The first is called Kumbalipola, and is situated about four miles from Kurunegala and near the Negombo road. About ten acres were planted up with teak, jak, kumbuk, and halmilla. The plants suffered a good deal from drought, but since the rains they appear to have recovered, and the proportion of failure is not 15 per cent. Since this land was cleared, thousands of lunumidella plants have sprung up naturally, some of them running up to 6 ft. in height in the last five months. The second plantation is in the Snuwapola proposed reserve. About eight acres have been planted with jak, teak, satin, na, and mabogany. About 25 per cent. of the jak plants have been destroyed by cattle and about 15 per cent. of the other species have succumbed to drought.

The Assistant Conservator reports that the teak plantation at Puttalam still continues to be a great success. During the year it has however been subjected to a good deal of ill-treatment. The Forester for the time being did some serious damage by thinning out every alternate line of teak poles in the plantation of 1886, against the distinct orders of the Assistant Conservator and of the Conservator. Such a "rule-of-thumb" procedure is not Forestry, and does not do credit to the officer in question.

A number of teak, jak, satin, and mabogany were planted during the year, but the drought was very severe; the water supply ran out and a large percentage of plants died.

The Assistant Conservator, Sabaragamuwa, cleared a block of 15 acres of land at Edugoda on the right bank of the Kalu-ganga for the planting of Para rubber. The holes were made 12 ft. apart and filled with plants which had been first raised in supply baskets. When the floods came every plant below the water-line was destroyed. This was rather disappointing, as it was considered that occasional flooding was good for this plant, and for this reason a low-lying land had been chosen. Hates did considerable damage to the remaining plants when they were about six inches high. Thus there are only 1,872 well-established plants remaining. These, however, are doing well. It was the intention of the Assistant Conservator to fill in vacancies with stumps from Henragoda, but the rains of November and December having failed he was obliged to put them off until this year.

Seed of *Cedrus deodara*, *Pinus excelsa*, and *Pinus longifolia* was supplied through the courtesy of the Conservator of Forests, School Circle, North-Western Provinces and Oudh. The *deodar* seed and most of the pine seed went to the Nuwara Eliya District, while a couple of pounds of pine seed went to the Assistant Conservator, Uva, to try on Uva patanas. The *Pinus longifolia* seed has come up beautifully almost everywhere, whether in the Nuwara Eliya nursery or in the Nannu-oya clearings, but not so well on the patanas near Bandarawela. The *deodar* has not come

up so well, and the *Pinus excelsa* can be considered to be a failure. I believe, however, that a large proportion of the *Pinus excelsa* seed was worm-eaten.

Tank seed was also received from the Conservator of Forests, Pegu Circle, Burma, and from the Conservator of Forests, Travancore. The seed has been distributed in three Provinces. The Burma seed was however reported to be much worm-eaten.

We have made this long extract as of special interest to planters and others who may feel the necessity of planting up portions of their land with trees for timber and fuel. At the higher altitudes the best exotics seem to be *Acacia decurrens* and *A. melanoxylon*, with *Eucalyptus robusta*, *E. rostrata* and *E. globulus*. Still more successful generally is the beautiful *Grevillea robusta*. *Cryptomeria japonica* seems likely to be a success, but the Himalayan cedars and pines seem slow of growth. Excellent for firewood are the casuarinas and frencels, both sending out a multitude of branches. The iluk grass noticed by Mr. Broun (the dreadful along-along of the Malay Peninsula and Java) is not prevalent at high altitudes. There is nothing more annoying than the receipt of seed, either immature, or deprived of its vitality by long keeping; and it will be observed that the forest department is no more exempt from such worries than are private planters. *Pinus excelsa* is the only tree mentioned of which we have had no personal experience. On the other hand *Pinus sinensis* promises to be a great acquisition at high altitudes. Many of the forest trees of China and Japan ought to succeed on our hills. The connection of natives with the Government plantations is scarcely what we should think would be satisfactory. They are supposed to cultivate tree plants for the Government while cropping the ground for themselves. The lion's share of attention is pretty certain to be devoted to the crops of grain and vegetables. Forest roads are much wanted, and there is an "outery" for houses for the officers, especially those who have families. Curiously enough the forest department of Ceylon is specially interested in "the northern arm" for the Colombo breakwater!

The site of the Central depot in Colombo appears to be still unsettled on account of the possibility of construction of a Northern arm of the Breakwater. For this reason the Government Agent of the Western Province desires to shift the site to Beirs, near the Government Factory. The only drawback will be want of space and the distance from the Breakwater, an item of some importance as regards ebony, which hitherto could be shipped direct from its depot at the root of the Breakwater. It is time that substantial buildings be built somewhere, as the timber now lying in depot is exposed to many deteriorating influences. We are told that

Two wiro shoots, each 1,500 feet long, were purchased for the Central Province in connection with the firewood supply to the Railway, and set up, one in the Nanuoya strip telings and the other in the Kotagala reserve above Darawella. As regards the Nanuoya shoot, it was much neglected and the rollers were ruined owing to want of oil and careless loading. The small wiro shoot in the Haputale forest is doing good work.

The total value of timber and other forest produce should during the year amount to R371,215-03, against R337,120-81 during 1889 and R169,310-80 in 1880. Of these R371,215-03, the value of produce sold to Public Departments amounts to R238,988-19, and of that sold to the general public to R132,226-93. Mr. Broun in treating of supplies of sleepers for the railways states:—

I am convinced that before long we shall have a considerable demand for palu and kumbuk sleepers. Kumbuk bridge planks have been proved to last ten years, and the objection to palu, viz., that it is likely to split, has now been removed, for the Assistant Conservator, North-Western Province, reports that

trees which had been girdled in 1889 and felled in 1890 showed no signs of cracking. Both trees are abundant in the forests and grown to a large size. "Large size" inadequately describes the kumbuk trees on the banks of rivers, especially in the North-Central Province. The word "enormous" alone can give an idea of some such trees, with immense oaves in their trunks and calculated by Mr. Henry Parker when dislodged by floods as striking against the "Tekkam" (Giant's Tank ancient) with a weight of five tons. To the Telegraph Department posts have been supplied of pandakasa (*Eugenia bracteata*) and ranai. Who is the enterprising but apparently eccentric engineer of the Uva Province who has been giving trouble to the Forest Department after the peculiar fashion thus detailed?—

In Uva, where transport of heavy timber is exceedingly difficult owing to the hilly configuration of the country and to the distance of the forests from the centres of utilisation, a good deal of unnecessary trouble was caused by the Provincial Engineer indenting for large pieces which he would afterwards saw up into smaller sizes in the saw mill he had erected in Badulla. It is rather hard that the onus of justifying the existence of this turbine should fall to the Forest Department. The Assistant Conservator reports that one order was for 390 pieces 12 ft. by 7 in. by 6 in., which had to be transported 29 miles over rough ground, and which were intended to be sawn up in Badulla into half-inch reapers. On another occasion a representation was made to Government to the effect that no timber could be got from the Badulla depot. As a matter of fact the depot was always well stocked, and delay was due to the omission, on the part of the Provincial Engineer, to inform the Assistant Conservator of the order in which he would require different pieces of timber. That delay in construction of buildings is not always due to the action of the Forest Department, is proved in another instance which came under my own observation in the low-country of Uva. Free permits were given to the Public Works Department to fell timber for the construction of resthouses at different places between Koslanda and Tausuilwila. Large heaps of round timber can be seen lying at different places along the road, and they have been lying there so long that they are being utterly ruined by exposure and white ants. This will be further alluded to under the heading of "Free Grants of Forest Produce."

About 400 tons per annum of ebony are needed to supply the market, and it is to be supplied in the proportions of 300 tons from the North-Central Province and 100 from the Northern. We supposed from this that the forests of the Eastern Province have been denuded of their once rich stores of ebony? It seems that dead halmilla timber, of which there is a large quantity, is usually sold to Indian traders, who bring in rice, and take back cargoes of timber.

A very important function of the Forest Department is to supply fuel to Government establishments, especially the railway. It would be very interesting and useful, if a list were given of trees growing at high and low elevations, native and exotic, best suited to be grown for fuel purposes. Pending the publication of such a list the principle may be accepted, that the harder the wood is and the closer the texture of the timber, the better will be its calorific properties. Trees suitable for timber when grown to a large size make good firewood when coppiced, and planters have a right to look to the Forest Department for the result of the experience of its officers as to the trees which best bear repeated coppicing and yield, in the shape of coppice growth, the highest returns of serviceable fuel. The *raa*, which Mr. Strong told us was one of the best trees of those which

were used as fuel by the railway, is, like many others, too valuable as a cabinet wood, when well grown, to be made into fuel. Its merits are that it coppices so well and throws up so many shoots, which, every three or four years, are available for fuel. There is a species of kekuna (not that with the beautiful silvery leaves) which from the quantity of resin by which the timber is permeated, makes specially good fuel, the resin making it objectionable for timber purposes. Of the exotic plants, blue gum makes very fair fuel and coppices freely, but beyond all compare for fuel purposes are the casuarinas. We have had no experience however, of their coppicing properties. The information furnished regarding fuel in Mr. Brown's report is as follows:—

During the year 87,888½ cubic yards were delivered to the Railway, against 78,285½ cubic yards delivered in 1889, thus showing an increase of 9,100½ cubic yards. This is accounted for by the extension of the Seaside line to Alutgama.

The proportion of Crown wood has during this year been much greater than in 1889, the amount taken from Crown forests being 30,979½ cubic yards as against 19,964½ cubic yards in 1889, while the quantity of private wood has somewhat diminished, being 56,407 cubic yards as against 53,321 cubic yards during the preceding year.

The expenditure on this firewood has amounted to R118,914.33, or R1.37 per cubic yard, and the revenue to R131,070.50, leaving a surplus of R12,156.12. If this surplus is to be considered to represent the royalty on the 30,979½ cubic yards of Crown wood, this royalty would be of 39½ cents per cubic yard, which is certainly not a very heavy profit.

Figures are then given which reduced the royalty to a little over 34½ cents per cubic yard.

The surplus is more than swallowed up by expenditure on firewood plantations in the Central Province and by expenditure on surveys, &c., of forests set apart solely for the purpose of giving an assured and steady supply of firewood to the Railway. Before long the Railway Department will be able to draw all its supplies of firewood from Crown forests, and the private forests will be able to satisfy the demands of the general market in Colombo.

A sum of R500 was placed at the disposal of the Superintendent, Railway Fuel Supply, to make an experimental coppice in the forests near the 43½ milepost. About fifteen acres of forest were cleared and the stools cut flush with the ground. The stool shoots are reported to be springing up freely except in one spot, where the lantana is giving some trouble. The cost of coppicing and of transport amounted to R499.72. The yield has been somewhat meagre, only 701 cubic yards, the forest being of a poor quality. The portion taken over by the Railway Department by the end of the year, viz. 174 cubic yards, almost entirely second and third class firewood, yielded a revenue of R620.49, or R1.309.10 per cubic yard. At the same rate of classification the 701 cubic yards will give a revenue of R917.60, *i. e.*, a net revenue of R417.88, or of R27.86 per acre.

Should the system of coppice prove to be successful in these forests, it will no doubt be the best to adopt so as to obtain at small cost a continuous supply of firewood for the Railway.

Fuel Supply to other Departments.—In Colombo, 3,071 cubic yards of firewood were sold to the Prison Department, the Harbour Works, Government Factory, Government Printer, and Master Attendant. In Uva, 1,032 cubic yards of firewood and 31 bushels of charcoal were sold for R3,106.

Fuel Supply to the Public.—In Jaffna, 2,285 tons of dry firewood were sold to the public for R11,482. I heard that the Government Agent, Northern Province, towards the end of the year took exception to this method of disposing of firewood from the Crown forests, and that since then he has closed the firewood depot. I inspected the firewood depot and the forests from which the firewood has been brought to market, and have been unable to see why the arrangement in Jaffna

should be disturbed. The removal of top pieces and dry timber lying about the forests, under proper supervision, is very beneficial to the forests, while, if purchasers are let in under permits, there is every chance of their helping themselves to whatever comes handy. In Uva, 439 cubic yards of firewood and 1,410 bushels of charcoal were sold for R1,449. Mr. Moss is still the only officer of the Department who has attempted to make charcoal according to more advanced methods and the outcome is still somewhat light and overburnt. The system of purchasers being allowed to remove timber or firewood from the forest, is manifestly objectionable. The returns from minor forest produce, especially gallnuts in Uva is increasing. Fees are charged for animals allowed to graze, and in Ceylon as in India, great care is requisite to secure abundant grazing grounds for the owners of cattle, while duly protecting the property of the public in forests. Here as in India the native cultivators, when permitted, collect green leaves from the forest as manure. Of course the forest soil is impoverished in proportion to the quantity of vegetable matter removed; and in India the system of *rah* culture has led to much discussion and controversy. Under the heading "Free Grants of Forest Produce," Mr. Brown writes:—

The free grant of timber and other produce for works of public utility is, where funds for carrying them out are scarce, highly commendable, but there is no reason why expensive timber should be given away when others less in demand would do just as well. An instance of this sort is given by the Assistant Conservator, Central Province, who states that 16 satinwood and 8 milla trees were granted, without his knowledge, for the construction of an ambulance at Elahera. Nor is it advisable to grant permits for indiscriminate cutting when the timber is afterwards allowed to rot on the ground. I have before mentioned the case of free permits being given to the Public Works Department for the construction of rest-house buildings. It seems very strange that the Public Works Department should not have been able to afford to pay for this timber, when the Provincial Engineer managed to bring all the way from distant places like Tanamilwila, Telula, &c., Cazanore tiles, which cost about R75 landed in Colombo or about R100 brought to final destination, when shingles capable of lasting for twenty years or so could have been obtained at a much cheaper rate on the spot. The Assistant Conservator, North-Central Province, reports that Ungala Ratemahatmaya has over R5,000 worth of timber stored on his premises. His authority is apparently a verbal permission received from His Excellency Sir A. Gordon to fell as much satinwood and halmilla as he requires. It appears to be time to moderate the ardour of the Ratemahatmaya.

We should think so. The friction between officers of the P. W. D. and Forest Departments, now so severe, will, we suppose, abate with the mellowing influences of time. It seems clear that if the Forest Department is to be held responsible for the good condition of the Government Forests and the conservation of their products all supplies of timber, fuel, &c., should be furnished through its officers and depôts. It is satisfactory to learn that in 1890

For the first time since the organisation of the Department, the revenue credited in the Treasury has exceeded the expenditure. The net surplus to the Department amounts to R88,527.83, while during 1889 the deficit amounted to R63,205.42 and in 1888 to R16,977.20.

Out of R510,044 total receipts, fuel for the railway yielded R131,070, an amount which is likely to increase materially, year by year, as the railway system extends, unless malaria science helps the world in respect to a cheap and good artificial fuel. After giving figures, Mr. Brown states that

they show.

That there has been a considerable rise in revenue under all Budget heads, the rise under I. being due to the payment of large outstandings due by the Hapitale Railway Extension, to outstandings due for sleepers to the Western Province, to the sale of 266 tons ebony in the Central depot to increased Railway fuel supply, and to a large increase in the sale from depôts in all Provinces, this increase being most marked in the North-Western Province and in Uva. Against R510,044 revenue, the expenditure of the department in 1890 was

R921,517-12, of which R309,502-65 was for Conservancy and Works and R112,014-47 for Establishment.

To obtain the large revenue for timber a large outlay was also required, and this as well as outstandings due by the Department, chiefly on account of timber supplied to the Hapitale Railway Extension, account for the increased expenditure under heading 1, "Produce sold from depôts." The extension of areas under plantations in the Central Province, North-Western Province, and Province of Uva necessitated an increase under the head "Demarcations and Improvement," while Forest Settlements, chiefly in Sabaragamuwa, also caused an increase of expenditure under the same head.

In dealing with the details of establishment, Mr. Bronn states

As regards salaries, I again beg to draw attention to my remarks under the heading "Protection and Improvement." What the Department wants is a good staff of efficient Rangers, assisted by Forest Watchers, who would be under their immediate supervision, instead of headmen who are in no way responsible to them, and who can plead various excuses for not attending to forest work. The object to be aimed at is not to fill up the next vacancies in the superior staff, but to devote the sums to the increase of the subordinate staff and to the improvement of the prospects of a crop of officers who live an arduous life without at present any prospect of getting a rise in their meagre salaries. On the money at present expended an establishment decent, if not brilliant, prospects would be assured, not only to the superior staff, but to the whole of the subordinate establishment. It is not between the P. W. D. alone and the forest department that regrettable friction exists. The subordination of the forest officers to the Government Agents and their Assistants, naturally enough leads to trouble where one or both of the officers brought into contact are not prepared to sacrifice personal feeling and official dignity to the good of the service and the interest of Government. It is to be hoped that the relations of the respective officers in the Northern Province are more amicable than they seem to have been in 1890, judging from the following statement:—

This year the Department has been worked on the lines adopted at a durbar of Government Agents held in Colombo in October, 1889. The system of working through Government Agents and Assistant Government Agents has worked that a good deal of friction has been caused in others. There is no doubt fairly well in some Provinces, but there is no doubt that the system, to work well, must depend on the good will of the Government Agent towards the Department, and that if he does not support the Assistant Conservator, or does not allow him to give orders to his subordinates direct, the work will become disorganised and will eventually come to a standstill. This has been the case notably in the Northern Province, where the want of co-operation between the Government Agent and the Assistant Conservator has brought the working of the Department practically to a standstill. A Departmental Code, which will set forth the relations between the Department and the Revenue Officers, is much needed.

We quote the concluding paragraphs of this interesting and suggestive report:—

PORTABLE STEAM SAW MILL.—This saw mill, which had been ordered from Messrs. Ramsome & Sims through the Crown Agents, did not reach us during

the year. The money therefore which had been kept to defray its cost lapsed at the end of the year, and a sum which it was intended to devote this year to the formation of an elephant establishment will have to cover the expenditure on the steam saw.

ELEPHANT ESTABLISHMENT.—One young elephant was purchased in the Eastern Province. It was intended to buy three more during 1891, but for the reasons stated above this has had to be put off.

DESTRUCTION OF GAME.—No stop has as yet been put to the indiscriminate destruction of game. The Assistant Conservator, Uva, records a case where several deer were slain solely for their hides, and the carcasses left to rot by the roadside. The chief offenders are Moormen traders, who go into Provinces where they can have possibly no right of hunting, and kill game and cause it to be killed in large quantities by villagers. They are not affected by close seasons, and it is sometimes very difficult to obtain convictions, for certain Magistrates will not take skins, however fresh, as evidence against the offenders. Strict rules are required to protect elephants against so-called "sportsmen," who go into a herd and do not satisfy themselves with the hulla, but shoot cows and calves. None but rogues should be shot at, and there should be kept in each Kachcheri a list giving particulars of the beat of any rogue elephant in the district, and it should be made penal to fire at any other elephant except in self-defence, on a public road, or when it destroys crops or other property.

HERBARIUM OF FOREST TREES AND COLLECTION OF CEYLON TIMBERS.—This has been largely added to during the year both by Colonel Clarke and myself, and I have to thank Messrs. Alexander and Armitage for considerable contributions. The collection of Ceylon timbers has also been much increased, the Assistant Conservators of the Central Province and of the North-Western Province, and the Superintendent of the Railway Fuel Supply being the chief contributors. Duplicate specimens have been sent to the Director of Public Works and to certain firms in Colombo.

GIRDLING OF PALM TREES PREVIOUS TO FELLING.—Only one report on the subject has been received. Mr. Fyers reports that towards the end of the year he had girdled twenty palm trees out of forty which he had girdled in 1889 and that the results are most satisfactory, the logs having hardly cracked at all. As cracking has hitherto been the great obstacle against a more universal use of this valuable timber, it is to be hoped that in future all palm trees will be girdled at least one year before felling. This will probably do with away the objection which the Railway Department has of using palm sleepers.

COLLECTION OF FRUIT AND HONEY BY VILLAGERS, &c.—Some action is urgently required to moderate the damage done by villagers and others in the collection of certain kinds of fruits and honey. The most striking instance which I have come across was the collection of psalu fruit in the Northern Province. The trees of this most valuable species, are so hacked to pieces or torn and broken that the broken and cut branches form, in many places, real hedges along the sides of the roads. The result is that an enormous proportion of the psalu trees in the Northern Province have been unsound from their infancy. There is no reason why, if the collection of the fruit must be allowed, this persistent vandalism be for ever winked at. There is no difficulty in collecting the fruit without injuring the trees, and there is no necessity why people not usually residing in the island should be allowed to do all this damage. I have noticed similar damage in Bereliya forest of the Matara District, where the villagers collect the fruit of the bereliya dun. As regards the collection of honey, it is no rare thing to see a tree felled merely for the honeycomb which it bears. I know that, at present, until a proper establishment is set up, it is difficult to check all this damage, but the Government Agents can do a great deal towards stopping it by using their influence and warning villagers that reckless waste will be severely dealt with. Mr. Bronn will see that Government in the Ordinance just passed has provided remedies against the wanton shooting of elephants and the reckless

slaughter of game, and we trust that without stopping the collection of the fruits of the *palai* and *bereliyandain* trees and of honey it may be possible to prevent the damaging or destruction of valuable timber trees.

We feel sure the larger proportion of our readers will share the interest we have felt in this report,—which so largely supplements the information contained in reports of the Botanic Gardens,—and will feel that we only performed our duty, especially to the agricultural enterprise of the colony, in commenting so fully, and quoting so freely as we have done. Hitherto the operations of the Forest Department of Ceylon has been mainly tentative and preparatory, while the obstacles to be overcome have been and are many and serious. But now in each successive year we may look for increasingly better results, not only in immediate money returns, but in the foundations laid for future wealth, in existing forests improved in respect to natural reproduction and plantations formed not only of such valuable exotics as mahogany, teak, padonk, the gums and acacias of Australia, and the cedars and pines of the Himalayas, but of the choicest of our numerous indigenous trees, such as ebony, satinwood, halmilla, dan, &c. Amongst the indirect benefits of the operations of the department we must class the largely sanitary effects of running roads and paths through the forest and letting light and air into pestiferous jungles where previously

No beam of the sun or the sweet moon has entered with cheerful and purifying effect.

Already at the end of 1890, there were forest cart roads opened equal in mileage to 1'75 in the Central Province and 92'5 in the Northern. Bridle paths 3 miles in the Central Province and 7'05 in Uva. Inspection and export paths 8'9 in the Western Province, 3 in the Central and 4 in Uva: a grand total of roads and paths equal to 115'45 miles. And this process must go on at an accelerated rate as the forests are exploited and their produce conveyed to the various depots. Ceylon is already one of the best roaded countries in the world, and what with railways and principal roads formed by borrowed money, votes from revenue and appropriations of money and labour under the provisions of the Thoroughfares Ordinance,—with grant-in-aid roads and new roads and paths opened by the Forest Department, the railway and road map of Ceylon for 1900 ought to be a scene of ramified scorings, such only as the maps of very advanced countries can equal or surpass. Buildings constructed by the Forest Department will meanwhile follow the roads in opening up and imparting life and health to the jungle solitudes, which, by and by will be solitudes no longer.

A VISIT TO WALDHOF NEAR MANNHEIM:

THE GREAT QUININE AND CHEMICAL WORKS OF MESSRS. C. F. BÖHRINGER & SOHNE.

I remember when on a visit to John Eliot Howard of Cinchona fame, during which the good old host treated me with the utmost hospitality and kindness, hinting at a wish to see over his far-famed Quinine-preparing Works, and very quickly realizing that the rule of "no visitors allowed" was not likely to be broken through in this case. All the greater therefore was my appreciation of the cordiality with which in response to the letter of introduction from Mr. Böhringer of Colombo, forwarded from Munich, his cousin, the head of the Waldhof house, intimated his readiness to meet and show us his extensive works. Of course, when Quinine was from 16s to

£1 an ounce, these were no doubt weightier reasons for guarding the process of manufacture or extraction as followed by the best houses from the observation of outsiders; while now that the valuable febrifuge has tumbled down to a fraction of its former value, and that only large capitalists with expensive machinery and a skilled staff capable of manufacturing large quantities very cheaply can hope to make any profit, it matters very little who is taken through the works. Still, there are very delicate processes at work, and the rule is followed of privacy in most chemical manufactories, the staff being specially bound in their terms of service. All the more courteous, therefore, was the readiness with which we were permitted and conveyed through the very extensive and interesting establishment to which we are now about to refer.

We learned incidentally that the grandfather of the present head of the house lived in Stuttgart, and there interested himself as a practical chemist, but it was his son who first established a Quinine and Chemical Manufactory and who at length located himself at Mannheim until a large fire destroyed his establishment there, and the firm of Messrs. C. F. Böhringer & Soehne opened in Waldhof on a site facing the Rhine and admirably adapted for the purpose in view. Mr. Böhringer, senior, died last year, leaving his son, now in the prime of life (about 35 years), at the head of the very extensive and responsible business associated with his firm.

On our visit, we travelled in the early afternoon of a pleasant sunshiny day—the last in September—from Heidelberg to Mannheim. There we were met, and leaving our impedimenta at this station, took another train to Waldhof—a wayside station chiefly for the service of two or three large factories (of glass as well as chemicals) and the village connected therewith. The country was everywhere flat though backed by the hill-ranges in and beyond Heidelberg seen in the distance. In walking from the station to the great Chemical Factory, we drew near to the Rhine, here by no means so important a river as it is lower down. We notice that the soil is extremely poor and shallow, and even where under cultivation, there are numerous patches intermingled, apparently useless for crop-bearing and left untouched. On such soil, a site for Chemical Works may well be found. The Waldhof establishment has formed a village of its own; for notwithstanding improved processes by which one worker can now do the work of twenty, the firm has altogether, some 300 employees in this its leading establishment, apart from its branches at Milan and Amsterdam, a mercantile house recently established in New York and the Ceylon Agency. The first noticeable feature as we approach the works is a huge mass, almost hill, of dark brown refuse which is being constantly added to from trucks carried by a wire tramway across the roadway from the works to the top of the long mound. "That we call Ceylon"—said Mr. Böhringer—"for indeed it may all belong to your island, representing in fact the greater part of the cinchona bark imported from Ceylon,—the bulky residuum after the extraction of the quinine alkaloids. No other evidence was needed as to the extensive operations of the firm than was presented in this great mass—equal in length and height to one of the larger embankments on the Ceylon railway—and all the result of about seven years' work. I learned afterwards from the leading Doctor-Chemist of the Works that everything possible had been done to utilize this stuff, but in vain: it does injury rather than

good when applied to the soil in its present condition; but Dr. Schäfer anticipates that when very much older it can be profitably utilized, pointing in evidence to a layer in another direction which as it decomposed after a good many years, got a covering of vegetation over it.* Of course, it may be said what an argument have we here for a system of extracting the alkaloids roughly in Ceylon, India or Java—such as the Java planters are said to be now proposing—and so saving all the packing, transport and freight of so much useless material. But in the days of cheap quinine, even more than in the past times of a dear article—strange to say—is this unlikely to be profitable; for no one who has seen, as I now have, the multiplied and elaborate processes by which the alkaloids are secured on a large scale, can expect any works that may be established colonially to compete with the European manufacturers. The great object in these days is to prepare a very large quantity of quinine in the most economical way possible, and in this work the Waldhof establishment, thanks to the skill of chemists and its elaboration of new improved processes, has secured pre-eminent success. Freight, too, have fallen greatly of recent years, and altogether there is reason to believe that the Java planters will only burn their fingers by sinking capital in local works, even to secure the alkaloids in the rough, and that they cannot do better than continue to ship to Amsterdam which now, and henceforward, is likely to supersede London altogether as the great cinchona bark depot and mart.

It may be supposed that I am merely here re-echoing the sentiments of European manufacturers; but I heard very little on the subject at Waldhof, and am rather giving the impression left on me from the inspection of the manufacturing processes on a large scale. But I have thus plunged into the middle of my subject before entering the works: at the same time, even if I were capable, it cannot be expected that I should give a detailed account of all I saw. Mr. Böhringer in his sanctorum—in the Library of which the "Ceylon Handbooks" and *Tropical Agriculturist* occupied a prominent place—introduced me to Mr. Mehl who, for many years, has represented the firm as the buyer of bark in the London market; but whose vocation as "English buyer" has almost disappeared, so much have the sales dropped in importance, through the falling-off in Ceylon exports, while those of Amsterdam have risen correspondingly with the greatly increased import of Java bark. For instance, the London sales following my visit were pointed out as to be absolutely insignificant for the quantity of bark offered; while Java had just made an unprecedentedly large export (for week or fortnight). The Waldhof firm is, of course, kept telegraphically informed by its Agents of the shipments of bark from all ports of any importance, and the Assistant in charge was at once able to give me the latest figures for Ceylon, Java, &c. They have also the best available information as to planting, crop prospects, estimates, &c. I could, of course, give only a poor account of Ceylon, in view of the low prices prevailing for bark, and remarked how astonished John Eliot Howard would be, if he "revisited the glimpses of the moon," at the marvellous fall in price of quinine which had taken place and at the failure of his prophecy that Ceylon would always find a profitable market

for a good bark yielding two per cent and upwards. I did not hear much at Waldhof to encourage the expectation of a speedy revival of better quotations; but it was stated that consumption had certainly been stimulated by the cheaper rate for quinine, and that in south-eastern Europe and America—the firm has lately opened a special branch house in Cedar Street, New York—the demand was very satisfactory. Still, it is supposed, there is a good deal of quinine, though not bark, held back in London, from some years ago; and it is impossible, Mr. Mehl says, to get exact information on this point. If it were known as a fact that all such back stocks had been cleared off, the market would probably become more buoyant and encouraging, though the large shipments of "Java" more than counterbalance the diminished exports from Ceylon and India. Meantime, at Waldhof, the profit is looked for through the improved means of turning out large quantities of quinine in its various combinations, cheaply, rather than through any marked improvement in the present low rates. But it would be a great mistake to suppose that the Waldhof works, any more than those of the Howard's or Whiffin, are dependent solely on quinine. Nothing more astonished me than the great number and variety of chemical preparations—some of them requiring separate buildings altogether and distinct staffs and their trade, or volume of business, being perhaps of more importance than that in quinine. For instance, such preparations as glycerine and salicylic acid are in very extensive demand (partly for fruit preserving), especially in America; and in their latest "Market Report and Price Current," Messrs. Böhringer report of the former that "there have been large quantities contracted for, so that for the moment we are fully engaged."

Here again however, I am forestalling. After our talk on the producing countries, exports and markets, we were introduced to, and handed over to the care of, Dr. Schäfer, the head of the scientific staff, who, in the full vigour of his robust frame, one could see at a glance was a man of keen perception and power. He spoke English well—as did all the other gentlemen we met—and had seen the cinchona-producing world in South America, where heeidea superintending or inspecting plantations for a time, he had penetrated to some of the primeval groves of the tree in its native habitat. Dr. Schäfer occupies a most responsible post at the head of the staff in the various departments included in the Waldhof works, and the great variety and extent of the operations may be judged from the fact that there are under him about a dozen qualified chemists (all holding a Doctor's medical degree I believe) and most of whom keep so strictly and continuously to their own laboratories and the chemical works to which they are attached, that they never enter any other's. In fact, as Dr. Schäfer mentioned, anyone knows nothing of what the others are doing, and we were honored by being taken over a whole establishment which is a mystery and a thing unseen and unknown by eleven out of the twelve doctors and perhaps 200 out of 300 employees in the place! The workmen employed are also strictly bound by engagements and conditions and I suspect are too well off to care for change, much less to give offence. In some departments, a good many young women are employed, and those we saw all looked bright and contented. The works consisting of a long stretch of strong and high masonry buildings with detached structures for special preparations and the inevitable lofty chimney stalks for the steam engines, are by no means shut in or walled round. Not far off, a glass manufacturing

* Mr. Mehl afterwards told me that Mr. Whiffin of London has found a good market for some of his chemical refuse—for instance that of "Nux Vomica" from which strychnine had been extracted, as a covering for garden walks, to prevent the growth of weeds or other vegetation.

establishment (worked I think it was said by a little French colony) was pointed out to me, which not only is strictly enclosed, but is almost self-contained, so that no one unconnected is permitted to enter, and the occupants hold only the most scanty communication with the local outside world. The Waldhof Chemical Works are, however, secluded enough in situation with quiet a frontage on the Rhine—which is not much frequented here by passenger boats—and with such poor land (for soil) in the neighbourhood, that the cultivators are few and far between. No better or more convenient site—between railway and river—for extensive chemical works could well be chosen. The site was chosen and the works commenced here some 40 years ago I believe; but within the last ten years they have been greatly changed, improved and extended. As Dr. Schäfer mentioned, in respect of quinine alone there were some years ago, more people required to turn out one-eighth of the quantity now manufactured! We first visited the rolling and grinding mills where the cinchona bark is reduced to powder; then came a series of chemical processes in enormous vats, at various altitudes, up and down iron stairs, and with the aid more or less of petroleum &c., and of machinery (some of it hydraulic) in extracting and clearing the alkaloids. At one stage Dr. Schäfer pointed out how by an invention of his own (I think) one man with the aid of machinery, was able to do what it required twenty men to carry out before. The clarifying processes (with charcoal largely) and the whitening of the quinine were especially interesting. There were some centrifugal machines—a recent improvement I gathered—attended to by women—on which cables of the quinine were spun at the rate of 1,000 revolutions a minute, in connection with the drying and crystallization of the finished product which were simply delightful in the completeness of their adaptation to the end in view. It would be a great mistake to suppose that ordinary "sulphate of quinine" is the only or main product in this department; at Waldhof there are prepared no less than 38 varieties of "quininae" from "quininae hypopospis" at 2s 8d the ounce (I quote from the September Price Current) down to "quininae tenues in lumps at 6d"—the bisulphate and sulphate being given at 10s, the "citras" at 1s 2d, "hydrochloras" at 1s 2d, hydrochloras amorphous 4½d, "pure quininae" 1s 11d, "quininae areolias" 1s 3d, "arsenias 1s 9d," and "quininae valerianae free from cinchonidia at 1s 5d"—that is for quantities—the rule being tins of 25, 50 or 100 ounces free for package; bottles "of 1 oz., 2d per ounce extra, bottles of 4 oz. 1d per ounce extra, cases of 250 ounces or more free." I have merely selected a few of the 38 combinations of "Quininae," besides several of "Cinchonidinae" and "Cinchoninae"—prepared to suit every variety of taste or prescription and for each and all of which, no doubt there is a demand in different countries if not in all. The Assay Rooms, where two or three of the Doctor-Chemists are, from year's end to year's end, busy analysing cinchona bark (and other raw material) of course with far more delicacy and accuracy than are known to us in the East, were not the least interesting; and in Dr. Schäfer's own office, the collection of chemicals, all the product of the works was quite bewildering. One he showed us worth far more than its weight in gold; while a milligramme of another would be enough to kill a strong man.

After the Cinchona Bark or Quinine Department, that for extracting Cocaine, which has now come so much into use, was gone over. It will be of interest to quote exactly the list in the Price Current

under this head:—

COCAINA		gramme.	5 per cent.	Free
Pure in bulk	ozs 24s 6d	1s 0d		tubes of 1 gramme
COCAINAE				
Benzos	0s 11½d	do	do
Bimurias	0s 10½d	do	do
Boras	0s 10½d	do	dn
Hydrobromas	0s 11d	do	do
oz.				
Hydrochloras P. B. cryst.	21s 6d		do	tins of 25 oz.
do	do	22s	do	bottles of 1 oz.
do	do	22s 9d	do	tubes of 1 gramme
gramme.				
do	do	0s 10½d	do	do
do	do	1s 1½d	do	tubes of 1 grain
do	powdered at same prices		do	

SPECIAL QUOTATION FOR CONTRACTS:

Our Cocaine Hydrochlorate is in beautiful, well defined crystals and entirely free from amorphous matter. It is also free from Benzoylcegonin. It stands MacLagan's and every other test.

COCAINAE		gramme.	5 per cent.	Free
Nitras	0s 11d		tubes of 1 gramme
Oleias 50 per cent	0s 10d	do	do
Salicylas	0s 10d	do	do
Sulphas	0s 9½d	do	do
Tartas	0s 9½d	do	do
Tannas	0s 6½d	do	do

The market report states that "Cocaine is in very good demand, the supply of leaves is very small and owing to the rainy season there can be very little brought over during the next few months and we have therefore to look for higher prices." This should encourage some Ceylon planters to pay attention to their plants of *Erythroxylon Coca*, though as yet the leaves received from Java and Ceylon have been poor (immature probably) as compared with the South American supply. Another preparation in large request for America and the Colonies it seems—for killing prairie dogs, bears and perhaps noxious vermin—is strychnine which in "pure crystals" is sold at 2s 1d per ounce, but is supplied in some ton forms altogether. Large supplies of "Nux Vomica" are required for this and some is got from Ceylon I believe.

The preparation of Glycerine again showed us very interesting processes, and also of "Salicylic Acid," so largely used in Chicago in meat preserving; and finally we saw the recently constructed buildings for the preparation of Ether (from carbolic acid) in which a large business is done. Some of the glycerine is made "free from lime" specially "for soapmakers." Another preparation in which we were interested is "caffeine," the essential chemical property of tea and coffee, and the list of varieties under this head may also be quoted:—

CAFFEINA		lb.	Not	Free
Pure 28 lb. 5s 8d in 1 pkt.	6s 0d		tine of 7 lb.
CAFFEINAE				
Arsenias	2s 2d	do	tins of 25 oz
Benzos	1s 2d	do	do
Carbolas	2s 5d	do	do
Cinnamylas	1s 3d	do	do
lb.				
Citras: P. B. nov.	5s 6d	do	tins of 7 lb.
Citras 28 lb. 5s 8d in 1 pkt.	6s 6d	do	do

Tannas	0s 10d	do	do
Valerianas	0s 9d	do	do

Altogether there cannot be less than 360 to 380 different chemical preparations or varieties quoted in the Price Current of Messrs. C. F. Böhlinger & Soehne of Waldhof, and the elaborate arrangements made at the works—from the

powerful steam engines down to the delicate operations of the chemist and analyst—to secure perfection and economy in operation, must be seen to be duly appropriated. For instance the number of cast-iron pipes traversing the buildings for the service of the various departments arrests attention and one has to learn that not only do these convey hot and cold water, but hot air, cold air, and perhaps different gases.

We parted from our courteous host, and his clever Doctor-Superintendent with regret, greatly impressed by what this afternoon's visits had revealed to us. Mr. Mehl was our pleasant instructive companion back to Mannheim where, after dining together, we took the night train to Mayence. Alluding to the poor soil in the neighbourhood, and how little was done over with the vine, though some quantities of plums and cherries were sent to the English market, he mentioned as the most important industry for the rural people, the growing of vegetables which were prepared and "pressed" for ship use.—Mannheim, a town of 80,000 people is within the limits of Baden and the Grand Duke had left after a short visit to his palace here the day before. It is a handsome, well-built town with broad avenues and side walks shaded by trees and the October festival was about to commence here as in Munich, attracting much attention and a large gathering.

DOVER, Oct. 16th.

The week has been one of very wet, stormy weather here; and one night we had a great burst from a strong gale in the Channel which did much damage at the end and on the Admiralty pier, estimated at £1,000 loss in all. That very evening the Prime Minister, Lord Salisbury, crossed from France himself; but fortunately by the 5 p.m. rather than a later boat. Still, though the storm had not then burst, the crossing was very uncomfortable even in one of the powerful steamers which now, in ordinary weather, do the 26 miles in very little over an hour. On this occasion the hour and a half was exceeded, and we had an amusing account from a fellow-passenger of the Premier's persistent nibbling of hard dry biscuit—all through the passage as he remained in one sheltered spot on dock.

Although the weather of the past twelve months—winter, spring and summer especially—has been so much condemned, I learn that fruit growers of Kent—"the garden of England"—have had no reason to complain, but rather speak of two favourable seasons. Always, the county of gardens and orchards, with the decline of farming and the preaching (by Mr. Gladstone especially) of the duty of extending fruit cultivation in England, great additions to the orchards and gardens have been made in the past ten years even in Kent. I remember in 1884, being struck with the number of fields planted with young fruit trees. Now I hear of men having, individually, as much as 1,000, and over 3,000 acres under fruit for the markets not only of England, but of big towns as far north as Manchester. They begin in the early year cropping strawberries, picking from 3 to 4 a.m. each day, so as to get their crop into London by special train in the early morning; then follow gooseberries, currants (all varieties), raspberries, plums, peaches, apricots and of course apples and pears. The large cultivators making contracts in a big way do well—one acre of strawberries often gives £200 gross return in a year!—but I hear that the smaller garden owners, especially those farthest away from town, often do poorly. One unfortunate in this neighbourhood sent 50 bushels of plums this season

to London, only to get as his return a *debit note for 4d to pay!* The plums had not realized carriage and charges. But talk of the Ceylon Railway, I have heard enough of the misdeeds and overcharges and partiality of the "the London, Chatham and Dover" while here and I must give you some instances in my next.

I have just heard that a Colonel Stewart of Dover Garrison—spoken of as a much liked Highland officer—expects to go to Ceylon by the end of the year as Senior Commissariat officer.

I have just been honored by an invitation from the Council of the Royal Colonial Institute to their Annual Dinner at the Hotel Metropole on 10th Nov. after which in the evening Mr. W. E. Maxwell, C.M.G., is to read a paper on "The Malay Peninsula, its resources and prospects," Lord Brassey in the chair.

PLANTING NOTES.

Formosa Oelongs are cultivated by small native farmers, who have small gardens, and some of whom do not pick over 100 pounds at one picking, of which they have three or four during the season. Unlike Japan, the first picking is the poorest of the season, the second crop is better, but the autumn crop is the best of all. The reason for this is, that during August the island is visited with heavy rains, after which the warm weather of September causes the plant to grow luxuriantly. The leaf is full of sap, added to which is the fact that the moisture in the atmosphere causes the plant to ferment quickly, which allows the manufacturer to cure the leaf without exposing it to the sun, which, it is claimed, takes from its strength. The great strength of the leaf enables the manufacturer to fire the Tea longer, and the longer it is fired the better it will keep. It is a fact that the third crop or autumn Teas, that have been well fired, will improve after having been exposed to the air for a few days in the dealers bin. The action of the atmosphere brings out the fragrance of the Tea, while at the same time the baked flavour disappears. These Teas will keep for a month without much, if any, deterioration; the first crop as will lose flavour as rapidly as Japan.

It is related that in yesteryear, when the Chinese were begged for seeds of the precious plant to send to European conservatories, they secretly destroyed all germination in the seeds by boiling and then presenting them, with their blindest smile, would say: "Belly solly Tea no glow all the samee China."

During the reign of Queen Anne black tea sold from 12s to 16s per pound. In 1707, from 15s to 30s per pound.

"Strange and far-fetched things they only like; don't you see how they swallow gallons of the juice of tea, while their own dock leaves are trod under foot." These words were penned over 150 years ago by Sir Richard Steele, in his "Comedy of the Innoral," but how applicable they are to much of the so-called tea sold at the present day!

The bark "Formosa" brought the first cargo of Formosa Oolong to the United States, where she arrived March 7th, 1869. It consisted of 7,800 half chests, shipped by Mr. John Dood, an Englishman, the pioneer in the Formosa tea business. It is now the favourite tea with most connoisseurs.

"It is a singular fact," writes an American paper, "that the Indians living on a Tea garden will not touch Tea. From hygienic grounds they have been urged to use it, but they spit it out with disgust." Is that so!

St. Louis.

—Madras Times.

THE COFFEE CROP IN COORO, is this season, we are glad to hear, likely to be a good one. There has been an abundance of rain—rather more than enough. Experiments are now being made by some of the planters of growing Liberian plants among heir Arabian coffee, with the hope of improving the species. —Madras Mail, Oct. 29th.

CULTIVATION DURING 1890-1891 IN THE MADRAS PRESIDENCY.

The total extent of cultivation, both of ryotwari and zam lands, in the Madras Presidency during the year 1890-91 aggregated 26,070,494 acres, against 26,118,917 acres in 1889-90, thus falling below the extent of the previous year only by 48,423 acres, or 0.19 per cent. The acreage under first crop shows a decrease but that under second crop an increase, as follows:—

	1889-90.	1890-91.	Differe- rence.	Per- cent- age.
1st Crop.				
Ryotwar ..	18,936,316	18,840,313	min. 96,005	min. 0.51
Inam ..	4,860,585	4,836,943	„ 23,642	„ 0.49
2nd Crop.				
Ryotwar ..	2,033,918	209,448	plus 55,530	plus 2.73
Inam ..	288,093	303,790	„ 15,692	„ 5.45
Total.	26,118,917	26,070,494	min. 48,423	min. 0.19

The decrease under first crop was due mainly to the unfavourable character of the season in almost half of the Presidency, and the increase under second crop to the favourable North-East monsoon in Kistna, South Arcot, Salem and Trichinopoly. The decrease under first crop occurred chiefly in—Anantapur of 84,200 acres, Ondapah 62,700 acres, North Arcot 23,900 acres, Chingleput 12,400 acres, Madras 28 acres, Tinnevely 39,300 acres, Coimbatore 18,000 acres, and Ganjam 24,300 acres. But, to counterbalance this large decrease, the districts of Vizagapatam, Kistna, Nellore, Bellary, Karnool, South Arcot, Tanjore, Trichinopoly, Nilgiris, and Malabar, showed an increase ranging from 0.15 per cent in Nellore to 8.77 per cent in Vizagapatam. This large increase in Vizagapatam is mainly attributable to the introduction of the survey area, and also to the very favourable character of the season. In Nellore it was due to the fact that the ryots cultivated a greater extent of land than on the previous year in expectation of a favourable monsoon, but in this they were sadly disappointed. Malabar shows an increase chiefly in Wynaad, where, since the settlement, when a charge on occupation was substituted for one on supposed cultivation, efforts are being made by the ryots to extend cultivation as far as possible. Considering the character of the year under question and the failure of rains in so many parts of the Presidency, these returns must be looked on as very satisfactory.—*Madras Times*, Oct. 22.

A NEW JAPANESE TEA ASSOCIATION.

The fate of the last association of tea-merchants the *Seichu-gaisha*, has not proved deterrent. Another society, the *Nippon Seicha Gikai*, has now been formed, in Osaka, Kobe, Kyoto, Shiga, Toyama and other western districts. A meeting of projectors was held on the 4th inst. in Kobe, and the following articles of association are said to have been voted:—

Art. 1.—The association shall be named the *Nippon Seicha Gikai*, and its head office shall be at No. 14, Sakayemachi, Sauehome, Kobe.

Art. 2.—The objects of the association are to open a black-tea trade with Russia, and enquire into the actual condition of the tea markets in the United States and Australia.

Art. 3.—To attain the above objects, the association shall send committees to different places to make trial sales of both black and green tea, and to conduct investigations.

Art. 4.—The limit of time allowed for such sales shall be five years from the 25th year of *Meiji* (1892). According to the results attained at the expiration of that time it shall be determined whether to establish a new company, and undertake the direct export of tea.

Art. 5.—Subscriptions shall be raised to pay the expenses of the trial journeys, the subscriptions to be paid by those interested, no fixed amount being determined.

Art. 6.—The subscriptions shall be deposited in some trustworthy bank. The names of the subscribers and the amount of their subscription, shall from time to time be published in the newspapers, as well as

entered and preserved in the office records.

Art. 7.—Any one desiring to make trial sales of the Association's tea shall be permitted to do so without any commission being charged.

Art. 8.—The Association shall hold a general meeting in February every year to report the results and accounts of the previous year.

Art. 9.—Notice of subscription must be sent to the office of the Association before March, 1892; and the cash must be paid in April. According to convenience, subscribers may pay their subscriptions every April during five years, or may pay the whole amount down at once.

Art. 10.—The following officers shall be employed to manage the affairs of the association, and shall be elected every year at the general meeting:—

1. A Director of the Association.
2. A Manager.
3. Five members of Committees.
4. Clerks.

Art. 11.—The Director and the Committee-men shall receive no salary. But their travelling expenses shall be paid if they have to travel on the business of the Association.

Art. 12.—Travelling Commissioners, the Manager, and the clerks shall receive salaries, the amount of which shall be determined by a general meeting.

Art. 13.—The case of Commissioners who while they are abroad, accomplish something specially praiseworthy, or who work without salaries, shall be considered at the general meeting, and their deeds shall be published in the newspapers, a letter of thanks, being also sent to them from the head office.—*Japan Weekly Mail*, Oct. 10th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*)

London, Oct. 7th.

ANNATTO.—Nineteen bags seed, of fair quality, from Cotoibo, are held for 24s, an offer 24s was refused. A small parcel of roll annatto, good bright, but rather dry Paris, was shown—11s is the price.

CINCHONA.—The total quantity of bark sold to manufacturers at the London auctions, from the beginning of this year up to October 6th, is estimated to equal 84,915 kilos sulphate of quinine, and that sold to manufacturers at the Amsterdam auctions, from the beginning of the year up to (and including) October 8th, to equal 95,658 kilos. At the last Amsterdam auctions the following quantities of bark were bought by the principal purchasers:—the Akerbach factory 122,000 kilos; the Amsterdam factory 96,400 kilos; the Brunswick factory 76,800 kilos; the Philadelphia factory 57,400 kilos; the Paris factory 30,000 kilos; the Stuttgart and Frankfort-on-Main works 21,800 kilos; and Messrs. Howards & Sons 5,200 kilos. Details concerning the Amsterdam cinchona auctions of last Thursday show that the manufacturing barks sold at an average unit of 581 cents per half kilo. Altogether the equivalent 18,351 kilos quinine sulphate in the bark was sold to manufacturers at the following prices:—1,205 kilos at 5 cents 5,115 kilos at 5½ cents, 6,810 kilos at 6 cents, 1,683 kilos at 6½ cents, and 237 kilos at 7 cents. For pharmaceutical barks the demand was exceedingly slack. From the Government plantations only short quills were offered, and there were only a few lots thin long quills from private estates. Among the parcels sold there were 118 bales analysing between 7 and 8 per cent, and two lots yielding over 8 per cent. These two last sold as follows:—107 bales Ledger stem bark, broken quill at 64d to 73d per lb; 17 bales Ledger root at 8d per lb. The lowest parcel of bark offered at the sale consisted of six mats *Succubra*, analysing 6.55 per cent. This sold at the rate of 4d per lb. The exports of cinchona from Java for the first two months of the season (July and September) are said to have been 2,000,000 Amst. lb, against 1,560,000 Amst. lb and 1,400,000 Amst. lb respectively, for the first two months of the 1890 and 1889 seasons.

TRANSACTIONS in jute fell off to a remarkable extent in Tippera last year. The Commissioner of the Chittagong Division writes that the price of jute in Tippera fell from Rs.8 to Rs.3 per maund, and that, in consequence, the cultivators were reported in some places to have left the jute uncut. No actual distress was felt, though the extraordinary fall is said to have largely affected the revenue administration of the district.—*Calcutta Englishman*.

THE INDIGO CROP.

SIMLA, Oct. 31.—The final report in the indigo crop of 1891 in the North-West Provinces states that the total area, recorded by Patwaris under Indigo is 201,000 acres against 251,000 last year, and the area returned by the Canal Department as receiving irrigation is 1,85,000 against 2,28,000 in the preceding year. The Zamindars estimate the crop area at 17 per cent less than last year. The plants suffered from locusts and drought in June and July and from excessive rains in August. The condition of crops is reckoned as follows: 100 presenting full average, Gangatic Doab 45, Benares and Gorakpur Divisions 55, and Rohilkund and Oudh 50. The outturn of the dye is expected to be five per cent less than last year.—*Madras Mail.*

THE COTTON CROP OF 1891.

SIMLA, Oct. 31.—The second general memorandum on the cotton crop of 1891 runs:—The second reports on the cotton crops of the year confirm the estimates already published of a serious deficiency in the area sown owing to unequally late arrival of monsoon rains, which were not generally established till the end of July, by which time the season for sowing the early crop was almost over. Further injury has since been caused in the Central and Northern Provinces by excessive rain in August and September, in the Southern Presidencies by scanty and untimely falls, and in the West by locusts. In the important cotton producing Provinces of Bombay, where from 5 to 5½ million acres are ordinarily cultivated with cotton, the area sown to dates does not, so far as present information goes, much exceed four million acres, of which 1,179,000 acres in area are under the early, and 2,888,000 under the late varieties. There has, however, been no material decrease in Berar. The deficiency first reported having apparently been made up by later sowings. The area in this Province, which stands next in importance to Bombay as a producer of the staple, is reported about 2,250,000 acres. In the Central Provinces the area devoted to cotton ranges from half a million to 700,000 acres. The sowings were retarded by late arrival of rains, and the plants have been much damaged by excessive moisture and floods during August and September, when they require to be weeded. The crop is not likely to be more than 60 per cent. of an average one. Similar causes have affected the area in the North-Western Provinces and Oudh, where it is estimated at 35 per cent. less than the normal (about 1,700,000 acres). In Punjab further sowings anticipated have not taken place, and the area remains at 600,000 acres or some 30 per cent. below that of the previous year. In Madras the sowings of both early and late crops are under 400,000 acres or little more than half the normal area. Taking six reporting Provinces together, the total area is approximately 9 million acres against an average of 12 millions. The condition of the early crop in Bombay is generally speaking, fair, but in parts of Khandeish the crop has suffered from excessive rain, which has also damaged the late crop in Guzerat. In the Carnatic the late crop is very backward for want of sufficient moisture, and only 27 per cent. of the average area has been sown. The Sindh crop has suffered from locusts and unfavourable inundations by the Indus. In Berar the condition is on the whole satisfactory, but the Madras crop, though somewhat improved by recent rains, is likely to be very poor. In the Central Provinces the outturn will fall from 60 to 40 per cent. below the average, while another poor harvest is expected in the Punjab, where locusts have seriously injured the plants.—*Ibid.*

CEYLON AT THE CHICAGO EXHIBITION.

The Secretary of the Planters' Association sends us for publication the following copy of a letter addressed to non-subscribers to the Tea Fund by the Chairman inviting subscriptions towards a special "Chicago Exhibition Fund."

DEAR SIR,—As you are not a subscriber to the Tea Fund I venture to lay before you the position of the Subscribers to that Fund, and to ask your assistance towards raising a Special Fund for pushing Ceylon Tea in America at the Chicago Exhibition.

There is no doubt that the present position of Ceylon Tea, and the fact that it is now so largely consumed at home and is fast finding its way into the Australian and some of the Continental Markets, is very largely due to the action of the Standing Committee of the Tea Fund, during the past few years; and no impartial observer, whatever views he may take of the action of the Committee at different times, can fail to admit this.

The erection of the Tea Kiosk in Colombo, and the lease of the building to the newly formed Ceylon Tea Co., Limited, has raised much opposition, much of it I consider of an interested character, since there is every prospect of the company becoming a successful agency for advertising and selling Ceylon Tea, and therefore bound to conflict to some extent with already existing interests.

As several incorrect and misleading statements have been lately published on this matter I would bring to your notice.

(1.) That the Planters' Association or its Standing Committee of the Tea Fund have no legal power to trade by working the Kiosk.

(2.) That the New Tea Company was started mainly with a view to relieve this difficulty.

(3.) That the Kiosk and its hasment have been leased to the Tea Company and the Syndicate Boat Company respectively with the consent of the Government (whose consent was necessary under the terms of the original lease.)

(4.) That the annual rent to be paid is R1,000 in all, equal to nearly 7 per cent interest on the total cost of the Kiosk and its furniture, viz. R15,000; so that the subscribers to the Tea Fund obtain nearly 7 per cent. on this investment, plus the free advertising of Ceylon Tea which must necessarily be effected through the Kiosk in any event.

The main object of the Committee at the present time is to take advantage of the Chicago Exhibition for pushing our teas in America.

To do this well and thoroughly will be a costly undertaking, and no effort should be spared to make it a success.

The Ceylon Government have promised R50,000 towards a Ceylon Court, and the Tea Fund Committee have voted R30,000 for the Ceylon Tea interests; but much more than this will be required.

I appeal to you not to leave it entirely to others to supply the necessary funds: I cannot but feel that those who have subscribed to the Tea Fund throughout have been somewhat ungenerously treated by those who do not subscribe, since the benefits reaped—and of these there can be no doubt—are reaped by non-subscribers equally with subscribers.

I asked you therefore with confidence to contribute a special donation towards the Chicago Exhibition Fund, and I would suggest for your consideration that this should be based on the ratio $\frac{1}{2}$ of a cent per lb. made tea for the current year.

It may be and indeed is as a rule impossible for the Committee to carry out the views of each individual subscriber to the Tea Fund; but I unhesitatingly assure you that all views have received and will receive full consideration at the hands of the Committee, and the views ultimately adopted in any case are necessarily those which the majority of the members consider most likely to attain the objects we all have in common.

I trust you will give a liberal response to my appeal, and will be good enough to favour me in any case with an early reply to the Secretary of Association, Kandy.—I am, dear sir, yours very faithfully, GILES F. WALKER, Chairman Planters' Association of Ceylon.

THE AGRICULTURAL PRODUCTS OF MADAGASCAR.

M. d'Anthonard, Chancellor of the French Residency at Antananarivo, has recently made to the French Government an interesting report upon the economic condition of Madagascar, a translation of which appears in the *Journal of the Society of Arts* for July 31st, and is reproduced in *Science*. In that portion of the report which is devoted to the consideration of the agricultural development of the island, it is stated that the chief agricultural products are sugar, coffee, cocoa, vanilla, cloves, rice, potatoes, tamarinds, indigo, wine, oranges and lemons. Sugar cultivation was first commenced in 1842; and two factories were erected at Managany. Good results were obtained in the first two years; but, during the third year, riots took place among the workmen, and the plantations were destroyed. In 1878 three new factories were established in the neighborhood of Tamatave; and in 1883, on the outbreak of hostilities between France and Madagascar, they were in full working. At the present time, the number of plantations round Tamatave has greatly increased; and also in the south, towards Mahanero and Vatomandry.

Coffee trees grow well in Madagascar, and it is stated to be by no means an uncommon thing to see plantations that are 45 years old, and even more, which have never ceased to yield good results. A large plantation has recently been established in Imerina by a French company; it extends over an area of about 800 acres. Great results are expected from the development of the coffee industry of Madagascar, as the difference between the cost price and the price it realizes in European markets allows of a considerable outlay on its cultivation and then leaves a large margin of profit.

The cocoa tree was introduced into Madagascar by means of seeds brought from the Mauritius and Reunion, in which places it has been for a long time a source of considerable revenue. The tree commences to bear at the end of three years, but it is only in full bearing at the end of the fifth year, and it so remains for thirty years. The cost of cultivation is less than that of coffee. The cocoa tree is chiefly cultivated in the Eastern portion of the island, and it is only of recent years that the industry has assumed any importance. In 1883 there were not less than 5,000 or 6,000 trees round the coast, and these were abandoned when the war broke out. After the war it was found that, notwithstanding the want of care and attention, the young cocoa plantations were still flourishing, and this phenomenon encouraged the planters to pay greater attention to the development of this cultivation. This development dates from the year 1888. Like cocoa, vanilla is one of the agricultural products which has a great future before it in Madagascar, and its cultivation is largely engaged in, in Vatomandry, Malauro, and Mahela. Vanilla plants commence to yield after the third year, and in the fourth they are in full bearing.

The cultivation of rice, which is well developed in the interior of the island, is very much less so on the coasts, where the land is more fertile. While in the latter districts the inhabitants are content to sow the seed without any preparation of the ground but the burning of the trees and grass, the Hovs and the Betsileos, having a much poorer soil, take more pain to develop and perfect their system of cultivation. In some instances, for example, in the neighbourhood of Antananarivo, they have transformed immense tracts of marsh land into rice plantations. The plains of Betsimitatatra, towards the west of the capital, which are watered by the Ikopa, Andromba and Simony rivers, now the centre of the rice production in Imerina, have been drained and cleared, irrigating canals have been pierced, and everything has been done to favour the production. Similar well cultivated plains are found in great number to the south of Imerina and in Betsileo. In the mountain districts the rice grounds are laid out in terraces on the slopes of the mountains and hills, and rice grounds are frequently met with rising tier upon tier up to the very summit of the high mountains.

Potatoes are largely cultivated in the districts round Ankaratra. Tamarinds are common all over the west coast, where the plants form immense thickets. The Sakalaves distill spirits from the fruit. Peaches grow almost wild all over the island, and the same may be said of the indigo plant.

As regards vines, there are different species in Madagascar. One variety was originally imported from Portugal; another variety appears to be indigenous to the soil. In Imerina attempts have been made in recent years to acclimatize vines, but some which were brought from Bordeaux have not succeeded. On the other hand, American vines have prospered, and the grapes are not of a superior kind, and the wine made from them is very poor. Orange and lemon trees are found all over the island, growing in a wild state on the coasts, and cultivated in the interior.—*American Grocer*.

TEA IN JAPAN.

There is no more curious incident in the history of the food supplies of the world than the great and sudden change that has occurred in countries as the home of tea. It is but a few years, and easily within the memory of all of us, when the mention of tea at once brought to mind visions of the celestial empire, and cultivators in picturesque smocks and long gaiters, and the fact that on a few hills in Northern and Southern India and in the steamy lowlands of Assam, Englishmen could be found who devoted their time and attention to the cultivation of this shrub regarded almost as a freak of nature, while the men themselves were looked on in much the same light as farmers, who pass their lives growing fruit-trees for the sole purpose of converting their yield into jam. But the Chinaman with the yoke and hucketa is now almost defunct in the imagination of the British public, and Ceylon and India stand out prominently as the countries from which the breakfast tables of the Western world are to be supplied with that leaf, so long considered as a luxury only accessible to the very rich and wealthy, but now a necessity for the mechanic and labourer in fact no working-man who aspires to the smallest shew of comfort would be content without his cup of tea. One of the effects of this sudden change in the cultivation of tea has been to prove that there is no particular difficulty attached to its growth and manufacture, and so long as a land possesses soil that is fairly productive, and a climate which is fairly moist, the shrub will flourish and crop well. Consequently we find throughout tropical lands a general desire to participate in the profits believed to exist in its cultivation, and Java, Japan, Borneo and the Fiji Islands are all converting their jungle into tea-gardens. The result naturally is a extreme risk of over-production, which will, of course be felt first in those countries whose labour supply is not perfect but expensive, and which do not possess the best facilities for cheap manufacture and cheap transport to the markets of the West.

A British Consul in his report of the trade of Hiogo and Osaka has given recently an interesting account of the cultivation and the trade of tea in Japan, where it has only been recently taken up. There is not much fear of this country ever becoming a very serious rival to Ceylon and India in the tea-markets of Europe, but it is said that the United States have shown a marked preference for the Japanese leaf, which is likely to retard the sales of British-grown kinds in that country. Mr. Consul Eslio in his report states that, owing to the incessant rains having forced the growth of the leaf, the quality of the first crop proved disappointing, and had it not been for the effect which the marked advance in silver had on exchange (higher rates preventing later teas from being laid down as cheaply), there can be little doubt that the season would have proved an unsatisfactory one to shippers. As supplies increased, prices gradually declined, until they showed a drop of from two to three dollars on the earlier prices for the better descriptions of leaf, and

one dollar for common to medium grades, the latter being throughout the season most in request. The second crop was more satisfactory in quality than the first, and towards the middle of July some slight concessions on the part of holders, coupled with encouraging advices from the consuming markets, led to considerable business, the lower grades again meeting with most inquiry. Increased firmness on the part of sellers followed, supplies being also withheld with a view to forcing up prices, and as the season progressed, a marked deterioration both in the quantity and quality became noticeable. A decline of 50 per cent. in Suez freights materially assisted the Japanese in maintaining values, notwithstanding the high rates of exchange then ruling, and business continued on about the same basis until the end of September, holders taking advantage of every opportunity to raise prices until they reached such a point as to render further buying unremunerative, especially in view of the inferior selection and paucity of stocks, which by this time had dwindled down to some 270,000 lb. The financial crisis in Europe, in the fall of the year, put a sudden stop to business in the United States of America, the effect of which was quickly felt in Japan and the season was virtually closed by the end of October, although, as usual, a few desultory purchases continued to be made, amounting to some 530,000 lb. The total business for the season was 21,639,431 lb., that for 1889 having been 18,245,735 lb.

An increase in exports of 3½ million pounds is by no means to be overlooked more especially in an advanced country like Japan, which will probably import all the latest machinery, when she realises that by cheap and improved methods of manufacture she can obtain a share of the custom of the world. The flavour of the Japan leaf is said to be more delicate than Ceylon or Indian, and nearer in approach to China. As we know, in England the popular taste has turned, and the tea-drinking public demands stronger and more pungent liquors than the Pekoes and Congous of Hankow and Formosa supply. But both in Russia and the United States—two great consumers—the delicacy of the latter is still appreciated, and it appears as if many years must elapse before our British-grown leaf is liked, nor will the job be easier if Japan can supply China grades at Indian prices. As we have constantly urged in these columns, it behoves the whole tea-planting community to spare no labour nor care in the cultivation and the manufacture of leaf, and to flood the markets with low grades is to undergo the very great risk of throwing away the advantage now gained. Already a warning note has been sounded against the ill-effects of tea, in the argument that has been waged over alcoholic drinks. Excess of tannin undoubtedly is as detrimental to the human frame as alcohol, and it is possible to turn out of a tea factory leaf an infusion of which is hardly a whit less poisonous than the decoctions of grape that find their way out of France under the name of brandy. [The comparison is most unjust to tea. Strength depends on tannin, but an infusion properly made contains only an innocent proportion of this ingredient.—Ed. T. A.]

The increased activity of tea cultivation in Japan should bring home to planters in this country the necessity of keeping up the quality and not sacrificing everything to a perfidious pride in output of pounds per acre. By putting together the London brokers' reports on Travancore tea and the last accounts which our Peermad correspondent sent us we are afraid there is a tendency to err in this way down south, for until a short while ago Travancore tea commanded as good value as Ceylon, whereas for some weeks past now its average is 20 per cent. lower than that island, and from 30 to 35 per cent. below Assam.—*Madras Times*.

The Auerbach quinine factory have obtained a contract from the Dutch Government for the supply of 500 kilos. (about 16,000 oz.) of sulphate of quinine standing the test of the new Dutch Pharmacopœia.—*Chemist and Druggist*.

THE CHINA TEA TRADE IRREVOCABLY DOOMED.—The Tea Report of 23rd Oct. of Messrs. Purdon & Co. of Shanghai says:—

Disastrous sales are still being wired out, chiefly teas on native account, the percentage of loss remaining as high as 50 per cent; these losses should prove a lesson to the Chinese and show them that their teas are not wanted. Advices from Russia are very discouraging, the fall in the rouble exchange and the internal distress having a very bad effect on trade in general. The large quantity of 'high cost' teas shipped to Russia last season will be sufficient to keep that market stocked for fully two years, and as it is very apparent that the London market only require 'tea for price,' next season's prospect of a fine crop is very remote. Unless the export duty and the lekin duties are reduced, the China tea trade is irrevocably doomed, and it behoves the authorities to act promptly and prevent what will otherwise prove to be a national disaster.

During the first six months of the current year the trade demand ran on common teas, on the 26th June Pekoe Souchongs realising sevenpence-halfpenny to ninepence per pound whilst Broken and Orange Pekoes sold for ninepence-farthing to a shilling per pound. Of course, a few of the finest marks sold at fancy prices, as they always do. On the first arrivals of the South West Monsoon teas, which are always inferior owing to the difficulty of manufacturing tea in wet weather, the trade demand turned round to the finer descriptions, and common kinds are now unduly depressed and neglected. Whilst Pekoe Souchongs have given way quite twopence per pound, Broken and Orange Pekoes and the better classes generally have advanced from twopence to fourpence per pound. Of course, as there is not a supply of these to meet a monthly demand of five and a-quarter million pounds, the improving quality of the recent arrivals will soon begin to attract attention, for after all it is the common teas that furnish the supply of the masses. But without adequate tasting they have not a fair chance.—*Financial Times*.

CEYLON WOMEN AND CEYLON TEA.—Mr. R. E. Pinco sends us a copy of *Frank Leslie's Illustrated Paper*, containing the portraits of "A Cingalese Girl" and "A Tamil Girl." They are both good-looking, but the "Cingalese" girl is evidently a Tamil. The following letterpress accompanies the illustration:—

The earliest notice of Ceylon is probably contained in the Hindoo poem "Râmâyana." The tradition handed down that Buddha traversed Ceylon, leaving his foot-print on Adams Peak, cannot be vouched for, but is believed by all Buddhists. The antiquity of Ceylon reaches back to 543 B.C. England, in 1793, made Ceylon a crown colony. It is one of the garden spots of the world, and contains about 25,000 square miles, or 16,233,000 acres. It is especially celebrated for its clove-haunts; and its valuable gems, viz., sapphires, rubies, cat's-eyes, alexandrites, and its most exquisite pearls help to add to the charms of the fair sex all over the civilized world. Moreover, it produces—according to the English, who are considered the best judges—the most delightfully flavored tea known and the export of which rose from twenty-three pounds in 1873 to about 54,000,000 pounds in 1890. The present population (composed of a few Europeans, but chiefly of Tamils, Moors, Cingalese, Malays, etc.) is about 3,000,000, and Colombo, the capital, contains about 120,000 inhabitants. Like the city of the great World's Fair, a single product helps to make its citizens not only wealthy, but important. Chicago boasts its pork, Ceylon its tea. No business interview or political colloquy ever takes place on the island in which Ceylon tea is not a necessary factor. The splendid breakwater, which was built at a cost of \$1,000,000, gives the stranger within its gates a sense of absolute security upon reaching the harbor of Colombo. We are indebted to Mr. S. Elwood May, the president of the Ceylon Planters' Tea Company, of New York, London, and Colombo, for the use of the accompanying illustrations.

GEMMING AND MINING COMPANY
OF CEYLON.

LONDON, NOV. 23.

There is no doubt that the result to the last year's working of the Gemming and Mining Company of Ceylon has been anything but satisfactory. The extract from the *Investors' Guardian* given below reveals this very fully, though the paragraph is written in a tone which shows but little acquaintance by its author of the real facts with regard to the prospects with which the company was started; for we all know that the precious stones are there, even if the steps taken by the directors have failed to secure them for their shareholders. The current talk here is that gems of a fine quality and size were never so abundant in Colombo as they are at the present time; and it is the generally expressed opinion that the operations of the company account for this, that these stones have been obtained by its working, but that, as Mr. Streeter predicted to me would be the case, they do not get beyond the native labourers who have found them while employed in the company's pits. Unless some means can be taken to guard against such thefts, it is much to be feared gemming on a large scale will never prove remunerative in Ceylon. We hope, however, that the affairs of the company may be retrieved during the current year by its output of plumbago.

THE GEMMING AND MINING COMPANY OF CEYLON.—This Company cannot be congratulated at the result of its operations during the past year. The Kimberley compound system is evidently not in vogue in Ceylon, for the good stones found by its native employes were retained by them for their private uses, and they simply handed to the company those which possessed no mercantile value. The consequence is that the Company has lost during the year £3,453 18s 1d by its operations, this including the cost of the London offices and directors' fees amounting to some £860. The main hope of the chairman now seems to rest, not on the precious stones, but on the deposits of plumbago, which they have discovered on their property. We are told by chemists that the diamond and plumbago have an identical chemical composition, and this knowledge may somewhat console the shareholders for its substitution, although they may fairly argue that they subscribed on the testimony of the experts that the carbon on their property was in the form of precious stones, and not in that of blacklead.—*London Cor.*

THE ADVANCE OF BRITISH-GROWN
TEA.

From the monthly circular on the tea market, issued by Messrs. Gow, Wilson, and Stanton we observe that the appreciation of the Ceylon leaf by British consumers is increasing as fast as the production. For the period from the beginning of June to the end of September—the four heaviest months of the year—the imports have amounted to twenty-three million pounds, against fifteen and a-half million pounds in the corresponding months of 1890, and eleven million pounds in 1889. The figure is a heavy one, being greater than the imports of the Indian product in the same period only two years ago, but, instead of creating a plethora, it has been taken almost entirely off the market, the deliveries coming to twenty-one and a-third million pounds. The addition to stock is, therefore, small, and there is the less danger of a glut from the fact that during the ensuing two months there is a probability of a deficiency in the supply, as the shipments are estimated at only four million pounds per month. This does not, however, imply any falling off in the production of Ceylon. From what we can learn with reference to the future yield, we think it likely the total will go on mounting for years to come in the

ratio of the past—that is to say, an increase of from eight to ten million pounds per annum may be looked forward to as practically assured. But if we judge the future consumption also by past experience, there should be no cause to apprehend that over-supply which Ceylon's legions of eucemics predict.

As the importation of Indian and Ceylon teas increases in volume, the Chinese leaf is being displaced to make room for the British-grown produce, and from present appearances it would appear that the Flowery Land will be elbowed out of the way altogether in the course of another ten or fifteen years. In 1879 the Celestials sent us no less than one hundred and twenty-six million pounds. Ceylon had not been heard of as a tea producer, and the Indian contribution was only thirty-four million pounds, having grown in the preceding fifteen years from hardly three millions. Since then both Ceylon and India have been forging ahead, and China has been on the down grade, the complete reversal of the market being one of the wonders of modern commerce. A glance at the statistics of the past six years will surprise many of our readers, we imagine, for the transformation is quite sensational in character. The home consumption in those years was as follows, the figures representing thousands of pounds* :—

	1885.	1886.	1887.	1888.	1889.	1890.
India ..	65,673	68,420	83,112	86,210	96,000	101,962
Ceylon ..	3,217	6,245	9,941	18,553	28,500	34,517
China, &c.	113,514	101,226	99,505	80,653	61,100	57,530

(1,000 lb.)..182,409 178,891 183,561 185,416 185,600 194,009

It will be seen that the Chinese leaf has not fallen away because of any reduction in the consumption of tea, which has materially increased within that period, but has declined inversely with the development of the East Indian industry.

But although there is no doubt as to the headway being made in Great Britain by the British-grown leaf, the apostles of India and Ceylon are not satisfied. It is true that during the five years 1885-1889 the United Kingdom consumed one hundred and eighty-three million pounds of tea, but in the same period the United States drank seventy-nine millions, Russia seventy millions and a-half, the Australian Colonies twenty-one millions and a-half and Canada nearly nineteen millions. There is, therefore, a much larger world yet to conquer, and one remarkable and satisfactory feature in the position of Ceylon tea is the very kindly manner in which other countries are taking to its use, the British colonies being especially prominent in this respect. We have before us returns of the exports from Ceylon to other countries for the first eight months of the current year, and comparing these with the returns for the corresponding period of last year, we find an increase of seventy-two per cent. As these returns are of considerable interest, we give them in full. The respective shipments were as follows :—

	1891	1890
	lb.	lb.
Austria	50,150	1,270
France	9,300	612
Germany	69,300	14,200
Russia	11,250	15
India	270,650	87,600
Australia	2,211,500	1,413,000
America	139,000	119,300
Africa	56,650	35,100
Obina	87,900	33,200
Mauritius	34,300	140
	<u>2,940,400</u>	<u>1,704,437</u>

It is disappointing that the Yankees took only 139,000 pounds, though a large public company was formed in the States with a great flourish of trumpets to promote the consumption of Ceylon tea. It will be noticed, however, that even the Chinese themselves have begun to sip the rival nectar.—*Financial Times.*

* More simply stated, the figures or ciphers for millions are omitted.—Ed. T. A.

THE LOCAL MANUFACTURE OF QUININE.

Some interest has been aroused amongst Indian planters by the announcement that growers of cinchona in Java intend to establish a quinine factory, and to make quinine on the spot, instead of exporting their bark to Europe. To the planter the advantages of such a procedure would be very great. The objection to it would come from those having vested interests in the present course of business; at any rate, much support could not be looked for from this quarter. Large Companies or private firms with their head quarters in London would probably not be very enthusiastic about the scheme. But it is well worth the individual planter's while to look into the matter for himself. A few figures will prove this. Suppose a planter to have had 12,000 lb. of Suacirabra at the end of last year, which he could sell in the London market at 2d per lb., or for £100. As the London buyer takes the cost of extracting the quinine into consideration, the local factory could afford to pay the same price. The cost of harvesting and transport to the port of shipment is about 4d; so the planter would have had the equivalent of £76 clear if he had sold his bark in India. But what he really got was much less. The first deduction was for baling and shipping at £45 per ton; this amounted to £225 (say £16). The cost of freight to London, insurance, dock dues, rent for warehousing, analysis, brokerage and commission usually comes to 20 per cent on the sale value of the consignment. Sometimes it is rather more. But putting it at 20 per cent, the account stands thus:—

Value of bark	...	£100
Less cost of harvesting	...	£25 0 0
"Coast charges," (Baling etc.)		16 0 0
London charges (20 per cent)		20 0 0
Total deductions		£66 0 0

In addition to this the planter had to wait for his money for about four or five months. These figures speak for themselves. The charge for baling and shipping is to be reduced this season to about £34 per ton, but there is no sign of similar movement among the London brokers. Shipping bark to London at present prices, if there is a chance of getting the quinine extracted in this country, seems almost as great an extravagance as it would be to ship the quartz from the Mysore mines instead of crushing it on the spot.—*M. Mail*, Oct. 26th.

[Our readers can compare this statement with the adverse opinion regarding local manufacture formed by Mr. John Ferguson after visiting the Waldhof quinine works.—*Ed. T. A.*]

A CORNER IN COFFEE.

We have frequently remarked that the coffee bean is often regarded as little better than a gambling counter, and that the manipulations of clever commercial gentlemen have a greater influence on the value of coffee than the reported estimate of a Brazilian crop of ten million bags. We need not apologise for quoting in full this article which appeared in a recent issue of the *Financial News*:—"Not only the Mincing-lane market but the coffee markets of Havre, Hamburg, and Antwerp have lately been disturbed by a clique who tried their very best to corner coffee. The ringleader in this combination was the German partner of a New York coffee house, which of late years has taken a front rank in the American coffee trade, but which, also, has acquired an unenviable notoriety for being connected with cornering operations. Thus in June, 1888, this house in conjunction with another firm in the same city, so manipulated the New York market that they forced the price of coffee for delivery in June that year up from 12-80 cents per lb. to 20-50 cents per lb. in one day. This rig led to a change in the management of the exchange, from which the cornerers were

excluded, and later on new rules were adopted which made it much more difficult for any single firm or combination to manipulate the coffee market in New York. So little did these new rules please the firm in question that in August, 1890 they issued a circular, in which they ostentatiously intimated that they had concluded to withdraw from the commission option business in coffee on and after December 31st, 1890. They did not, however, explicitly state that they intended to discontinue option business on their own account on the New York Exchange; but this may, perhaps, be inferred from another paragraph in the same circular, where they state that: "We shall continue our regular activity in the importation of coffee, and we also expect to deal more or less on such coffee exchanges where we think buyers and sellers will be treated on a parity, and where we can secure a contract that will represent a merchantable average grade of coffee, such as is required for consumption here or in Europe." During some considerable time past the German partner of this firm has been staying for long intervals in Europe, and there is no doubt that his influence has been felt in all the European term markets chiefly, however, in those of Havre and Hamburg. In July last this smart operator conceived the brilliant idea of cornering coffee in Europe in face of the largest coffee crop ever marketed in Brazil. A more madcap scheme, a more unbusiness-like proceeding, could hardly be imagined. Warnings of the utter rottenness of such an operation were not wanting; but they were completely disregarded by this gambler, intoxicated with past success. He was determined to corner "September," and, after September, he would corner October, and after October, he would put up the price of the December option. After that let the deluge come, he would take good care to be on the hill-top then. In order to play this little game out it was necessary to have confederates. In Antwerp, as in Hamburg, he found them ready to hand; but London had also to be drawn into the whirlpool. Hence a visit to London was decided on, and so timed as to enable him to meet his co-operator in the New York corner of June, 1888. These two worthies sat in conclave in Mincing-lane in July last, and concerted the scheme which, hy-and-hy, was to be carried out by the conspirators in each port. Unfortunately, two firms in London were induced to join this miserable combination. Thus the hall was set rolling. The September option in Havre was day by day pushed up; other markets followed suit, as the clique continued to buy and drive prices higher, no matter whether receipts in Brazil came large or small—in fact, the larger the receipts the more they were prepared to pay for options. The rig was palpable, and had a certain amount of success because of the disinclination of merchants to sell "September" owing to the small stocks in Europe and the generally strong statistical position at that time of the article. Then the October position was taken in hand, and prices of this delivery were also advanced by leaps and bounds, until at last merchants felt that the clique had overstepped the mark, and offered freely coffee for shipment from Brazil at lower and lower prices, until the rig utterly collapsed and left the clique with a large stock of high-priced coffee. The whole affair has been a complete fiasco, and it has involved the clique in tremendous losses. One of the young London firms who joined it has been in dire distress, while the other firm, who worked the oracle for the clique in Mincing-lane, has lost heavily in money and still more heavily in popularity and reputation. An old and most respectable firm in Antwerp has weathered the storm only with great sacrifices, but comes out with an impaired name. From first to last it was a disgraceful business, reflecting the utmost discredit upon everyone engaged in it. In less than six weeks coffee has declined from 15s to 20s per cwt. in the term market here, and there is every probability that the downward movement will make further progress, since confidence has been completely shaken by the operations of the riggers."

We are glad to find our London contemporary speaking so strongly on the subject. Disgraceful is the only

epithet applicable to such transactions, be the counters shares or real estate, but when it is with produce, and produce which is almost a necessity of life, it is well nigh impossible to employ too strong terms in commenting on such dealings. Planters may congratulate themselves that the corvée collapsed when it did, for some time will have elapsed before their crops reach the London market, and confidence amongst the dealers will have been partly restored. One of the most noticeable features of the recent collapse was the way in which dealers held off, though it was well-known that the trade was poorly supplied, and for some months previously had been carrying on a hand-to-mouth business. So soon as confidence is restored, we can anticipate a firmer tone in the markets and as there are absolutely no stocks of the superior grades of coffee which the Southern Indian plantations produce, the sale-rooms will probably witness keen competition at the beginning of the coming year.—*Madras Times*.

NOTES ON PRODUCE AND FINANCE.

AN OUTCRY AGAINST TEA.—It is evident that a few fussy people whose sisters, cousins, and aunts have at some time or other suffered from "nerves," which they have been told is the result of too much tea, are trying to create a panic in the public mind on the subject. It is quite the proper thing in advanced female circles to sneer at tea as utterly unsuited to the modern Minerva. All cultured women should abhor tea. One of the journals written especially for ladies has called attention to the enormities of tea-drinking by ladies—excesses which, in the opinion of the enemies of the tea-pot, are grievously aggravated when the cup which cheers but not inebriates is accompanied by buns, scones, short-bread, and especially by the dark and dyspeptic plumcake. The foes of tea maintain that there is an utter lack of dignity in the spectacle of a levy of ladies sitting at marble tables munching indigestion-breeding plumcake and sipping equally unwholesome tea. Mrs. Fawcett is quoted as an authority on this matter, and in the article referred to, her opinion, real or alleged, is quoted against the pernicious habit.

TEA AND THE KINDRED CURSE.—But the opposition to tea drinking does not come from the ladies alone. In the *Daily News* of Tuesday last we find the following:—"It is not ladies only who are slaves of the teapot. According to a correspondent of *The Granta*, the fascinating beverage—as Dr. Johnson called it—is working havoc with the nerves and brains of Cambridge undergraduates. They start the day by drinking large quantities—the 'kindred curse' coffee is occasionally substituted, but it is pretty much the same. In the afternoon they have tea again, and not once only, but many times. This witness has himself partaken of five teas in one afternoon. After Hall, more 'slops,' and then, perhaps about eleven at night if the vice has made sufficient progress, an abandoned man will brew more tea, and eventually retire to rest 'a limp, miserable, tea-sodden wretch.' An instance is excited of an excellent Rugby player who came to Cambridge with a good chance of 'obtaining his hino' in his second season. But before that time a marked and painful change had set in. His digestion was gone, his hum—once the steadiest—trembled pitifully. People said he had given way to drink.' He had only given way to tea. 'Who,' asks this ardent reformer, 'will be the first to join the Light Blue Ribbon Army with a pledge against—Tea?'"

AN ABSURD POSITION.—The position seems to be this: Simply because a few people have made themselves slaves to the custom of afternoon tea, and have carried it to excess in every way, a few more equally absurd people are crying out that all the evils in the universe arise from tea drinking. Because Mrs. Mauvelro doses her friends with tea and cake until they become ill, or Mrs. Gamp stews her tea until she is poisoned, therefore tea is generally injurious. All this is childish. As the *Daily Telegraph* remarks, at the close of a recent article on tea drinking:—"As regards

England, we wholly fail to see that the consumption of tea is immoderate, that it has injured the health of the community, or that it has diminished the native grace and dignity of Englishwomen. Envy, malice, and all uncharitableness are much more conducive to indigestion than 5 o'clock tea." If tea does not agree with some people they should not drink it. There are plenty with whom it does agree, and these are not likely to give it up because a small minority rail against it.

AN OLD STORY.—But in addition to the strong-minded ladies who abuse tea, and the weak-nerved students who say ditto, tea has enemies more subtle, witness the following paragraph taken from the *Echo*:—"Thus Sir Edward Clarke:—'Tea to houseful should be, first of all, black Chiua tea—the Indian tea which is being cultivated has become so powerful in its effects upon the nervous system that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of tea intoxication, and produces a form of nerve disturbance which is most painful to witness.' If the reference in the above paragraph is to Sir Edward Clarke, the Solicitor-General, it would be interesting to know when that learned gentleman became a tea expert. If the paragraph is meant to refer to Sir Andrew Clark, it would be useful to learn how the celebrated physician obtained his information. If the paragraph is inserted merely by some friend of the Chinese importer who keeps a "hoyey man" in his advertisement department, it is merely an instance of the vast resources of civilisation, and should be taken warily and with much sarcasm. This attack on tea drinking has, however, to be reckoned with, and it would be useful if some scientific opinion were taken on the subject, and the minds of consumers disabused once and for all of the idea that tea drinking in moderation is injurious.

A FORECAST IN TEA.—In an article on the "Tea Trade for 1891," the *Citizen* indulges in prophecy. It says:—"Viewing the ever-increasing acreage in both Indian and Ceylon—and in the latter colony a coffee estate of 300 acres can at a pinch be converted into a tea garden in the space of a single season, so well supplied are the planters with nurseries and skilled labour—we cannot but forecast a gradual reduction in prices as a natural result of increased production. Ceylon alone, when the acreage at present planted comes into full bearing four years hence, will be in a position to swamp the market with tea just as she did first with coffee and then with cinchona. The masses who but five years ago could buy very little tea worth drinking at anything under 2s a pound will soon be able to buy much the same grade of tea at a shilling. It now remains to see what other effects this probable over-production will have. Proprietors of a group of large and paying gardens, fearing, as they do, a fall in prices, will be anxious to realise while their books show handsome profits for a series of years. We have already heard the names of various properties destined for formation into a company, to be registered in London, and which is to be offered to the public at a price estimated to pay 12 per cent on the ordinary shares. At present very few tea companies' shares are officially quoted in the London Stock Exchange, although in Calcutta such securities are dealt in every day. Those that are quoted here pay good dividends and maintain their price quite as well as either breweries or industrial undertakings. Provided an allowance be made for a fall in the price of tea, there is no reason why new planting companies should not prove a suitable and remunerative investment for the public, provided the directors receive the bulk of their remuneration from dividend results. If any such flotations make their appearance this autumn it may be as well if shareholders in the old companies, whose shares are likely to lose rather than to gain ground during 1892, were to consider the advisability of realising with a view to transfer their money to new ventures. The shares of the Assam, the Darjeeling, the Doora Tea, the Jukai Assam and the Jorehaut Tea Companies all command a good premium and pay handsome dividends, and the field is still open for other promising undertaking of a similar nature."

HOP TEA.—The combination of hops with tea seems to find appreciation. The process was fully explained by Mr. A. Scolling (the patentee) at a visit recently paid to the works at Maidstone by the directors of the Hop Tea Foreign and Colonial Syndicate and their friends. The fresh hops are withered by patent machinery, rolled, allowed to ferment for the purpose of modifying the naturally bitter taste, and then dried by the well-known "Sirocco" machine process. It was stated that fifteen patents have been secured, or are being applied for, in all the important countries of Europe—India, New South Wales, New Zealand, Queensland, South Australia, Tasmania, and Victoria. Mr. Scolling states that, although the industry had only been started in September last, they had 2,000 agents in the country, and the demand was greatly on the increase.

LAST WEEK'S TEA SALES.—The *Produce Markets' Review* says:—"There was a diminution in the quantities of Indian tea offered this week, and owing to a well sustained enquiry, prices for most grades are firm, while the finest descriptions in some cases show an advance. The moderate prices and good value to be obtained from 1s downwards, are exemplified by the largely increasing consumption, and as there is no immediate prospect that these grades will rise in value, a further important expansion in the demand is probable. At any rate, the comparative value of Indian teas is favourable in this direction, and as there will probably be a falling off in the supply of the Ceylon growths a little later on, a greater impetus will be given to the use of the former. At a recent meeting the tea brokers agreed to endeavour to regulate the quantity to be offered at the public sales. To make this effectual it will be necessary to allow a reasonable time for sampling and valuing the teas, for it is frequently the case at present that the samples are not ready at the warehouse until the afternoon prior to the sale. If importers would adopt the principle of notifying the catalogues until the teas are actually ready for sampling it would greatly facilitate business, and save much loss of time and labour. At the public sales 32,250 packages were brought forward, including a good assortment of most kinds. The bidding was active and a firm tendency was manifest for all good descriptions, while the downward movement for undesirable sorts continues. Ceylon teas have only been sparingly offered, but as the attention of buyers generally has been more or less monopolised by Indian teas, there has been no corresponding rise in values; indeed, although good to fine teas have maintained late prices, the lower kinds have sold at easier rates. The quality of the teas brought forward, although not quite so good as of late, is fairly satisfactory, a point to be specially borne in mind now that fine Ochna Monings and Ningehows, with which teas Ceylons chiefly compete, are selling at prices hitherto unheard of."

SILVER.—The London silver market was not strengthened by the allotment of Council bills, the minimum price accepted on Wednesday being 3-32d lower than the minimum of last week's allotment, and exchange advices from the East were all unchanged, with a weak tendency as regards Bombay. Quotations for bar silver and Mexican dollars nevertheless rose 1-16d per ounce—namely, to 41 9-16d and 43 5-16d per ounce respectively. The advance was due to an increased enquiry for silver for the Continent, possibly in connection with the supply of 50,000 kilogrammes of bar silver for Coinage into Cuban currency. Outward rates for merchants' bills were not further reduced, having been lowered on Saturday last. Four per Cent. Rupee Paper is quoted at £74½ to £74¾.—*H. and O. Mail.*

ADVANCES TO CULTIVATORS AND THE NON-ALIENABILITY OF LAND.

In Ceylon, as in India, the main causes of poverty, depression and ultimate eviction from land and home of the cultivating classes can be traced more to their own improvidence and inveterate habit of bor-

rowing at excessive interest (in which they are aided by the lenders of money, seed corn and cattle) than by Government exaction in the shape of rent or tax. Occasionally in India the poor ryats, finding themselves no match for the astute money-lenders have risen in desperation and taken the law into their own hands. Hence a very serious insurrection amongst the Santal tribes of Bengal and disturbances elsewhere in India. In the Bombay Presidency the Deccan Ryats Relief Act has been a good many years in operation; and one of its provisions is that, however large the debt of a ryat to a usurer may be, the latter cannot gain possession of the cultivator's land, which is rendered inalienable. Our readers can easily see how such a provision tends to check the tendency to borrow and the willingness to lend. The objection offered is that the restriction lessens the credit of the cultivator. That is just what was intended, because such credit was used to raise money to be spent not on the land but on extravagant birth, marriage and death ceremonies and feasts. Then, to supply the cultivators with legitimate loans land banks, are either in operation or under consideration in India, through whose agency Government would make such advances as were really required by cultivators, at moderate rates of interest. In any case advances are made by the Indian Government under due restrictions. In India, indeed, the question of land indebtedness has assumed so serious an aspect that a Commission has been appointed to deal with the whole subject, at the head of which is Sir O. Crosthwaite, lately Chief Commissioner of Burma. The first business of this Commission will be to enquire into the working of the Deccan Act, with a view to its extension to the whole of the Bombay Presidency. People, childish in their ideas and practices, must be dealt with as children; and in Ceylon, as in India, legislation is required to protect the goiyas against their own improvidence and the wiles of usurers who lend them money, seed or cattle, with the very object in a large number of cases of so loading them with debt that their holdings of land must pass into the hands of the usurious lenders. It is impossible to restrict the rates of interest, or to prevent borrowing by levying heavy duties on mortgages; but it is possible for Government to render native holdings of land inalienable, and in dealing with an oriental people western notions of free trade in property must not be strictly applied.

ECHOES OF SCIENCE.

At a recent meeting of the Académie des Sciences, Paris, an interesting paper was read on the hurricane which has devastated the island of Martinique.

A curious feature of the cyclone was the incessant lightning flashes which accompanied it. They increased in violence before the passage of the centre, and decreased after its passage; but the singular thing is that the noise of the thunder was hardly perceptible, perhaps because of the roar of the wind and the cracks of falling buildings. Ball or globe lightning was frequently seen, especially in the country. The balls of fire traversed the air sometimes for several minutes at a time, and exploded when about one-and-a-half feet above the ground. Globes lightning has been observed to accompany tornadoes as well as volcanic eruptions, but we do not remember to have before heard of its appearance during a West Indian hurricane.

At the Blue Hill Observatory, United States, Mr. H. H. Clayton has been making a large number of measurements on the altitude of various kinds of clouds. He finds that the average height of nimbus clouds is 412 metres, of cumulus, at the base, 1,558 metres, of cirrus-stratus, 9,652 metres, and of cirrus,

the highest of all, 10,135 metres. The average velocity of cirrus clouds observed is 82 miles an hour, and their greatest velocity 133 miles an hour.—*Globe*.

TEMPERANCE DRINKS.

The following recipes for the manufacture of refreshing drinks for labourers working in the hay or harvest fields have been issued by the secretary of the Agricultural Department of the Church of England Temperance Society at Norwich. They are recommended as being less heavy and heating, more permanently sustaining and capable of quenching thirst than beer or any other form of alcoholic drink. They are also very pleasant to the taste and cost very little to prepare:—

(1) *Stokos*, which is prepared thus:—Put from 4oz. to 6oz. of fresh oatmeal, ground as fine as flour, into a pan; mix with a little cold water to the substance of cream, then add about 5oz. or 6oz. of leaf sugar, and half a fresh lemon cut in thin slices, with the pips taken out; then add a gallon of boiling water. Stir thoroughly while the water is being poured on. Use hot, warm, or cold. The lemon may be omitted, or any other flavouring used instead. Costs 3d. a gallon.

(2) *Cokos* is a good nourishing drink, made as follows:—4oz. of good fresh fine-ground oatmeal, 4oz. of cocos, add a little cold water, and mix into a thin batter, then add 4oz. of leaf sugar and a gallon of boiling water; take to the full in a stone jar. Costs 1½d. a quart.

(3) *Bopkos* is a good harvest drink. Boil ½oz. of hops and ½oz. of ginger (bruise) in ½ gallons of water for 25 minutes, add 1lb of best brown sugar, and boil 10 minutes more, then strain and bottle, or put into a cask while hot; it will be ready for drinking when cold. Keep in a cold place. Dried horse-dung may be used instead of hops. Costs 3d. a gallon.

KENTISH HOPS AND INDIAN TEA.

[We had heard a good deal recently about hop tea, but we had no idea it had assumed the importance attributed to it in the following account.—*Ed. T. A.*]

A fair maid of Kent—somewhat idealised, if one may judge from the lady hoppers one passes on the Maidstone Road—exchanging cordial greetings with a dusky damsel from Hindustan, effectively symbolises the industry which was called into existence some year or more ago by the inventive genius of Mr. H. A. Snelling. It is a bright and taking poster. We had seen it on the London boardings, and in Maidstone again it meets the eye at every turn. There is something captivating about this sentiment of bringing the two ends of the Empire together to contribute to the contents of that dearly-cherished institution the English teapot, but—

“Apart from the picturesqueness of the idea, how on earth,” I asked Mr. Snelling as we walked down the High Street of Maidstone together, “how on earth did you come to think of Hop Tea?”

“Well,” said Mr. Snelling, “I had the idea vaguely in my mind for some time. Then one day I got a fine sample of dried hops and made an infusion with them: the result was something like a cup of extremely pungent Indian tea; after which the idea took definite form. I mixed the hops with tea in certain proportions, and eventually, having satisfied myself that I had got a good thing, I took out my patent, and you know the rest. Of course,” continued Mr. Snelling, “this is not a mere question of taste, although, as a tea taster of experience, I hold that the judicious admixture of hops makes a marked improvement in the flavour of tea—which is generally admitted now; but the invention has a very practical aim from a hygienic point of view in which connection we attach great importance

to the opinion of Dr. Adams as to the therapeutic value of hop tea, and I should like to quote it if you write anything about our business.”

The following, therefore, in obedience to this request, is what the President of the Public Society of Analysts of the United Kingdom has to say on the subject:—“This is to certify,” he writes, “that the sample of hop tea submitted to me for analysis consists of blend of pure Indian and Ceylon teas with Kentish hops, and contains no admixture whatever. These constituents are manipulated and dried in a most skilful manner, so as to develop the volatile oil which imparts the grateful aroma that is the special characteristic of the best teas. The chemical analysis discovers in unusual abundance the alkaloid theine—the substance to which tea owes its valuable properties as a food—giving rest and comfort to the weary, tranquility in nervous excitement, and, by some marvellous means, while preventing waste of nervous energy, promoting intellectual activity. As it appears to me, this combination of tea and hop is a most happy idea, by which the undesirable property of ordinary tea—namely, its astringency—is sensibly diminished and modified, whilst at the same advantageous tonic property of the hop introduced. In my opinion the hop tea will prove to be a great boon to many persons hitherto debarred owing to excess of astringency, the use of ordinary tea.”

There is no questioning the value of such testimony, although to the common-sense consumer it hardly needs the opinion of a scientific expert to demonstrate the advantage of counteracting the evil effect of excessive tea-drinking upon the nerves and digestion by the addition of an ingredient which is admittedly a valuable sedative and an excellent stomach tonic. Conceivably, there may be thousands to whom tea has been a forbidden luxury who may henceforth, through this simple invention, find no bar to their enjoyment of it; and this, indeed, seems to be the case, for in the comparatively short time in which hop tea has been before the public the demand for it has grown throughout the country to an extent which sufficiently illustrates the hold which it has taken upon the public fancy. Upwards of fifty or hundred local agents sell it throughout the United Kingdom, and one retail agent alone is credited with the sale of 15 tons in six months.

The idea of mixing hop coxes with tea seems sufficiently simple, but the manipulation is hardly simple enough—even were it not protected by patents—to permit of the trade being taken up by any whose close study of the subject does not justify their posing as experts. It was very early discovered, for instance, that brewers' hops, dried and prepared in the usual manner and exposed to sulphurous fumes, were totally unsuitable for tea-blending, where delicacy of flavour must be retained. Hence the Hop Tea Company, to whom Mr. Snelling disposed of his English patents, found themselves under the necessity of treating the hops *ab initio*, and hence the pleasant tea-house on the Medway of which I had heard so much, and to visit which was one of the objects of my day at Maidstone.

This picturesquely-situated factory condenses its year's work into about eight weeks—the Kentish hop season—in the course of which time sufficient hop must be prepared to cover the estimated requirements for the ensuing twelve months. The hops come in fresh from the surrounding country: the factory is now at its busiest, and the hops were arriving when I was there—fresh, green, and fragrant—with that seductive and indescribable hop-fragrance which, like the flavour of tomatoes, grows upon one by familiarity. On arriving, the hops are spread to “withor” for six or eight hours on trays in the upper floor of the factory, across which a thorough draught of fresh air blows from the Medway and the open country beyond. After the “withering,” the hops go to the rolling machine, wherein about a ton a day are triturated between two wooden surfaces. The crushed hops are then sifted, and the thicker stalks that will not pass the sieves are put back for another crushing; then, after being

allowed to ferment for two to four hours, they pass into a "Siropoco" tea-drying machine, and, after exposure to hot air at 300 degrees for about 20 minutes, they are ready for packing for despatch to the London warehouse.

The essence of Mr. Snelling's system lies, it will be seen, in the adoption of the regular tea-growers' methods, and in perfecting it he enjoyed the advantage at the outset of the practical co-operation of one of the best known of the Assam planters, Mr. Patrick Eugene Macgregor, who undertook the manipulation of the first samples of hops that were treated at Maidstone last year. The ordinary system of hop drying for brewers purposes takes about ten hours, during which the hops are exposed to the fumes of sulphur and charcoal. In the "Siropoco" the process is rapid and effectual, and the hops come in contact with nothing but heated air.

Here, then, ends the Maidstone part of the history of the hop tea manufacture. The blending takes place in the London warehouses and here it may be well to note that none but carefully selected India and Ceylon teas are used. The hop, notwithstanding its crushing and sifting, requires some further cutting in a machine to ensure its perfectly mixing with the finer leaf of the tea shrub, but in the mixing process there is nothing distinctive apart from what may be seen in any tea warehouse.

Hop coffee and hop cocoa are other preparations which are covered by Mr. Snelling's patents, and the production of which forms a part, although a minor one, of the Company's operations. In these cases, to ensure a perfect mixture, the hops are ground to an impalpable powder. The Hop cocoa, in particular, is a very pleasant preparation, the bitter of the hops counteracting to a great extent the native greasiness of the cocoa flavour which is objectionable to many people.

Kentish people are proverbially loyal to their native industries. Above everything they believe in hops, and the hearty way in which hop tea has been taken up locally is very edifying. All the tea dealers sell it; you may get it, I believe, at all the hotels—or at least, in my experience, at the leading one ye ancient Bell.

For the original and existing Hop Tea, Company confines its field of operations to Great Britain alone, but Mr. Snelling has secured his patent rights wherever they can be secured all over the world, and the Hops Tea Foreign and Colonial Syndicate (Limited) has recently been registered, with the object of doing, either by sale or licence, with the patents granted for Belgium, Denmark, France, India, New South Wales, New Zealand, South Australia, Tasmania, Victoria, the United States, Canada, Queensland, Norway, Sweden, and Russia. The shares in the syndicate are being privately subscribed, but some proportion will be offered to the public, and agents and consignees everywhere are in demand.—*European Mail*

VISIT OF AN AMERICAN PROFESSOR TO CEYLON.

The American Professor Goodale who visited the Ceylon botanical gardens some time ago, calling, when in Colombo, at the *Observer* Office, communicates the result of his visit to the *American Journal of Science*. But for a regrettable oversight the details would have appeared in our columns some time ago.

1. Botanic Gardens in the Equatorial Belt and in the South Seas (First Paper).—It is my purpose to give, in the following notes, some account of the more important Botanic Gardens visited by me during a recent journey. The tour carried me from Genoa, through the canal at Suez, to Ceylon, in which country Peradenia and Hakgala were examined; thence to Adelaide in South Australia; Melbourne and Geelong in Victoria; Hobart in Tasmania; Dunedin, Christchurch, and Wellington, in New Zealand; Sydney in New South Wales; Brisbane in Queensland; Buitenzorg in Java; Singapore in the Straits Settle-

ment; Saigon, Hong Kong, and Shanghai, in China; and Tokio in Japan. With the exception of Shanghai and Tokio, the visits were made at favorable seasons: in northern China and in Japan the spring was not far advanced, but the early flowers were in perfection.

The journey was undertaken with a view of securing from the establishments in question for the University Museum at Cambridge, specimens illustrative of the useful products of the vegetable kingdom. In every instance, the writer met with a cordial reception and received innumerable courtesies for which he desires to thank again the directors, curators, and superintendents of the various botanical establishments. Every facility was afforded for careful inspection of the workings of the gardens and museums, and, it should be added, of the educational institutions with which some of them were connected.

A satisfactory photographic outfit rendered it possible to supplement the collection of photographic views which were purchasable at most points; so that the series, now stored in the Museum at Cambridge, may be regarded as one of the largest yet brought together. It comprises views not only of groups of plants both in gardens and in their wild state, but of individual plants as well. Early next year these illustrations will be accessible to visiting naturalists.

The present sketch will follow essentially the route outlined in a preceding paragraph, beginning with the gardens in Ceylon.

PERADENIYA AND HAKGALA (CEYLON).—After the desert of Egypt and Arabia, and of treeless Aden have been passed, the traveler comes, by an abrupt transition, upon tropical luxuriance of vegetation. There is to be sure, a distant glimpse of Socotra, but its shores are too far away to yield anything plainly discernible, and even Malicoy, an island lying between the Maldives and Laccadives, gives only a faint suggestion of plant life. Its low-lying land is fringed with scattered coconut palms, of which, later, one sees so many. Before reaching Ceylon the ship passes within sight of the southern point of India but not near enough to show what its plants are like. In fact, therefore, the arrival in the harbor of Co'ombo brings a surprise. Coming down to the shore, and extending as far as the eye can reach on either side, are crooked* coconut palms, here and there intermingled with trees having foliage of the deepest green. A botanist is struck at once by the superb capabilities of such a country for a tropical garden. These capabilities were not overlooked by the Dutch, who succeeded the Portuguese in possession. A Botanic Garden was founded by them at Slave Island in Colombo, but when the Dutch were driven out by the British it fell into neglect. There was, however, at this period, an excellent garden connected with the country place of the first English Governor, near Co'ombo, which at the beginning of his century was under the charge of a naturalist, who gave it somewhat the character of a botanical garden.

In 1810, Sir Joseph Banks sketched the plan for a Botanic Garden in Slave Island, Colombo, and succeeded in transferring thither from Canton, Mr. Kerr, who became its chief. According to the work from which I have derived these facts, the Slave Island garden was found subject to floods, and consequently the establishment was moved to Kalutara. One finds here and there in Co'ombo trees of the old occupancy remaining in the names of some of the streets,—“Kew” for instance. From Kalutara the garden was transferred in 1821 to its present site. Since that time, the large garden has established four branches, in order to secure all the advantages which can come from having land at different altitudes and with different exposures.

The branch gardens are (1) Badulla, founded in 1886, in the eastern part of the island, with an elevation

* Crooked conveys the idea of sharp angles, whereas the coconut palms are gracefully bent.—ED. T. A.

somewhat over 2,000 feet. "The climate here is somewhat drier than on the western side of the hill region, receiving but little rain with the southwest monsoon." (2) Anuradhapura, dating from 1883, about a hundred miles north of the large garden, is the ancient capital of the island. Besides the interesting ruins at this point which are well worth seeing, there exists the oldest historical tree in the world, *Ficus religiosa*, (the sacred Bo), assigned to 288 B. C. This garden has a short rainy season and a hot dry climate. (3) Memaratgoda, 33 feet above the sea, and thoroughly tropical, is on the railroad running from Colombo to Kandy. It was founded in 1876. Here certain plants which cannot be grown at Peradeniya are very successfully cultivated. (4) Hakgala, established in 1860, as a nursery for Cinchona cultivation, is near Nuwara Eliya, (commonly pronounced "Newralia") the famous sanitarium. It is almost 6,000 feet above sea-level,* in a place of surpassing beauty. Above the garden is a frowning double cliff 1,500 feet, high, and all round, the views are most attractive. The Gate affords one of the best of these. The landscape reaches over the Uva district towards the Haputale gap and the Madulima hills. On entering the garden the bewilderment begins. On every hand one sees species in the most grotesque juxtaposition. Plants from Australia such as Casuarinas and Acacias are perfectly at home with East and West Indian, Japanese, and English plants. Of the latter there are many which seemed thrifty and well established.

Although the garden is used primarily for experimental purposes it has been laid out with regard to effectiveness of grouping and with remarkable success. A botanical visitor is, however, constantly trying to separate in his mind the different plants from the curious collocations which everywhere abound and demonstrate better than in any other place I have ever seen, the wide range of tolerance of climate. The Superintendent Mr. W. Nock, who has had large experience in the West Indies, has carried on some interesting experiments in acclimatizing plants from the western hemisphere, such as "cherimoyer" and the like. There are few plants in the garden more attractive from an economic point of view than the vegetables of doubtful promise, such as Arracacha, and those of assured culinary position "Ochoe" or "Ohoche" (*Secchium edule*) for example. Some of the medicinal plants in hand were doing well in every way, while others have proved somewhat disappointing, for instance, jalap and ipecacuanha.

The ferns, especially the tree ferns, and the species of *Eucalyptus* form one of the marked successes at this garden. Mr. Nock stated that the most troublesome weed in the garden is a species, (perhaps more than a single species) of *Oxalis*: it is simply impossible to eradicate it.

Peradeniya.—The gardens are four miles from Kandy, and about eighty from Colombo. The railroad passes through lowlands and rice-fields, past native villages surrounded by plantains and coconuts, and through occasional jungles, until it reaches higher ground. The scenery changes rapidly, forests now and then appearing in the foreground, with occasional views of distant castellated mountains. As the mountains rise out of the terraced rice-fields and from the shrubs of the jungles, the eye catches on every hand glimpses of groups of bent coconut palms and straight arecas. It is difficult to realize that those palms mean, perhaps without exception, human habitations at their feet. Through these scenes of enchanting beauty, the railroad has made its way, demanding here and there very skilful engineering. The track is lined with *Lantana*, which is slowly giving way before the encroachments of a still stronger invader, a Composite from Mexico,† *Mimosa pudica* is also widely spread as a strong weed.

The drive from Kandy to the great garden is through a well shaded street lined with native houses. There are gathered at short intervals into villages.

* Somewhat over 5,000, would be more correct.—Ed. T. A.

† The "Californian daisy," really a perennial sunflower, is referred to.—Ed. T. A.

My first visits to this garden were made, as were those in every other instance save one on the whole tour, without reporting to the Director. In this way a student can take things very leisurely, and look up matters of detail which it is not right or courteous to trouble the chiefs with: later, all special points of interest which have escaped notice are likely to be brought out by a walk with the Director. The establishment at Peradeniya consists (1), of 150 acres of garden proper and arboretum, (2) of a museum and herbarium with library attached. The Director, Dr. Henry Trimeu, widely known as an author and editor, controls not only these, but the branch gardens as well, making his headquarters at Peradeniya.

Once for all it may be said that botanists are made welcome in every way, finding every facility for carrying on systematic work. The climate is healthful, provided one takes ordinary and reasonable precautions against exposure to the direct rays of the sun in the hottest part of the day. If I remember rightly the director, even in his long walks through the garden and in his excursions seldom wears the conventional pith-helmet. American students need not fear that they will suffer greater discomfort from the hot weather at Kandy and Peradeniya than in summer in the United States and Canada. Access to Ceylon (and for that matter, Java) has now been made so easy by the newer swift steamers, that it seems advisable to mention these facts about the climate.

It is impossible to describe the wealth of material placed at the service of every visitor to the two great gardens of the equatorial belt, that under present review and the one at Buitenzorg to be considered in a subsequent note. It is equally impossible to institute a comparison between the two.

In both of these vast establishments, the student finds magnificent specimens of all or very nearly all the useful plants belonging to hot moist climates. Many years ago the writer had the privilege of seeing tropical plants at the Isthmus of Panama, but even the delightful impressions received on that occasion, which had perhaps become deepened with the lapse of time, were forgotten in the presence of the abounding luxuriance of these palms, bamboos, glossy-leaved evergreens and tangled climbers.

At Peradeniya the most characteristic plants are so placed as to be seen to good advantage. This was frequently observed when in search of points of view for photographing individual specimens. Moreover, the system of labelling is about perfect, Dr. Trimeu makes use of a large stiff formed out of baked clay, shaped so as to give an inclined surface on which the name is plainly painted. The brick red labels with their painted disk are not unattractive; at any rate, they do not detract from the general effect of the broad lawns bordered by gigantic trees.

The most remarkable single tree in the garden is the Seychelles Palm or double coconut, now almost fifty years old. The giant and other bamboos, the grove of India-rubber trees near the main entrance, and the avenue of *Oreodoxa*, are only a few examples of the finer groups of single species. The most imposing group of different species is that of the palms not far from the gate. The classified arboretum is rich in fine specimens, the principal orders being represented on a generous scale.

The nurseries, kitchen-garden, rockery for succulents, forneries, and clusters of economic plants are on a scale commensurate with the arboretum. As might be expected, the orchids are by no means so fine as the collections one sees in large private establishments in England and on the continent: it is not possible to command the conditions of growth for all the finer species with the same degree of certainty as in colder regions where a stove means something.

At the time of my visit, *Antherisia nobilis* and the great crane myrtle were in full flower, and a large Talipot palm in bloom was one of the most conspicuous objects. I was a little too early in Ceylon for some of the tropical fruits, and too late for a few others, but fortunately was able to remedy this lack farther on in Queensland and Java.

Among the finest of the photographic views of the gardens in Peradeniya are the following:—(1) the

main entrance, with the long lines of Assam rubber trees, and the cluster of different palms, (2) the avenue of royal palms, (3) the different bamboos at the ponds, (4) the distant view of the sawwood bridge. The view from the Herbarium is also one of great beauty.

Visitors to the gardens are greatly assisted by the intelligent native servants detailed to act as guides. They have a fair knowledge of the whereabouts of almost all the important plants and seldom go wrong with regard to names. It should be stated also that the natives employed in widely different stations in the establishment prove, according to the Director and the Superintendent, general efficiency.

The Herbarium is rich in certain directions and can be consulted by students under proper restrictions. The Museum is as yet small.

It remains to be said that plants and seeds are for sale at the garden, at moderate prices. A Wardian case packed with forty assorted plants is shipped for 40 rupees, say about 16 to 20 dollars.

The influence for good which has been exerted in Ceylon by the garden and its branches is incalculable. The establishment has proved a centre of scientific activity and of high economic value.

G. L. G.

G. A. SALA ON TEA DRINKING.

A feminine contributor to a contemporary appears, equally with the estimable Mrs. Fawcett, to be desperately troubled in her mind touching the supposed enormities of tea-drinking by ladies—excesses which in the opinion of the enemies of the tea-pot, are grievously aggravated when the cup which cheers but not inebriates is accompanied by huns, scoops, shortbread, and especially by the dark and dyspeptic plumcake. The foes of tea maintain that there is an utter lack of dignity in the spectacle of a bevy of ladies sitting at marble tables munching indigestion-breeding plumcake and sipping equally unwholesome tea “from thick white bowls conventionally known as tea-cups.” It may be asked, however, is it absolutely essential to tea-drinking that the refreshment should be taken from a marble-topped table? Would it be equally criminal to sip Southerg or Bohoo while sitting at a table of plain deal covered with American cloth, or at an “occasional” walnut, or mahogany, or rosewood, or from the convenient and pretty dwarf table of ebony and mother-of-pearl—the “mikra trapeza” which the Greek ladies use as a support for the brass plateau that holds their dainty little coffee-cups? And, again, leaving on one side as a moot point the wholesomeness or unwholesomeness of tea, is it not foolishly ostentatious, in the year 1891, to call our teacups “thick white bowls?” At least, they have handles, and are supplemented by saucers; and, if the correspondent of our contemporary entered a Parisian crémère in quest of a cheap breakfast, her café au lait or her chocolate would be served in what was literally a thick white bowl, very often with the white glaze chipped off in portions, and revealing the coarse brown earthenware beneath, and utterly destitute of a handle, to atone for the absence of which the customer would be furnished with a big spoon of the very cheapest and most lack-lustre form of electro. Even in the most fashionable cafés in Paris, the tea and coffee cups are thick and white and clumsy in potting, whereas in hundreds of houses of refreshment in London and at the seaside the tea equipage is light, pretty and tasteful. English pottery is fast becoming not only the most elegant but the cheapest in the world; and, seeing that quite a picturesque little tea service can be bought for five or six shillings, the stingiest of refreshment-house keepers would scarcely think it worth while to serve coffee in thick white bowls.

Nor does the indictment against tea stop at the charge that it is served at marble tables and with ugly and clumsy paraphernalia. The ladies are warned that, although the decoctions of the fragrant herb at “tea-time” may be grateful and comforting, tea at

“luncheon-time” is a delusion and a snare. In response to this somewhat vague accusation it may be permissible to ask what is “tea-time?” We did not discover the properties of the tea-plant; the Chinese grew it and dried it and infused it thousands of years before England was ever heard of, and your Chinaman will sip tea from morning until night. Even in England, since the period when the use of tea was first introduced, the hours at which we take our meals have been so frequently varied that it is a matter of extreme difficulty to decide at what hour tea should most appropriately be consumed. Pope tells us that “Great Anna, whom three realms obey, Did sometimes counsel take and sometimes tea”; and, looking at the fact that since in the days of Queen Anne Royalty and the nobility and gentry breakfasted at eight in the morning, dined at one, and supped at eight, it is probable that tea-time may have been between three and four p.m. There was, however, as we learn from Swift’s “Polite Conversation,” a section of the beau monde which did not breakfast until nearly noon. Miss Notable, when Tom Neverout comes to breakfast at Lady Smart’s, admits that she never rises before eleven, and it is at that hour that her Ladyship entertains her guest with tea, which is served with cream, and bread-and-butter. The tea, of course, is in a “dish” which may have been a small china bowl without handles. Hogarth’s early pictures are replete with evidence that the little black boy in the turban who bore the teakettle was in request not only at the orthodox tea-time, but at various periods throughout the day. Lady Smart, being apparently rather a dissipated dandy, does not dine until three; but when she has regaled her guests upon oysters, sirloin of beef, venison, pastry, pigeons, pudding, cider, and small beer, the ladies adjourn to their tea, while the gentlemen sit down to serious drinking of claret and burgundy. When they are pretty full of choice Gallic vintages they rejoin the ladies, and tea is again served round to both sexes. Next Lady Smart rings for the footmen, and bids him take away from the tea-tables and bring candles, it being understood from the context that it is now six o’clock on a September evening. Then they all go to quadrille, manille, spadille, and basto, and gamble furiously until three in the morning, more tea, and possibly a little punch having been served in the small hours. To all appearance, although the use of tea throughout the eighteenth century was from its great coolness almost exclusively confined to the upper classes, it was drunk quite as frequently in polite society as it is a present by all orders in the community; and it is worthy of remark that from the time of its first introduction into Europe it has been subjected to most violent attacks, now on the part of the medical profession, and now on that of these professors of minor morals who are always so anxious to put their fellow-creatures on the right path, but whose ignorance, prejudice, and lack of common sense lead them with melancholy frequency to follow a very wrong path themselves. There is no notice of tea being habitually drunk in England prior to the Restoration; but as early as 1611 Tulpius, a celebrated physician of Amsterdam, advised all his female patients to drink tea when they suffered from depression, and it is extremely probable that when Mary ascended the throne of these kingdoms as consort regnant with her husband, at the Revolution, she brought with her from Holland a canister of tea, as well as a provision of Dutch tiles, Dutch clocks, charity schools on the Dutch model, Dutch drops, Dutch dolls, and Dutch cleanliness. Tea made but slow progress in France until after 1789, but in 1801 we find the author of the “Almaoach des Gourmands” complaining that tea-parties, taking place at the unholy hour of three in the morning, had supplanted the “goûters,” or after-suppers, of Parisian society. These post-tea teas were attended by dishes of game and pastry, and by libations of punch and bishop; but, at about the same period, it would appear that the frugal and patriarchal Swiss had established a regular five o’clock tea, to which, in its original simplicity, only bread-and-butter was added, although subsequently such complementary delicacies as biscuits, macarons, and even ices were tolerated.

At the present day the manner of the world's tea-drinking may be rapidly surveyed and briefly summarised. The Chinese and Japanese enjoy the decoction of the herb just as their forefathers have done for unnumbered generations. The Anglo-Indians have their very early cup of tea with a thin slice of bread-and-butter, the snack being known as the "chotahazri," at five or six in the morning, a good two or three hours before breakfast, at which last-named meal tea may vie with coffee as a beverage; and again, in Anglo-Indian society, the kettle-drum, or five o'clock tea, takes a conspicuous place. European Russians of the civilised classes drink immoderate quantities of tea in tumblers, without milk or sugar, but with the zest of a slice of lemon-peel, at all hours of the day. Among the peasantry and the artisans the coarser kind of black tea is extensively patronised. South of Moscow "brick tea"—that is to say, the inferior leaves of the plant mixed with sheep's blood, and pressed into the form of cubes—is the ordinary drink of the common people, and holds its own with vodka and vas. The Tartars swill a horrible gruel, thick and slab, of "brick tea," sweet, salt, pepper, and sugar, boiled in a chaldron. The Turks and Greeks, nationally speaking, know nothing of tea. Nor is it a very recognisable quantity in the dietary of the Latin races, the Spaniards preferring chocolate and the Italians black coffee. The Germans are moderately fond of tea, but they like coffee better, and beer best. In Paris the use of tea is generally confined to polite society, and scarcely enters into the economy of "la vie bourgeoise." It is among the Anglo-Saxon peoples that the consumption of tea is most systematic and most extensive. The Australians are essentially a tea-drinking people. There cannot, indeed, be the slightest doubt that the cause of temperance both in Australia and United States has been materially advanced by the prevalence of tea-drinking; and, if our kinsmen beyond the Atlantic or on the shores of the Pacific really suffer from dyspepsia, it is possible that their tendency to indigestion springs much less from their custom of tea-imbibing than from their habit of eating beefsteaks and mutton-bops for breakfast. As regards England, we wholly fail to see that the consumption of tea is immoderate, that it has injured the health of the community, or that it has diminished the native grace and dignity of Englishwomen. Envy, malice, and all uncharitableness are much more conducive to indigestion than five o'clock tea.—*Daily Telegraph*.

RICE, ITS HISTORY.

By MR. H. B. PROCTOR.

"Thus God created man, God made food and drink, Rice, fire, and water, cattle, elephants, and birds."—A Burmese account of the Creation.

Extraordinary as has been the progress of the wheat trade of England during the last century, the wheaten loaf having supplanted those of rye and barley as the staple food of all classes of the people, it nevertheless will not bear comparison when contrasted with the same movement in rice, the importation of which has increased not less than one hundred-fold during the same period.

The rice trade of England continued in extremely small compass, and was limited to the varieties produced in Carolina, Bengal, and Madras, until the year of 1852, when the most fertile provinces of Burma were conquered and annexed to the British empire.

Of all the countries in the world, Burma is the best adapted for the cheap cultivation of rice; all that was wanted was a just and strong government, able to put down petty internal warfare, and willing to protect the cultivators from excessive taxation, violence and oppression.

These blessings, which universally attend British rule, soon changed the condition of the people from extreme poverty to the greatest prosperity. As soon

as the war was over, and the country became settled the export trade in rice began, and since then it has steadily increased year by year, until in 1881 the exports to Europe amounted to no less than 736,650 tons, besides which 178,600 tons were exported coastwise and to other parts of the world.

This immense addition to the rice supply of the world has not checked the trade in the same article from the rest of India, as might have been anticipated, but it has grown larger too; last year, the exports to Europe amounted to 89,650 tons.

A cereal trade that is developing with such rapid strides cannot fail to be of interest to the milling world. As the subject has hitherto been somewhat overlooked and neglected by periodicals devoted to such subjects, we propose to give a short account of the history, cultivation, and manufacture of rice and its products, together with a few remarks upon its comparative food value.

The derivation of the word—*arisi*, Tamil; *aruz*, Arabic; *oryza*, Latin; *riso*, Italian; *rice*, English, points correctly to its Indian origin. It is a cultivated variety of an aquatic grass, bearing when in the ear a closer resemblance to barley than to any other of the English corn plants.

The seed vessel grows upon separate, fine, hair-like stalks like the oat, each of which springs gracefully upwards from the main stem. The grain is inclosed in a rough yellow husk, which generally terminates with a thin spike or awn, though some varieties are awnless. The height varies from two feet to six feet, according to the variety. The grain must be removed from the husk, which adheres to it with great tenacity, either by being pounded in a stamper pot or more generally by passing it through a pair of mill-stones, set a slight distance apart, which crack off the husk without crushing the grain. It has next a thin skin or pellicle, which must be removed by scouring or decorticating, to make clean rice, just as barley is scoured for making pearl-barley. Rice in the husk is called "Paddy" (Malay, *Padi*); the husk which is removed is called Rice Shud; the meal which is obtained during the process is called Rice Meal.

There are far more cultivated varieties of rice differing more from each other than there are of wheat, or any other of the grain foods. The Karons, a hill race in British Burma, have names for forty varieties. Dr. Moore mentions 161 varieties growing in Ceylon, besides which there are those grown in China, Africa, Japan, and other parts of the world. The colors of the grain vary from coal black, dark red, pink, yellow, to ivory white; the shapes are various, and differ much from each other; some varieties are sweet, some others bitter; some oily, others dry; some hard and translucent, others soft and chalky. Botanists have classified the varieties into four divisions: Early rice, Common rice, Clammy rice, and Mountain rice.

Early rice is a marsh plant. It is sown between the end of March and beginning of May. It matures in four months. It is grown mostly in India, China and Japan. Carolina and Java rice belong to this division. The isolated attempts which have been made to grow Carolina rice in Burma have failed, because it ripens sooner than the main crop of the country, and the birds collect in such numbers as to clear off the bulk of the crop before it can be gathered in.

Common rice gives the greatest yield. About twenty-five-fold. It is wholly a marsh plant. If the ground becomes dry before it arrives at maturity it soon withers away. The Burmese crop belongs to this division. It is sown in June and reaped about six months after.

Mountain rice grows on the Himalayas. It does not require irrigation and will stand great cold, pushing its way through snow. It has been grown as an experiment in England.

Clammy rice has the advantage of growing on wet or dry lands. It ripens in five months. Varieties of the two first divisions are those most known in commerce.

There can be no doubt that the rice plant is of Indian origin. Wild rice, growing in the waste marshes, is still eaten as a luxury on the Madras coast. The grain is small, white, and sweet; it brings a high price, but the plant does not pay to grow, because it

returns so small a yield compared with the cultivated varieties. Rice is the grain food most preferred by half the human race. In the Indian peninsula it is the principal food of 100,000,000 of the people; so strongly are they impressed with the superiority of rice as a food that in Southern India a peasant will indicate his well-to-do or impoverished condition by telling you that he eats rice twice a day, or once only, or not at all. But the poorest people rarely taste it; they eat varieties of millet, raggy deri, or other cheaper foods.

Tradition teaches that rice is the most ancient food of India, and as such it is invested with almost a sacred character. It is used in many of the sacrifices and other religious ceremonies. One of the purifactory rites after birth is feeding the Hindoo infant with rice during six months. The Hindoo household must daily perform the five acts of worship, the fourth of which is scattering rice grains at his door, with the prayer: "*Om to all the Vishadevas, to the universal gods, men, beasts, birds, reptiles, etc.*" After death comes the most important rite of all, called "Araddha," which is offering the pinda or ball of rice, accompanied with prayers and libations to the departed spirit. The participation in this rice is accepted as evidence of kinship, and gives a title to a share of the deceased's property.

The most ancient written account of the cultivation and trade in rice, as far as I have been able to ascertain, may be found in the Shoo-King or Chinese classics, translated in Motharst's Ancient China, which describes the drainage and irrigation works constructed by the Emperor Yu, on the Yangtse river, about 2356 B. C., a few years before the date usually given to the Noachian deluge. It describes the mode of collecting revenue from the paddy lands, as follows:—"To the distance of 500 le (110 miles) from the Royal City was the land of feudal tenure; for the first 100 le (28 miles), the revenue consists of the entire plant of the grain; for the second 100 le, they had to pay the grain and half the straw; for the third 100 le, they had to bring the grain in the ear, while all these rendered feudal service; for the fourth 100 le, they paid the grain in the husk, and for the fifth 100 le, they brought the rice cleaned."

A most ingenious mode of collecting the revenue where the cost of carriage is so great, and the roads so bad, as they are in China to the present day.

Coming nearer home, rice may certainly take its place among the cereals cultivated in Ancient Egypt and Syria. Pliny, the naturalist, does not give it in his list of Egyptian plants, but Wilkinson considers there is abundant reason for supposing it was cultivated in the Delta. This is confirmed by illustrations taken from a tomb at Thebes, some 3000 B. C. Wilkinson supposes that it represents the pulverizing of certain substances in a mortar. If it be compared with the process of rice cleaning as carried on in China at the present day, there can be no doubt but that it represents the same process as it was practised in Ancient Egypt nearly 5000 years ago. It is done by pounding the rice in wooden or stone pots, with a pointed pestle or beater; the pot is kept full of grain, so that the skin is removed by the continued trituration and friction of one grain against another, without pulverizing or breaking them. Another process is worked by the foot, which is the method preferred in Burma, Japan, and parts of China. The operation is referred to in Proverbs xxvii, 22: "Though thou shouldst bray a fool in a mortar among wheat (grain?) with a pestle, yet will not his folly depart from him," or as the same idea is rendered in one of our own proverbs, "Folly is more than skin deep." There is no sense in the translation as given in the authorized version. The word translated "wheat" means literally "pounded grain," and undoubtedly, refers to the decorticating process, which, according to Pliny and Herodotus, was applied to rice and barley but not to wheat.

Pliny's description of the rice plant seems to show, though he knew the grain, he had never seen it actually growing, the description is so wide from the mark. In his treatise on the food plants of India he says: "But the most favorite food of all these is rice, from which they prepare pisan (pearled grain) similar to

that prepared from barley in other parts of the world. The leaves of rice are fleshy, very like those of the leek, but broader; the stem is a cubit (18 inches) high, the blossom purple, and root globular, like a pearl in shape" (B. 18, cap. 13). He goes on to say that "Hippocrates, one of the famous writers of medical science, has devoted a whole volume to the praises of 'pisan,' the mode of preparing which is universally known."

The cultivation of the plant in Europe was, according to Captain Baird Smith, introduced by the Moors into Spain in the eleventh century, and from thence into Italy a century later. Gibbon considers that it was cultivated in Spain before the Christian era, and that the rice was imported from Spain which was used for making the wedding cake in the simple confarreation ceremonies of the old Roman Republic. Be this as it may, it is certain that it was not cultivated to any large extent in Italy until quite modern times.

Rice cultivation has always been heavily taxed, and in some of the states absolutely prohibited, owing to the malaria rising from the swampy lands. Since Italy became a kingdom and legislation on the subject has become more uniform and less capricious, the cultivation of this, the most profitable crop to the farmer, has so extended in the rice meadows of Lombardy and other similarly situated low-lying lands that the Italian rice crop of 1880 amounted to no less than 500,000 tons, and it is annually increasing in amount. The cultivation of rice in Georgia and Carolina, which have produced the finest seeds in the world, only commenced about the year 1790.

In a pamphlet published in London, in 1701, on "The Importance of British Plantations in America," it is mentioned as a recent circumstance, that "a brigantine from the island of Madagascar happened to put into Charleston, having a little rice seed left, which the captain gave to a gentleman named Woodward. From part of this he had a very good crop, but he was ignorant for some years how to clean it. It was soon dispersed over the province, and by frequent experiments and observations they found out ways of producing and manufacturing it to so great perfection that it is thought to exceed any other in value." Mr. Dubois, the treasurer of the East India Company, sent a further supply of seed a few years afterward. By careful selection of the seed, and cultivation in trenches on a suitable soil, the Carolina seed has become so famous that it has been exported to Java, Italy, Madras, and other countries. The finest Indian varieties are grown from American seed.

Since the American war and the abolition of slavery, as the free negroes object to working in the swampy rice lands, associated as they are with fever and malaria, rice cultivation is becoming less each year, and the export trade of Carolina rice to Europe in spite of all attempts to bolster it up with protective duties, has practically ceased. The American millers are losers rather than gainers by the duty imposed for protecting the trade, which is now two and one-half cents per pound, or over 100 per cent. *ad valorem* on imported cleaned rice, thus causing the American consumer to pay double for his rice. As the crop raised is smaller every year, he has not only no rice to export, but must import the balance of his supply from the English, or other markets. Were the duty removed, the more expensive Carolina rice would again be largely exported to Europe, and be replaced by a still greater import of Burmese rice for the American home trade, to the benefit of cultivators, millers, shippers, and all concerned; a remarkable instance of injury done to a trade by the duties intended to protect it.

It is difficult to trace the time when rice was first imported into great Britain. Shakespeare mentions it as a great luxury. The clown in Winter's Tale says:—"Three pounds of sugar, five pounds of currants, rice; what will this sister of mine do with rice? But my father hath made her mistress of the feast, and she lays it on." The supply then came from Italy. It was superseded early in the eighteenth century by rice from our American colonies and India. We did not begin to mill rice for ourselves to any appreciable extent until the early part of the present century

McCulloch in his Commercial Dictionary, in 1832, tells us that "a few years ago England was principally supplied with clean rice direct from Carolina; latterly it has been much reduced. An improved mode of separating the husks, which throws out the grain clean and unbroken, has been lately practised in this country. As the grain preserves its sweetness and flavor better during a long voyage than when shelled, it is now principally imported rough from Bengal and the United States. No doubt the heavy duty (15s. per cwt.) on American cleaned rice has powerfully contributed to this result. "He says the consumption which was lately only 2,000 to 2,500 tons annually is rapidly increasing," partly owing to the late reduction of the duty on Indian rice from 5s. to 1s. per cwt. It has now, however, been very generally introduced among the middle and to a certain extent among the lower classes; there can be little doubt that its consumption will continue to increase according as the various qualities of this cheap and highly useful grain come to be known. It is likely therefore, that it will in the future form an article of importance in the trade with India.

The experiences of the last half century show how these anticipations have been more than fulfilled. The rice imports have during that period increased a hundred fold; the increase still continues, and there is fair reason to suppose that the commercial enterprise, industry and mechanical ingenuity of the English people will, for many years to come, in spite of continental opposition, enable them to still farther develop and retain the foremost position in the rice trade of the whole world.—*Louisiana Planter and Sugar Manufacturer.*

SUGAR IN INDIA.

It may be remembered that in May last year, Messrs. Travers and Co., Limited, wrote to the Secretary of State for India on the subject of sugar production in this country. Reference was made on the point raised to the various local governments, and the following is the letter from the Government of India to the Secretary of State, covering the correspondence, dated "Calcutta, 24th December, 1889," and is as follows:—

"The improvement of sugar production and manufacture in this country has been the subject of attention both of the authorities and of capitalists since the beginning of the century, and various attempts have been made to establish factories, none of which appear to have been attended with any permanent success unless supplemented by the sale of rum and liquors. Sugar refining alone has not proved sufficiently profitable to maintain a factory. If this had been the case, there appears to be no reason why the industry should not have been largely taken up by private capitalists.

"Some of the main difficulties against which the industry has to contend are believed to be these:—

"(a) The cultivation of sugarcane is limited by the supply not only of water for irrigation, but also of manure.

"(b) As cultivation in India is confined to small farms or holdings, each cultivator who is able to grow the crop at all can only find manure enough for a small area, generally less than half an acre, of sugarcane. The plots of sugarcane are therefore greatly scattered, even in a canal-irrigated tract.

"(c) A central factory has accordingly to bring in its supplies of cane in small quantities over varying distances, in many cases the distance being great.

"(d) The carriage of canes over long distance even in a climate like that of the Mauritius, is detrimental to the juice for purposes of sugar-making. It is much more so in India, where the canes ripen at the season when the atmosphere is driest and suffer, therefore, the maximum of injury.

"(e) The Mauritius system of growing large canes at intervals is not adapted to the greater part of India where, in order to prevent the ingress of dry-air into the fields, small canes have to be grown in close contact,

"(f) The amount of cane which can be grown, limited as it is by the supply of water and manure, barely suffices for the wants of the Indian population. It seems to be at present as profitable to produce coarse sugar for their use, as highly refined sugar for export. There is, therefore, no sufficient inducement to capital to embark on the more difficult and expensive system.

"A further obstacle to sugar refining in India exists in the high differential rate which the conditions of our excise system require to be placed upon spirits made on the European method, as compared with that levied on spirits manufactured by the indigenous process. The sugar refiner in India is thus placed at a disadvantage in respect to the utilisation of his molasses in the form of spirits.

"In view of the circumstances above noted, we are unable to advocate any attempt being made at the cost of the State to establish model factories. We are inclined to attach much confidence to the views and conclusions formed by Messrs. Thomson and Mynio, who have paid, for many years, practical attention to the subject of sugar cultivation and manufacture by ryots, and were the first to introduce the portable sugar-mills which have now spread over India. They advocate the gradual improvement of the ryots' method of manufacture rather than the introduction of more expensive and centralising systems. The Provincial Departments of Agriculture have, of recent years, directed attention to this question, and may usefully be desired to continue to do so.

"We are also willing to advocate the establishment of agricultural experiments in those comparatively limited tracts of the country (such as Eastern Bengal, where there is a moist climate and a more or less abundant supply of manure) in which the Mauritius methods of cultivation have *prima facie* prospects of success, and we are prepared to advise our local governments and administrations to give every reasonable support to sugar factories and refineries which may be established by private enterprise."

Messrs. Travers's reply to the correspondence is dated 21st February, 1890:—

"We observe that while all the officials who have reported fully confirm our information as to the great, and indeed excessive, waste in Indian sugar manufacture, yet that they are able in some degree to explain the causes of the existing state of things, while the opinion is general that it would not be wise for the Government to establish experimental central sugar factories.

"It would be presumptuous on our part to offer any comments on a question so fully taken up by the local authorities on the initiative of the Secretary of State.

"It only remains for us, in concluding the correspondence, to acknowledge the very great courtesy with which our necessarily imperfectly informed remarks have been received, and the promptitude with which action has been taken owing to the recognition by the India Office and the local authorities of the great importance of sugar manufacture to India, and the possibility of a great development in it.—We are, &c.,

"*M. J. Travers and Son, Limited,*

"(Signed) J. W. ROGERS.

"P.S.—We may mention that 'German' granulated, a small white dry crystal sugar made direct from the beetroot, is now being shipped from Hamburg to India; so that the ryots will not have Mauritius only to compete with at home. We believe this sugar costs about 16s. per cwt. laid down in Bombay, and that the bounty on its export does not exceed 6d. to 9d. per cwt.—*Pioneer.*

RICE CLEANING IN HONG KONG.

The United States Consul at Hong Kong says that all the rice received there is unclean, with the exception of that brought from China, the average of paddy being about 20 per cent. It is prepared for market at Hong Kong, with the exception of those shipped to Canton, which, owing to the cheapness of labour in comparison with Hong Kong, is cleaned

there. The process of cleaning is slow, and the labour most harassing. It is first run through hand sieves to separate the paddy from the grain. The paddy is first run through a machine made of wood, shaped not unlike a set of millstones, both sawn from a log about three feet in diameter. Into the face of the under block, and flush with it, is let a circular stone of a diameter to leave a five-inch rim of wood. This stone is opposed to an opening or eye in the upper block of a like diameter, into which is fitted a perforated board. The opposing surfaces of the two blocks are cut into grooves three-eighths of an inch wide, one-fourth of an inch in depth, and about the same distance apart, the intervening ridges of wood being carefully trimmed about every three hours, in order to be kept sufficiently sharp. The upper block is dragged round by means of a hook at the end of a wooden handle fastened to a staple driven into the rim, a single workman turning it and, at the same, feeding the machine by throwing the paddy with a wooden paddle into the eye, from which it is distributed outward by the centrifugal force. This breaks and loosens the husk from the kernel, after which it is run through a fanning mill, constructed with about the same regard to mechanics as the rudimentary machines described above. The grain, divested of husk, is now ready for the scouring process, which is done in stone mortars, holding about a bushel. These are set into stonework level with the floor, at an angle of about 30 degrees, twenty or more being distributed about, according to the size and shape of the room. A wooden framework is built over the mortars in such a way that a stone pestle, weighing twenty-five pounds, fixed to a beam pressing over a fulcrum, is rapidly dropped upon the grain. This is accomplished by a workman, who steps quickly upon the short end of the lever, and as quickly removes his weight when the pestle has been elevated to the highest point. The number of strokes considered necessary for this part of the process varies with the kind of rice, from two to four thousand. Ashes made from rice husks, to the amount of one-fourth of a pound, are added to each mortar of grain at the beginning of the pounding, and a second time when the pounding is half finished, the rice by this time having become quite warm. It is now taken from the mortar to be sifted, after which it is replaced for foot-scouring, ashes being added for the third time. A barefooted workman, supported from falling by reclining in a kind of swing, treads in the mortar, which causes a rapid movement of the rice. This is continued for from thirty to forty minutes, when it is taken out and sifted, and is now ready for market. A part of the dust, composed of ashes and disintegrated rice, resulting from the scouring, is combined with 10 per cent. of salt and used in preserving vegetables. What remains is given to swine. Consul Simon says that, crude as these appliances are, they accomplish the work with the least breaking and crushing of the grain possible, and no doubt comprise most of the principles upon which rice-cleaning machinery is, or should be, constructed. The rice merchants in Hong Kong say that owing to the cheapness of labour, improved machinery propelled by steam, such as is in use in Bangkok and Saigon, would not be profitable in Hong Kong, and would not be permitted in China, where a vast number of people find, in rice-cleaning, their only means of earning a living.—*Journal of the Society of Arts.*

BORNEO AS A FIELD FOR PLANTING ENTERPRISE.

Having travelled through the Island of Borneo, and observed in the course of my peregrinations what was being done in the way of planting, a short account may probably be of interest to planters.

Borneo lies in an easterly direction from Singapore, the distance being about one thousand miles. The climate throughout the year is almost the same, viz., the temperature remains almost unchangeable

(generally from seventy-five to eighty degrees in the shade), and heavy showers of rain, not infrequently accompanied by thunderstorms, fall every other four or five days, which give the atmosphere a most delightful freshness that never tends to make it either unhealthy or oppressive. Borneo is, comparatively speaking, a hilly country, and at an elevation generally from four hundred to two thousand feet. Planting is carried on principally in tobacco (coffee and tea on a small scale as yet), pepper, sago and tapioca and various kinds of fruits. A great number of Dutchmen have recently obtained valuable concessions from the British North Borneo Company for tobacco planting, and every year witnesses a great many people proceeding there—to say nothing of the large companies which are being continually formed to extend planting operations in that glorious Island. The Dutchmen, who are the principal planters, go in entirely for tobacco; and the first shipments which were sent home, about four or five years ago fetched the highest prices of any in the London markets. The result has been that more land is sought for, obtained and opened up, and the profits arising therefrom are immense, there being no native competition of any kind whatever to cope with. Coffee has also been a great success in the Government plantations, which lie about one hundred miles in a south-easterly direction from Sandakan, the capital of the British North Borneo Company, which is easily accessible by either steamer or boat. The natives have purchased quantities of plants which seem to grow remarkably well in their gardens. They do not grow any coffee for exportation, but simply enough for their wants; and this coffee, which they do plant, (Coffee Arabica) and which they do not appear to take pains about in cultivating, is certainly as fine as any I have ever tasted.

Tea is also grown, but not to any extent, for the simple reason, I presume, that no tea planter has as yet proceeded to Borneo (at least during my stay I never heard of one) for the purpose of trying whether it could be grown profitably or not. I do not profess to know much about tea, but the tea gardens I have seen in the Straits Settlements, which belonged to Ceylon planters, who told me they were as good, if not infinitely better than any in Ceylon, were certainly not richer or better looking than those I saw in Borneo. It seemed, as far as I observed, that it was a matter of perfect indifference whether tea or coffee was planted on the hills or plains as both appeared to thrive well on either the one or other without any trouble whatever. During my wanderings through the country, it was nothing unusual to come upon small tea gardens belonging to natives, all of which seemed to be growing up with the greatest luxuriance and profusion. The natives appeared to take not the slightest trouble about them, and it looked as if all they had to do was simply to plant and await results. Indigo has not, as far as I am aware, yet been attempted, but since my arrival in Calcutta, I have been asked by one or two planters regarding the soil, &c., &c., in Borneo, and from what I told them they were apparently under the impression that it would grow well there. I cannot conceive any reason why indigo, tea and coffee should not do well in Borneo, especially from what I have seen of the latter two, and I think it would be advantageous for those planters who have the time to spare to take a trip to that lovely country, and see what it is like for themselves. As I have already mentioned, Dutch planters are flocking in at present and are making piles of money in tobacco. They knew nothing about what Borneo was like, till they tried it with the above results; and why cannot indigo, tea and coffee planters do the same? The pepper vine, sago and tapioca are grown extensively, and flourish remarkably well, especially the former, on rich brown soils. Large concessions of land are easily obtained from the Company. The leases extend to nine hundred and ninety-nine years, and the amount to be paid to the Government is, I forget the exact amount at present, trifling.

Although the Dutch planters prefer Chinese coolies, whom they import, there are some twelve different tribes in Borneo, out of which any number of men

are to be had. I should imagine that Malays and Kadayans would be by far the best coolies to engage, as they chiefly devote their time to agricultural pursuits, especially those who dwell in the interior. Labour is also cheap, in fact in some parts of the Island money is totally unknown. A native would think far more of a few empty beer bottles or empty tobacco tins than he would of a handful of dollars. This, of course, applies to the inland tribes. As a rule, the natives are most peaceful and obliging, and I should not think that any difficulties in the shape of organising any amount of coolie labour which might be necessary would be met. The rainfall for the year in Borneo would, I think, compare favourably with that of India, although rainy and hot seasons, which make the climate of India so unbearable, are unknown. The sea breezes, which are wafted over the Island, are most refreshing, keeping the air always more or less cool, and such a thing as fever is almost unknown. The jungle in some parts is very dense, but it is astonishing with what rapidity the Malays fell it when they commence in earnest. There are a great many other things in Borneo as well as planting at which fortunes can be made, and a little capital is all that is necessary to accomplish this. But to go into detail would occupy too much space, and probably be of no interest. I have endeavoured, although I am afraid it is but a poor attempt, to show what prospects there are in the planting line; and if any of your readers desired further information regarding Borneo, I should only be too glad to give it. Communication is kept up between Singapore and Borneo and China by steamers and sailing vessels. I happened to be in Borneo when Lord and Lady Brassey paid it a visit in 1887 (Lady Brassey's last voyage in the *Sunbeam*), and I well remember how His Lordship spoke in such high terms of the country, and sunk a good round sum of money in a timber concern there. It only requires capital and good men, and if capital and good men were forthcoming, there is no saying what is in store for the latter, in that magnificent Island, which has been so truly described as "The Gardens of the East."—*Indian Planter's Gazette*.

OUTLINE OF THE HISTORY OF COMMERCIAL FERTILIZERS.

1. The history of fertilizers practically dates back to the time when bones were first applied to the soil and their value as a fertilizer was first recognised. Fertilizing with bones was first practised in England. Probably the first instance of their extensive application was in the case of the farmers living near Sheffield, England, who applied to the land the bone and ivory clippings, which were waste products of the knife and button factories of Sheffield. These clippings amounted to about eight hundred tons a year and were regarded, until about a century ago, as a nuisance, the disposal of which was a serious problem to the manufacturers.

In 1771 the agricultural use of bones was first publicly recommended by Hunter, and successful experiments were made with bone dust.

About 1814, Alexander von Humboldt called public attention to the use of guano as a fertilizer, which he had seen used by the natives of Peru.

About 1817, the first superphosphate is believed to have been made by Sir James Murray.

It was not until after 1820 that the use of phosphates assumed any great commercial or agricultural importance, and not even then was it appreciated what gave bones their value as fertilizers.

About 1830, Peruvian guano began to be imported into Europe as a fertilizer, and a few years after, into the United States, especially at the South.

About 1840, Liebig published the results of his researches and suggested that plants must obtain materials for their growth from the soil as well as from the air and water, which alone were previously supposed to furnish plant food; and, hence, that the proper life of a plant can be benefited by furnishing those elements that are necessary. It was shown that the phosphate of lime in bones gave them their

value, and that, by dissolving bones with sulphuric acid, they were made much more effective. The demand for bones then outran the supply. Other sources were looked for, and in 1843 a new source of phosphate of lime was found in Spain, consisting of a rock which contained considerable amounts of phosphoric acid. On trial, this rock was found to be a substitute for bone.

In the United States, farmers first used bones about 1790. The first bone mill was built about 1830, and super-phosphates were first used in 1851. The discovery of the so-called South Carolina rock was a great boon to those using commercial fertilizers, as this was found to take the place of bones.

The investigations based upon Liebig's theory showed that other elements in addition to phosphorus must be used to secure the best results, and, gradually, commercial fertilizers containing other elements came to be manufactured and offered for sale.

PRINCIPLES UNDERLYING THE USE OF FERTILIZERS.

2. Until fifty years ago, agriculture was without a scientific working basis. To the investigations of the illustrious German chemist, Justus von Liebig, we largely owe the advances that have been made in agricultural methods during the last half century. The following four laws, which form the foundation of modern agricultural practice, were fully established by Liebig:—

(1). "A soil can be termed fertile only when it contains all the materials requisite for the nutrition of plants in the required quantity and in the proper form."

(2). "With every crop a portion of those ingredients is removed. A part of this portion is again added from the inexhaustible store of the atmosphere; another part, however, is lost for ever if not replaced by man."

(3). "The fertility of the soil remains unchanged if all the ingredients of a crop are given back to the land. Such a restitution is effected by manure."

(4). "The manure produced in the course of husbandry is not sufficient to maintain permanently the fertility of a farm; it lacks the constituents which are annually exported in the shape of grain, hay, milk and live stock."

These four laws of Liebig contain a clear statement of the principles underlying the use of fertilizers; but, to understand their meaning with satisfactory clearness, we must know something more in detail about the following subjects:—

- (a.) The constituents and food materials of plants.
- (b.) The constituents of soils.
- (c.) The relations of soils and plants.

These subjects will now be considered in the above order:—

THE CONSTITUENTS AND FOOD MATERIALS OF PLANTS.

3. To chemical analysis we owe all that we know about what plants contain or are made of. Less than eighty years ago not a single vegetable substance had been accurately analyzed; and although in the thirty years following much was learned about the different elements contained in plants, it was not until after the investigations of Liebig that our knowledge of the chemistry of plants progressed with any satisfactory degree of rapidity.

CHEMICAL ELEMENTS.

4. All matter is composed of about seventy different chemical elements. A chemical element is any substance which cannot, by any known means, be separated into two or three different kinds of matter. For example, gold is an element, because, in whatever manner it may be treated, we cannot get anything out of it but gold; pure gold contains nothing but gold. So, nitrogen is an element, because, as far as we are able to find out, it contains only one thing, that is, nitrogen. Similarly, carbon, sulphur, potassium, oxygen and iron are elements.

Just as the twenty-six letters of our alphabet are combined in various ways to form the words of a whole language, so these seventy elements or simple substances, constituting nature's alphabet of matter,

are capable of being united to produce all the different chemical compounds that go to make up the countless forms of matter. The number of different combinations possible between these seventy elements is practically infinite.

ELEMENTARY COMPOSITION OF PLANTS.

5. When we state what elements any substance contains, we give its elementary composition. For example, sugar contains the elements, carbon, hydrogen and oxygen; this is a statement of the elementary composition of sugar. So, when we state what elements a plant contains, we give its elementary composition or analysis. The term ultimate composition means the same as elementary composition. We will now consider the elementary composition of plants.

6. The exact number of different kinds of plants growing on the earth has never been definitely ascertained; but the number probably exceeds 200,000. Of this large number, only a few have been subjected to careful chemical analysis, and yet, so uniform in all its great variety are nature's methods of working and building, that we can quite safely say that, so far as the elementary composition of plants is concerned, little remains to be learned. Chemical analysis shows that, of the seventy elements known to exist, only fourteen are essential to produce all the different forms of vegetable life.

While all plants contain certain chemical compounds, such as cellulose, albuminoids, etc., it may be that each plant contains, in some one or all of its parts, one or more chemical compounds peculiar to itself, so that there may be as many distinct chemical compounds in the vegetable kingdom as there are different species of plants. This, of course, cannot be known absolutely until all plants in existence have been carefully analysed; but, whether the number of different chemical compounds in the vegetable kingdom be a few thousand or a few hundred thousand, we know that they are almost entirely made up of fourteen elements, and these, therefore, form the chemical alphabet of the vegetable kingdom, all the different vegetable compounds, like words from letters, being formed by the union of two or more of these elements.

The fourteen elements which are regarded as being necessary to the perfect growth and development of every plant are the following: Carbon, hydrogen, nitrogen, oxygen, phosphorus, sulphur, chlorine, silicon, calcium, iron, magnesium, manganese, potassium and sodium. The element fluorine is of frequent occurrence in very small quantities, and the following elements are of rare or doubtful occurrence: Aluminium, barium, bromine, cobalt, copper, iodine, lead, lithium, nickel, rubidium, tin, titanium and zinc, but their occurrence is a matter of curiosity rather than of practical importance, for, unlike the fourteen named above, they seem in no way to be necessary to plant life.

AIR-DERIVED AND SOIL-DERIVED ELEMENTS.

7. The elements that are necessary to the growth of plants may be divided into two quite distinct classes, which have important and marked differences. These two classes are: (1). Air-derived or organic elements. (2). Soil derived or inorganic elements.

AIR-DERIVED ELEMENTS.	SOIL-DERIVED ELEMENTS.
Carbon.	Phosphorus.
Hydrogen.	Sulphur.
Oxygen.	Chlorine.
Nitrogen.	Silicon.
	Calcium.
	Iron.
	Potassium.
	Sodium.
	Magnesium.
	Manganese.

8. It is usual among writers on agricultural chemistry to call these classes organic and inorganic elements, but this use of these words is extremely inaccurate: for any element may be either organic or inorganic, according as it is or is not a part or product of an organized body. Oxygen, as it exists in the

air, is inorganic matter; but when, through vital processes, it becomes part of an animal or plant, it is organic.

9. These two classes of elements differ in three important particulars, as follows:—

First.—The elements of the first class are derived exclusively from the air, either, directly or indirectly; while those of the second class come exclusively from the soil.

Second.—Air-derived elements disappear, for the most part, in the form of gases, when a plant is burned; while the soil-derived elements, usually the smaller part, are left in the form of a residue or ash, which further heating will not have any effect upon. Some carbon and oxygen and nitrogen are always found in the ash, while slight quantities of chlorine, sulphur and phosphorus are apt to be driven off by heating. The two classes of elements are, therefore, not so sharply defined in this regard as they are in respect to the sources from which they come.

Third.—These two classes differ very noticeably in regard to the quantities in which they are present in plants. Thus, the air-derived elements constitute, at least, ninety-five per cent. of the whole vegetable kingdom, while the soil-derived elements occur in small quantities, varying from a fraction of one per cent. up to ten per cent., or even more in some cases. Because the soil-derived elements occur in so much smaller quantity, it does not follow that their presence is of less importance; in their absence, vegetation would disappear.

We will now consider each of these elements in order, and mention briefly some of the more important characteristics of each; but, before doing this, it is desired to explain the meaning of two or three chemical terms which we shall have occasion to use.

ACID-FORMING ELEMENTS AND METALS.

10. Of the fourteen elements which are found in plants, some are spoken of as non-metallic elements or acid-forming elements, because, in certain combinations, these elements form well-known acids. The other elements are known as metallic elements or metals.

ACID-FORMING ELEMENTS.	METALS.
Carbon.	Calcium.
Hydrogen.	Potassium.
Oxygen.	Sodium.
Nitrogen.	Iron.
Phosphorus.	Magnesium.
Sulphur.	Manganese.
Chlorine.	
Silicon.	

ACIDS AND SALTS.

11. An acid is a compound containing an acid-forming element combined with hydrogen and oxygen, or, in some cases, with hydrogen alone. The following examples will serve to illustrate:—

Nitrogen, hydrogen and oxygen form nitric acid; phosphorus, hydrogen and oxygen form phosphoric acid; sulphur, hydrogen and oxygen form sulphuric acid; chlorine and hydrogen form hydrochloric acid. The common name of sulphuric acid is oil of vitriol; the common name of hydrochloric acid is muriatic acid.

12. A salt is a compound formed by putting a metal, in the place of the hydrogen of an acid; that is, a acid differs from a salt simply in having a metal where the acid has hydrogen. Every acid has a salt corresponding to it. For example, as stated above, nitric acid consists of nitrogen, hydrogen and oxygen. Now, if we put the metal potassium in the place of hydrogen, we have a compound containing nitrogen, potassium (in place of hydrogen) and oxygen. This compound is the potassium salt of nitric acid and is called potassium nitrate, or, sometimes, nitrate of potash. Again, phosphoric acid consists of phosphorus, hydrogen and oxygen; in place of hydrogen, put one of the metals, as calcium, and we have a compound containing phosphorus, calcium (in place of hydrogen) and oxygen, which is the calcium salt of phosphoric acid and is called calcium phosphate, or, sometimes, phosphate of lime. Similarly, if a metal, as magnesium, is put in the place of the hydrogen of sulphuric acid, we have the magnesium salt of sulphuric acid, or magne-

sium sulphate familiar to us as Epsom salt. If in hydrochloric (muriatic) acid, we put some metal, as sodium, in place of the hydrogen, we have a compound consisting of sodium and chlorine, which is the sodium salt of hydrochloric acid and is called sodium chloride, sometimes muriate of soda, familiar to us as common salt.

The word "salt," as used in chemistry, applies to a great number of compounds, and many of the substances we have to deal with in speaking of fertilizers are chemical salts, that is, substances formed by putting some metal in place of the hydrogen of some acid.

CARBON.

13. IMPORTANCE OF CARBON.—The element, carbon, may be called the central element of all animal and vegetable substances; for there is not a living thing, from the smallest cell to the giant tree, which does not contain carbon as a necessary constituent. That all vegetable and animal substances contain carbon can easily be shown by simply heating them sufficiently, and thus causing them to blacken or char. When, for example, wood is heated, the different elements of which it is composed, are driven off in one form or another, but the carbon is the last to go, and remains behind as a black substance or charcoal, unless heated higher, when it disappears or burns up.

14. OCCURRENCE OF CARBON IN NATURE.—Carbon usually occurs in nature united into compounds with other elements. Thus, most products of plant life contain carbon combined with the elements hydrogen and oxygen; such are starch, sugar and cellulose or woody fibre. Carbon, combined with oxygen, occurs in the air in the form of carbon dioxide, commonly called carbonic acid gas. Carbon, when combined with oxygen and some element such as calcium, occurs in the form of carbonates; for example, marble, limestone and chalk are chemically known as calcium carbonate or carbonate of lime.

Carbon by itself or in the free condition, that is, not united with any other elements, is familiar to us in several different forms; the most common of these forms are (1) diamonds; (2) graphite, which is used in the manufacture of lead pencils; (3) ordinary wood charcoal; (4) lamp-black; (5) animal charcoal; (6) mineral coal. Excepting diamonds these forms of carbon are more or less impure, containing some other things mixed with the carbon.

15. It is pertinent to make here the inquiry, "What is the relation of carbon to fertilizers?" Before we can answer this question satisfactorily, we must know what is meant by a fertilizer and what must be regarded as necessary constituents of a fertilizer. We will, therefore, turn aside from our consideration of the element carbon and take the opportunity, at this stage, to give some definitions of general and special terms which we shall have occasion to use more or less frequently.

DEFINITIONS.

16. FERTILIZER.—As ordinarily spoken of, a fertilizer may be defined as any substance which, by its addition to the soil, is intended to produce a better growth of plants.

The materials which come under the head of fertilizers are numerous in kind, and different both in form and in the manner in which they act.

17. The following tabulated classification, while not strictly accurate in every respect, will serve to give a good general idea of the number and relations of the terms used in speaking of fertilizers:—

FERTILIZERS.	{	I. Direct	{	1. Natural	Stable manure.
					Refuse vegetable matter.
				2 Artificial	Green Crops for plowing under.
					Cotton Seed. Muck, marls, etc.
II. Indirect	{	{	a. completo or general,	Commercial	
				Chemical,	
			b. incompleto or special.	Prepared.	
				Lime. Gypsum. Salt, etc.	

These terms are, in general, loosely and indiscriminately used, as their meaning is often misunderstood; and so an attempt will be made here to define them in accordance with the best usage of the terms.

18. A direct fertilizer is one that contains elements of plant food which are available at once, that is, which can be taken up and used immediately by plants.

19. The term available is applied to plant food which is soluble, that is, in such a condition that the roots of the plant can take it up readily in solution.

20. Plant food is unavailable when it is in an insoluble form, so that the roots of the plant fail to take up any part of it. A large proportion of plant food present in the soil is unavailable, but, by the action of air, water, carbonic acid, etc., it is gradually changed to soluble or available forms, which the plant can take up and use. As will be noticed later, phosphoric acid in the form of insoluble calcium phosphate, or phosphate of lime, is unavailable as plant food, but when converted into a super-phosphate, or soluble calcium phosphate, it becomes available. Unavailable plant food is potential food or food in reserve.

21. An indirect fertilizer is one which does not furnish to the soil any needed plant food and which may not be a plant food at all, but which is characterized by the way in which it acts on the matter already in the soil, changing more or less of it from unavailable plant food to an available form. For example, lime, gypsum, salt, etc., are indirect fertilizers, so far as they have any fertilizing action. Later, some attention will be given to the action of some of the most familiar indirect fertilizers.

22. Natural fertilizers include the solid and liquid excrement of animals, all kinds of vegetable refuse, green crops for plowing under, cotton seed, mucks, marls, etc.

23. Artificial fertilizers are also known by such names as commercial fertilizers, chemical fertilizers, prepared fertilizers, etc., and are artificial preparations or mixtures of fertilizing materials sold under trade names. The fertilizing materials used in making these mixtures include the substances found in natural deposits and by-products of numerous industries, which are obtainable by farmers only through the channels of trade. Some substances which might be classed as natural fertilizers, such as cotton-seed meal and tobacco stems, are also included among the materials of artificial fertilizers.

24. Complete fertilizers, known also as general fertilizers, are those which contain nitrogen, phosphoric acid and potash.

25. Incomplete fertilizers, also called special fertilizers, are those which contain only one or two of the three constituents, nitrogen, phosphoric acid and potash.

26. There is a common practice among farmers and dealers, of calling all commercial fertilizers "phosphates," regardless of whether they contain any phosphates at all or not. The practice is clearly objectionable, because a phosphate is not the only fertilizing constituent present in commercial fertilizers—in some cases it may be entirely absent. The term "super-phosphates" applies truthfully to many commercial fertilizers, but even these cannot be correctly spoken of as simply "phosphates."

Having considered such definitions as we may have occasion to use more or less frequently, we can now return to

THE RELATIONS OF CARBON TO FERTILIZERS.

27. We know that carbon must be an important element in plant food, since it forms nearly one-half of the solid proportions of plants. Notwithstanding the fact that carbon forms so large a portion of plants, it has no importance as an active food constituent of direct fertilizers. This statement may appear strange and the question may be asked, "Why is not carbon to be regarded as an essential constituent of direct fertilizers?" The answer is that the carbon of plants comes from the carbon dioxide (carbonic acid gas) of the air, and the air furnishes an inexhaustible and available supply of this substance;

We do not, therefore, need to add carbon to the soil. However, as we shall notice later, some forms of carbon possess value as indirect fertilizers.

HYDROGEN.

28. OCCURRENCE IN NATURE.—The element, hydrogen, is nearly always found uncombined with other element. It combines with oxygen to form water. Hydrogen also occurs in most animal and vegetable substances, such as various kinds of wood, fruits, etc., when it is combined with the elements, carbon and oxygen. Hydrogen is always present in all kinds of acids.

29. DESCRIPTION OF HYDROGEN.—Hydrogen, in the uncombined form, is a gas that resembles air in that it has neither color, smell, nor taste.

OXYGEN.

30. OCCURRENCE OF OXYGEN IN NATURE.—Oxygen is the most abundant of all the elements. The compounds which contain no oxygen are few in number. Oxygen forms nearly one-half of the crust of the earth; eight-ninths of water; about one-fifth of air, and one-third of all animal and vegetable matter.

Oxygen occurs in the air uncombined with other elements. Oxygen, combined with the elements carbon and hydrogen, or with carbon, hydrogen and nitrogen, is found in substances which go to make up animals and vegetables.

31. DESCRIPTION OF OXYGEN.—As might be inferred from knowing that oxygen in the uncombined state forms part of the air, oxygen has no color, taste or smell.

Oxygen is a very active substance from a chemical point of view. It tends to unite with nearly all of the other elements. In all forms of burning, the oxygen of the air is simply uniting with other elements. Thus, in a coal fire the oxygen unites with the carbon of the coal. The heat is produced by the union of the two.

THE RELATIONS OF HYDROGEN AND OXYGEN TO FERTILIZERS.

32. As already stated, water is formed by the union of two gases, hydrogen and oxygen. These elements are supplied to plants in the form of water. Growing plants contain a larger amount of water than of any other constituent. The oxygen and hydrogen of the water are separated in the plant, and in this way plants secure the hydrogen and oxygen which they need to build up their tissues. In this manner water acts as a direct fertilizer. The water is supplied by rains to the soil, from the soil it is taken into the plant through the roots. In regions adapted to agriculture, plants receive all the hydrogen and oxygen needed, and usually much more, from the rains. Therefore, these elements are not considered important parts of fertilizers, except, perhaps, that it is desirable to have in a commercial fertilizer as little water as possible.

When water is supplied to plants by irrigation, it can very properly be called a fertilizer, and an extremely important one, too.

35. In addition to its action as a direct fertilizer, water has an important part to play as an indirect fertilizer. Thus, it dissolves the soluble food materials of the soil, the mineral matter and most of the nitrogen, and carries them into the plant. In addition to its action as an indirect fertilizer, water acts as a carrier within the plant in transferring from one part of the plant to another, as needed, the various products contained in the plant, just as the blood in the animal body carries to every part the nutrient adapted to each organ and part.

NITROGEN.

31. OCCURRENCE OF NITROGEN.—Nitrogen occurs in nature in the following forms:—

- (1). As a constituent of air.
- (2). In the form of ammonia.
- (3). In the form of nitric acid and nitrates.
- (4). In various other forms in plants and animals.

35. NITROGEN IN AIR.—Nitrogen, uncombined with other elements, forms about four-fifths of the air. Since the nitrogen in the air is not combined, we

can conceive its properties for ourselves, and our observations show us that it is a gas, which has neither color, taste, nor smell.

36. NITROGEN IN AMMONIA.—Nitrogen combined with the element hydrogen forms ammonia. Ammonia is present in the air in very small quantities. Ammonia is formed when vegetable and animal substances containing nitrogen decompose.

Ammonia is a colorless gas, and it is this gas dissolved in water which is familiar to us as ammonia water, or "spirits of hartshorn," and which causes the peculiar odor of "hartshorn."

Ammonia unites with different acids and forms salts, much as acids do; these salts we call ammonium salts, compounds which do not generally have any odor like ammonia. Thus, ammonia combined with sulphuric acid forms ammonium sulphate, called by some, sulphate of ammonia. Ammonia combined with hydrochloric acid forms ammonium chloride, sometimes called muriate of ammonia, also known as sal-ammoniac.

37. NITROGEN IN NITRATES.—Nitrogen, combined with hydrogen and oxygen, forms nitric acid or *agua fortis*. If in nitric acid a metal, as sodium, for example, takes the place of hydrogen, we have a sodium salt of nitric acid, or a nitrate, formed, called sodium nitrate.

When animal or vegetable substances decompose in rather warm, moist places, the nitrogen is changed into nitrates. This change of the nitrogen of organic matter into nitrates is caused by bacteria, which are very small living vegetable organisms, and which exist everywhere in enormous numbers. The process is known as "nitrification."

38. NITROGEN IN ANIMALS AND PLANTS, OR, ORGANIC NITROGEN.—Nitrogen, combined with the elements, hydrogen, carbon and oxygen, occurs in plants and in animals. Such substances, for example, are the casein or curd of milk, the gluten or gummy portion of wheat, the fibrin of blood, the white of egg, etc. When such compounds decompose, the nitrogen is first changed into ammonia, and then, under proper conditions, into nitric acid or nitrates. The nitrogen existing in animals and plants is generally spoken of as organic nitrogen.

IN WHAT FORMS IS NITROGEN USEFUL TO PLANTS?

39. Plants can use nitrogen in three different forms, viz:—

- (1). As nitrogen gas or uncombined nitrogen.
- (2). In the form of ammonia.
- (3). In the form of nitrates.

All plants cannot use nitrogen in any of these three forms equally well, but each form is found specially suited to certain kinds of plants, as will be noticed.

40. NITROGEN GAS USED BY PLANTS.—Although we have nitrogen gas, or uncombined nitrogen, existing in the air in enormous quantities, still, the number and kinds of plants which can use the nitrogen of the air is not large. In general, those plants which are called leguminous, such as the bean, pea, clover, alfalfa, etc., can take uncombined nitrogen from the air.

41. NITROGEN OF AMMONIA USED BY PLANTS.—The leaves of some plants have the power of absorbing ammonia directly from the air and obtain nitrogen in this way. Some plants obtain nitrogen from ammonium salts through the soil.

42. NITROGEN OF NITRATES USED BY PLANTS.—The largest part of the nitrogen which most plants obtain is taken up by their roots from the soil in the form of nitrates; that is, nitric acid combined with some metal, as sodium or potassium. As already stated, most of the nitrates used by plants are formed by changing into nitrates ammonia compounds and organic substances in the soil by the process called nitrification. Hence, nitrogen, in the form of nitrates, is the most available form for most plants; that is, it can be most readily taken up and used by plants.

RELATIONS OF NITROGEN TO FERTILIZERS.

43. Experiments have shown that nitrogen is essential to the growth of plants; that the quantities of nitrogen available as plant food are very small;

that nitrogen is one of the first elements in the soil to be used up; that, of all the fertilizing elements, nitrogen is and always has been the most expensive.

THE SPECIFIC ACTION OF NITROGEN UPON PLANTS.

47. The influence of nitrogen in its various forms upon plant growth is shown by at least three striking effects.

First.—The growth of stems and leaves is greatly promoted, while that of buds and flowers is retarded. Ordinarily, most plants, at a certain period of growth, cease to produce new branches and foliage, or to increase those already formed, and commence to produce flowers and fruits, whereby the species may be perpetuated. If a plant is provided with as much available nitrogen as it can use just at the time it begins to flower, the formation of flowers may be checked, while the activity of growth is transferred back to and renewed in stems and leaves, which take on a new vigor and multiply with remarkable luxuriance. Should flowers be produced under these circumstances, they are sterile and produce no seed.

Second.—The effect of nitrogen upon plants is to deepen the color of the foliage, which is a sign of increased vegetative activity and health.

Third.—The effect of nitrogen is to increase, in a very marked degree, the relative proportion of nitrogen in the plant.

LOSS OF NITROGEN COMPOUNDS.

45. Since ammonia compounds and nitrates dissolve easily in water, is there not danger of their being carried away in drainage water from the upper soil out of reach of the plants?

Experiments have been made to settle the question, and results indicate that ammonia compounds are largely retained in the soil. Nitrates are apt to be washed out and lost in the case of bare fallow land; but when the soil is covered with vegetation there is little or no loss, for the reason that the roots of growing plants absorb nitrogen very readily. Some nitrogen is also lost by organic matter in the process of decay, escaping into the air as free nitrogen.

These losses of nitrogen are, to some extent, replaced naturally by means of the nitric acid and ammonia dissolved by the rain and dew, also by organic matter decaying at the surface of the soil, and also by conversion of the free nitrogen of the air into some form which the plant can take up and use. These natural additions of nitrogen do not usually make good on the farm the losses, and in time the nitrogen becomes insufficient to produce paying crops without the addition of nitrogenous manures.

We shall notice later the various forms of nitrogen ordinarily used in commercial fertilizers.—*Bulletin of the New York Agricultural Experiment Station.*

SOME POINTS IN PRACTICAL FORESTRY.

In an interesting review, by Dr. Brandis, of Dr. Schlich's "Manual of Forestry," published in a recent number of *Nature*, attention is called to the fact that this book was prepared by the author primarily for the use of the students at the Cooper's Hill Forest School in England. That school was established seven years ago, in connection with the Royal Indian Engineering College, in order to give the needed professional training to young Englishmen who desired to enter the Indian Forest Department. When the first volume of this handbook appeared some persons, who took a deep interest in the progress of forestry in the British Indian Empire, were surprised that it did not deal with Indian trees, but that its teaching were illustrated by the Oak, the Beech, the Scotch Pine and other trees of Europe, and the book was, therefore, pronounced by them a failure. But the principles of silviculture are the same everywhere, and the application of these principles to the treatment of different woods in different parts of the globe will lead to the adoption of similar methods; and, therefore, according to Dr. Brandis, the author of the manual was right in selecting the timber trees of

Europe to illustrate these principles and the practice based upon them, because those trees are at hand for example, and because the systematic treatment of European forests is of long standing, and has endured the test of experience, while the methodical care of Indian forests is not more than thirty-five years old. As an interesting example of the way in which similar practices have developed in the rearing and tending of woods in Europe and in India, we quote the following parallel from Dr. Brandis' review:—

In a loop of the Main River, in Lower Franconia, east of Aschaffenburg, rises an extensive mountainous country, clothed with almost unbroken forest of singular beauty and of enormous value. It is the Spessart, in old times known as the home and haunt of great highway robbers, but also known from time immemorial as the home of the best Oak timber in Germany. The red sandstone of the Trias, which everywhere is the underlying rock in this extensive forest-country, makes a light sandy loam, which, where deep, is capable of producing tall, cylindrical, well-shaped stems. Having grown up, while young, in a densely crowded wood, the Oak here has cleared itself of side branches at an early age. Hence these clean straight stems which, in the case of Spruce, Silver Fir, and other forest-trees, may justly be said to be the rule, but which the Oak does not produce, save under these and similarly favourable circumstances. The species here is *Quercus sessiliflora*; this species does not form pure forests, but is always found mixed with other trees, the Hornbeam, the Beech, and on the lower slopes of the western Schwarzwald, the Silver Fir. In the Spessart, the Beech is associated with the Oak in the same manner as the Bamboo is the chief associate of the Teak-tree in Burma.

The principles which guide the forester in the proper treatment of his woods are the same in India as in Europe. In the Teak-forests of Burma the Bamboo has a position similar to that of the Beech in the Oak-forests of the Spessart. Oak and Teak are both trees with comparatively light foliage. Pure woods of these species, while young, are sufficiently dense to shade the ground, whereas at an advanced age the wood gets thin, the canopy light, and the result is that grass and weeds appear, and that by the action of sun and wind the soil hardens and is less fertile than the loose porous soil, which is shaded by dense masses of foliage. Hence the advantage of associates, which, like the Beech in Europe and the Bamboo in Burma, shade the ground with their dense foliage, and enrich it by the abundant fall of their leaves. But it is not only the condition of the ground which is improved by these useful associates. Teak and Oak have this specially also in common, that, when growing up alone, their stems, instead of running up into clean cylindrical boles, are apt to throw out side branches, which greatly impair the market value of the log. But when growing up in dense masses with their natural associates, these latter, crowding in as they do on all sides around the Oak in the Spessart and the Teak in Burma, prevent the development of side branches, and thus produce clean and regularly shaped stems.

In these and many other ways are the associates of the Teak and of the Oak useful friends, so to speak. Under certain circumstances, however, and at certain periods of their life, they are dangerous enemies to their more valuable companions. On the sandstone of the Spessart, and elsewhere, the Beech, as a rule, has a more vigorous growth than the Oak; it gets the upper hand, and, unless it is cut back or thinned out in time, the Oak, if both are growing up in an even mixture, has no chance. The Bamboo is even more formidable as an enemy of the young Teak-tree. Though the Teak may have had a long start, if a crop of Bamboos—either the shoots of old rhizomes, or, perhaps, the result of several seedings of the old Bamboo-forest, clear away to make room for the Teak—spring up among it, the Teak is doomed. As soon as the rhizomes of the Bamboo have acquired sufficient strength, they produce, within a few weeks, during the rains, such a profusion of full-sized shoots, say twenty to thirty feet high, that the young Teak-trees among them are throttled and extinguished.

The similarity in the relations of Teak and Bamboo in Burma, and of Oak and Beech in the Spessart, has led foresters in both countries to devise similar arrangements for the regeneration of those forests. In the Spessart, when the old timber in a compartment of the forest is cut, the best places for the growth of the Oak are selected, and the Oak, which here sells at the rate of from two shillings to three shillings a cubic foot for sound and well-shaped pieces, is sown on soil most suitable for its development; while the Beech, the timber of which only fetches about one-fifth of that amount, is allowed to reproduce naturally from self-sown seedlings over the rest of the area. Among the Oak also a certain but small proportion of Beech springs up, and even where pure Oak woods may be the result of these proceedings, it will not be difficult, when they are sufficiently advanced, to introduce such a proportion of Beech as will secure their satisfactory development. In the same way in Burma, selected areas are cleared for the growth of Teak in the original forest, the clearance being effected, and the Teak planted, with the aid of that rude mode of shifting cultivation, known as the *Toungya* system.—*Garden and Forest*.

DATURA STRAMONIUM, *Linn.*

"THORN APPLE," "STINK WEED," "DEVIL'S TRUMPET."

A coarse, weedy annual, sometimes attaining a height of 3 or 4 feet. The leaves are very unequal in size—the larger ones often 8 or 9 inches long, ovate in outline, rather flaccid, the margin undulated, and deeply indented with large, irregular incisions, forming unequal spreading teeth. Flowers, solitary, and shortly stalked, corolla funnel-shaped, white, 3 to 4 inches long, and about 2 inches wide at the mouth, with five spreading or recurved lobes. Stamens, five, inserted in the corolla tube, and included in it. Fruit, about 2 inches long, thickly set with unequal, sharp, rigid spines. The thorn-apple is considered by De Candolle to be indigenous to the countries bordering the Caspian. It is now spread as a weed nearly all over the warmer and temperate parts of the earth. In this Colony the seedlings generally spring up in September or October, and continue growing till April or May, when the plants usually die out, although I have seen them growing occasionally in winter, but only in very sheltered situations. In many places—but principally in the coastal districts—the plant may be seen growing plentifully during the summer months. When growing in pastures it is really a dangerous weed, for I have known it to poison milk cows that have partaken of it, and no pains should be spared on the part of any one who keeps cattle to exterminate it from grazing lands. When it is allowed to grow undisturbed for a time it produces a phenomenal quantity of seed, which will, when ripe, germinate readily any time during the summer months, whilst there is moisture in the soil, so that the area of its occupation gradually widens from year to year. The very same thing takes place with many other introduced weeds, especially those from the northern parts of Europe, and America; and, although they may be strictly annual in those countries, often, in a good season here, they will produce three or four successive crops from seed ripened at different times in the same year, so that our cultivators sometimes have to war against annuals, almost as much as if they were perennials.

I have very often given the leaves of the "thorn-apple plant" to persons suffering from asthma, and recommended them to smoke it—but with caution, and not too often—as they would tobacco, and when they have done so it has given them great relief. When used for this purpose the leaves should be partially dried in some place away from the influence of the sun's rays. Bailey and Gordon (Queensland) include the "thorn-apple plant" in their "Plants Reputed Poisonous and Injurious to Stock," and say that "the plant is decidedly poisonous." Much com-

ment was made in this and the adjoining colonies about a notice of the thorn-apple plant published in the *Sydney Mail*, 5th April, 1890, by J. H. Malden, of the Technological Museum, Sydney. The writer said, amongst other things, that "the plant has a disagreeable taste, and cattle will not touch it, so that stock-owners need have no anxiety about it." To this statement Mr. P. R. Gordon, Chief Inspector of Stock, Queensland, wrote the following letter to the Editor, *Sydney Mail*, and it was published on the 19th April, 1890:—"In the notice of the above-mentioned plant in your issue of 5th April, Mr. J. H. Malden says 'that cattle will not touch it, so that stock-owners need have no anxiety about it.' In this Mr. Malden is entirely wrong. Quantities of this plant grow in the neighbourhood of Toowoomba, and there have been many deaths in cattle from eating it. These deaths have not been mere cases of surmise. When the Board of Inquiry into 'Diseases of Live Stock and Plants' (of which I was *ex-officio* secretary) was in existence in this Colony, the stomachs of several cattle that had died in paddocks close to Toowoomba were forwarded to the Board, and analyzed by the late Karl T. Staiger, then Government Analyst, and in each instance the analysis showed death to have been occasioned by the animals having eaten the thorn-apple plant. It may be remarked that in each instance the poisoning was confined to quiet milking cattle, and it will be found, as a rule, that mortality from poisonous plants is confined to quiet milkers, or their progeny. These pet animals will nibble at and eat plants that ordinary bush cattle will not touch, unless forced to do from sheer starvation."

The following extract is from Bentley and Trimen's *Medicinal Plants*:—"The activity of both the leaves and seeds of *Datura stramonium* are due to the highly-poisonous alkaloid *daturia* or *daturine*; and although we have no chemical proof of the existence of this alkaloid in the other species of *datura* alluded to under the head of substitutes, its presence in them can scarcely be doubted . . . according to Schroff, *atropa* has twice the poisonous energy of *daturia*; whilst Jobert, again, regards *daturia*, when applied to the eye, as about three times as powerful as *atropa*, and more constant and lasting in its operation. . . The properties of *stramonium* are regarded as anodyne and antispasmodic, and, in overdoses, a powerful poison. It has been found useful in neuralgic and rheumatic affections, in gastrodynia and other painful diseases, and some have regarded it as a very valuable remedy in mania and epilepsy, but in these diseases it not infrequently produces injurious effects. When used during paroxysms of spasmodic asthma it commonly gives temporary relief, and facilitates expectoration. In the latter disease, and also in dyspnoea, catarrhs, and in other cases, the leaves are generally smoked, like tobacco, or inhalation from their infusion in warm water is resorted to. But its use in these ways requires caution, as it has proved highly injurious, and, in some instances, fatal. In Cochin China a strong decoction of the leaves is regarded as a very efficacious remedy in hydrophobia."

The Rev. Dr. Wools, F.L.S., informs me that a child died near Richmond from swallowing the seeds of *stramonium*.—*Agricultural Gazette*.

GEMMING AND MINING OF CEYLON.

Searching for gems is obviously a very precarious industry, which has hitherto yielded more blanks than prizes. To the long list of undertakings which have been formed and worked apparently with the object of proving this point may be added the one whose title heads these remarks. Why precious stones should elude the vigilance and science of the expert miner, when backed with any amount of capital applied by the British investor, is the more singular because such things are said to literally jump into the laps of the natives, who have neither science to guide them in their search nor money wherewith to decay the precious treasures from their hiding places. This is a matter we have recognised for a long while past, and we

sought to enforce it when the Gemming and Mining Company of Ceylon came forward. This undertaking cannot be said to have come out under the best or most favourable auspices. That goes without saying when we mention that it was promoted by the celebrated Gold Trust and Investment Corporation, which promoted at about the same time

THE NOTORIOUS PERSIAN INVESTMENT CORPORATION,

in both of which it prided itself on retaining a considerable interest, though to what extent that retention was voluntary or enforced, and in what measure the pride may still survive, we need hardly wait to inquire. The saying that pride goes before a fall has, however, been pretty well exemplified in the case of these two undertakings. The history of the rise and fall of the Persian Investment Corporation is too fresh in everybody's mind to need recapitulation. The like story of the Gemming and Mining Company still remains to be told, though it has not yet reached the stage when that can be done with true dramatic effect. The latter company was formed in December, 1889, with an authorised capital of £100,000 in shares of £1 each, to acquire certain freeholds consisting of 1,280 acres of land, situated in Rakwana district, Ceylon. The mining rights of the Rangweltenne and one or two other estates were also acquired, subject to the payment of certain rents and royalties. The purchase price of the whole show was fixed at £50,000, payable as to £12,500 in cash, and the rest in shares or cash and shares. Looked at from the point of view of

THE EXPERT REPORTS

on the business there was nothing about those terms at which anybody could cavil. A Mr. C. E. H. Symons, and a Mr. Charles Sband, of Colombo, were the two chief witnesses to the untold wealth of the property, and those two gentlemen brought to bear in support of their right to speak with unquestionable authority on the subject, the two important qualifications that the first had for many years past "taken a great interest in the search for precious stones as carried on by the natives," while Mr. Sband and wife, represented by a trustee, figured in the contracts for the sale and purchase of the affair. One of the estates to be acquired, namely, the Everton, was said by Mr. Symons to have been famous for its gems for the last 30 or 40 years. The sapphires had a purity and depth of colour which were proverbial. Outcrops of the highest value had been found "in quantity." Then there were terracine, amethyst, topaz, common and star stones, and all the rest of it. Corundum could be

FOUND BY THE TON,

and also crystals of remarkable size and "purity of whiteness," which, for "optical purposes are unsurpassed." These crystals could, of course, have been utilised as lenses with which to enable the shareholders at a later date to scan and decipher their dividend warrants, though they have not been adapted to that purpose yet. But more important than all this vast show of wealth was the fact that there "were from 50 to 60 pits sunk in Kabragallakelle" (in comparison with which the mystic word *Abra-cadabra* sounds mean), "which exist to this day." We say "more important than all," because there was no knowing at the time to what untold uses these pits might be put at a later date in the way of storing the gems or, at the worst, burying the hopes of the shareholders. The latter seems, at the present moment, likely to be their most immediate use. The property being of such large extent the directors, said the prospectus, "may consider it advisable to dispose of part of the estates to other companies," but no such companies have come along to mar the enjoyment of

SEARCHING ALL ALONE FOR THE GREAT WEALTH

supposed to lay buried in the undertaking. The second ordinary meeting was held on Thursday, and the chairman said he regretted the report was not more favourable. The pits, there is every reason to believe, are in their old places, but the capital is not. That, said the chairman, was "steadily going,"

so the affair can scarcely be said to be in every particular at a standstill, and it was for this reason perhaps, that he sought to impress on the shareholders that they "should not lose heart." The land where they were carrying on operations was honey-combed with tunnels and burrows made by the natives for generations past, but the people engaged to look after it had only got the worst stones, the explanation volunteered for this being that the native miners were "too many for them." The best mining experts in Ceylon had been engaged to explore and survey the property, and these had all wound up their experience by telling the company to "go on and prosper," which was very handsome of them, though it would not have been amiss if they had at the same time given a hint how

THE PROSPERING PART OF THE BUSINESS

was to be accomplished. In the absence of such information the company has been unable to carry out the recommendation. "We could not do so," said the chairman, because the capital, as already remarked, is steadily going, "and they did not seem to be getting what they contemplated they would get." A shareholder asked if they had let any of the gem land, to which there was vouchsafed the reply that "they had not, but that they contemplated doing so." In view of the glowing description of the property with its 50 to 60 pits, and the diggings and burrowings, and the precious stones, etc., that was a somewhat singular, not to say startling, confession to make, and it is surprising the shareholders did not show a little more interest to learn on what they were working all last year simply to lose close upon £1,000. They have on the way home 7½ owt. of corundum, which said the chairman, is the "mother of sapphires," though, as a matter of chemical fact, it is a crystallised state of alumina, of which sapphire, ruby, amethyst, etc., are others; but they have not found any gems. What the directors will do with the alleged "mother of sapphires" we do not profess to know, unless it be to force her to yield progeny. That, at all events, seems to be the only way in which this Gemming and Mining Company of Ceylon is likely to make anything. A subsidiary company for breeding sapphires would not be a bad notion and we commend it, for what may be worth, to certain members of the promoting fraternity.—*Daily Oracle*, Oct. 17th.

NETHERLANDS INDIA.

Dr. Karsten, a botanical expert, calls attention to the extraordinarily high percentage of tannin in plants growing on marshy land near the seaboard throughout the Indian Archipelago. He deems that these plants find in their tannin a preservative from the decomposing influences arising out of their unfavourable environment, and he strongly recommends their bark for tanning purposes in Europe. He points out that the mangrove is used in South America as dye and tanning material. The barks of the mangroves found in Java are used for tanning and dyeing but are not exported to Europe.

Advices from the sugar, coffee, and indigo estates in E. Java are far from encouraging owing to the long continued drought.

The *Batavia Nieuwsblad* says that quinine has been put to a new use as antidote against the opium habit. It is reported that natives given to opium and wishing to leave it off need only use quinine water, and that this remedy takes good effect on them.—*Straits Times*.

PLANTING NOTES FROM THE NILGIRIS.

(From our own Correspondent)

COONOOR, Nov. 1.—The drought of August and September was followed by excessive rain in October. Between the 1st and 30th of last month the fall here has been over 55 inches; such heavy rain has not been known on the Nilgiris for the last 30 years.* Those abnormal showers have done a great deal of damage to estates in and near Coonoor; numerous landslips have taken place, especially on steep estates, and

* We should think it is unprecedented. A year's average rainfall in one month.—*Ed. T. J.*

thousands of fine coffee trees laden with crop, most of which would have ripened in another week or two, were completely washed away, leaving ugly gaps on what was but a short time ago splendid and unbroken fields of healthy coffee. The wet weather during October has prevented the crop from ripening. Most of the planters on the slope of the Nilgiris anticipated an early crop this year, in consequence of the blossom having come out in February or a month earlier than usual. In September picking commenced, and if we had had the ordinary October weather we would have been in the height of the picking season by this time; but with such weather as we had, all rain and no sun, very little crop was gathered during last month. A couple of weeks at least of dry weather is wanted to bring on the crop. In your issue of the 29th ultimo "Planter" attributes the recent floods on the Coonoor Ghant to atmospheric disturbances caused by continuous blasting on the Nilgiri Railway works, and to establish this theory he says that the last recorded floods took place in 1868 during the construction of the new Ghant road. I shall express no opinion as to the effect blasting may have with regard to rain, but the heavy rains in 1868 came down after the Ghant road was completed. During last February, when there was no blasting going on, we had very abnormal weather, from 14 to 20 inches of rain having fallen in different parts of Coonoor, the average fall in previous years during that month being from 1 to 2 inches. To what will "Planter" attribute the February rains?—*M. Mail.*

THE PLANTERS, THE TEA FUND AND THE CHICAGO EXHIBITION SPECIAL SUBSCRIPTION.

We regret to learn that defections of contributors to the Tea Fund continue. Some, we fear, are only too glad to find an excuse for ceasing to pay; but we are glad to hear that others are giving to the special Chicago subscription the equivalents of what they previously contributed to the Fund. They really ought to give more; for those of us who have continued to subscribe to the Tea Fund (in increased ratio proportionate to increase in crops) will be expected to contribute also to the special fund. Mr. Wm. Mackenzie is more sanguine than we are about the special subscription, for we fear that arguments impeaching the conduct of the directors of the Tea Fund with reference to that unhappy Tea Company will be deemed more conclusive by many than appeals to their patriotism, their duty and even their prospective self-interest in favour of liberal subscriptions to the Chicago fund. Nothing will please us better than a result which will shame our doubts and negative our fears. We hear of an address to proprietors of estates in the great district of Dimbula, which is to be attacked in divisions by collectors, with the hope that £25,000 will be thus realized! The idea is not so extravagant as it seems, for the district of Dimbula is believed to comprise one-sixth of all the tea in the island. If Dimbula contributed the sum mentioned and other districts gave in proportion, the sum of £15,000 would no doubt be realized. We feared we were going beyond our tether when we put £10,000 before the planters as a sum to aim at, but the larger amount can be contributed, and if it is available it can be all most usefully and *reproductively* spent in making our tea and its merits known not only in America but amongst the many nations, peoples and languages, representatives of which will assemble at the World's Fair. We sincerely trust that all misunderstandings, jealousies and even differences of opinion amongst all interested in Ceylon tea

will be laid aside in favour of earnest and united efforts towards of a really good and effective appearance of our great staple at the Chicago Exhibition. A long pull and a strong pull and a pull altogether, and new markets for Ceylon tea will be conquered so as to banish the huge bear of "OVER-PRODUCTION" which now is so ominously portrayed on the canvas of our future.

HOP TEA.

A number of gentlemen interested in the tea trade and representatives of the Press were invited on Thursday to inspect the factory at Maidstone of the Hop Tea Company. Upon their arrival Mr. H. A. Snelling (the patentee of the process) at once proceeded to explain the various methods by which the hops are prepared for admixture with various blends of tea. In the first instance, he stated, they are allowed to wither. This is effected by placing them on rows of wicker trays with half-inch webbing, thereby allowing a current fresh air to continually pass through them. The hops are then passed under powerful rollers. Fermentation is thus produced. This fermentation has the effect of modifying and partly destroying the bitterness of the hop, and at the same time darkening the liquor produced therefrom. The next stage is to take the hops by the "Sirocco" system. Mr. Snelling claimed that by the introduction of hops prepared by his patents not only in the flavour of the tea improved, but hop being a sedative it counteracted the too exciting effect of tea upon the nerves. Further than this, it modified the undesirable astringency of ordinary tea. He also stated that since the establishment of the company hop tea had been growing greatly in favour, and that this success had led to the formation of a syndicate for acquiring the Foreign and Colonial patents.

Subsequently a luncheon was given, at which the Mayor of Maidstone presided. Mr. Mathew A. Adams, F.R.C.S., F.I.C., F.C.S., in the course of the subsequent proceedings, said that a chemical analysis discovered in hops an unusual abundance of alkaloid Theine, the substance to which tea owed its valuable properties as a food, giving tranquility in nervous excitement, and, by some wonderful means, while preventing waste of nervous energy, promoting intellectual activity. He expressed a confident opinion that hop tea would be a great boon to many persons who for various reasons were not able to take ordinary tea.—*Daily Oracle.*

TEA TRADERS' TALK.

[Under this heading the *American Grocer* is publishing information and gossip on tea. In the number for October 7th a very clearly printed map of India and Ceylon showing the position of the principal tea districts is given. A glance at this map shows by how large a portion of the Indian Empire, Ceylon and the Western Ghats, as scenes of tea culture in the south, are separated from Kangra in the extreme north, with Dohra Dun and Kumaon, forming a group yielding fine-flavoured but not luxuriant crops. These districts are again separated by a long stretch of the Himalayas from Darjeeling and the great homes of the plant, Assam and Sylhet. Between these north-eastern districts and Ceylon there is a long line of coast and an expanse of ocean, the coast line being broken only and close to Assam by the small tea district of Chittagong, while the insignificant group of estates in Chota Nagpore slightly lessens the long distance between Darjeeling and the Nilgiris. Over-production being a real danger already, it is well for tea growers that Burma has not, and is not likely for a prolonged period to have, labour in proportion to soil and climate suitable for tea, which is indigenous.—*Ed. T. A.*]

India and Ceylon are attracting so much attention that we present a map showing the tea-growing districts of Indian and Ceylon. The districts in which tea is grown in India at the present time are: Assam, Cachar, Sylhet, Darjeeling, Chittagong, Neilgherry hills, Chota Nagpore, Kangra, Kumaon, Sikhim, Nepal, Dehra.

It is claimed by Baildon, author of a work on tea, that India is the natural home of the tea plant. It is of exotic growth in Japan, where it was introduced, according to some authorities, in the 6th century, others placing it during the 9th century.

The Province of Assam, once called the Inferno of Bengal, owing to its humid and deadly climate, with jungle fevers, ague and tigers, holding supreme sway has been transformed into a fairly cultivated district. Parts of the province are reached by railway and the steamers of two lines. Hundreds of thousands of acres of open land are now to be seen planted with tea. This, it is claimed, has changed the character of the climate.

Mr. Ball says: "Recent discoveries in Assam also seem to justify the assumption, if nothing to the contrary be known, that it (tea) has spontaneously extended its growth along a continuous and almost uninterrupted mountainous range, but of moderate altitude, nearly from the great river, the Yang-tse-Kiang, to the countries flanking the South-western frontier of China, where this range falls in with or, agreeably with the opinion of a well-informed and scientific author, Dr. Royle, forms a continuation of the Himalayan range. But in those countries, as in every part of China, if found in the plains or in the vicinity of habitations and cultivated grounds, it may be fairly assumed that it was brought and propagated there by the agency and industry of man."

"In the early days of the tea enterprise in India indigenous plants were collected and formed into gardens, and China plants, propagated from seed, were planted in close proximity to the Indian species. The Chinese plants having entirely changed from what they were in their origin, in the botanical course of nature imparted their altered condition, in some degree, to other plants around them, and the very obvious result of planting two kinds of tea came about in the production of a third the hybrid. From the small proportion of China plant originally placed in the experimental gardens, we see the wonderful blending of nature in the fact that very little purely indigenous, or purely China tea remains, the various tea-producing districts in India almost all growing hybrid bushes. There are sections of a few—I was almost saying two or three—estates in Assam, where the indigenous plant is cultivated exclusively, and the greatest care is taken to keep all China and hybrid plants out of the way, so as to insure the continued purity of species."

The United States Minister to the United States of Colombia, Hon. John T. Abbott, states that competent authorities declare certain sections of the Republic to be peculiarly adapted for the development of tea culture.

[One of hundreds of such places where the absence of cheap labour places a ban on the culture.—Ed. T. A.]

GOVERNMENT CINCHONA PLANTATIONS.

[We received our own copies of the Madras reports, only after the following notice had been marked for extract.—Ed. T. A.]

It is now a little more than 30 years since the Government of Madras started cinchona planting on the Nilgiris, and the success which has attended its efforts to produce a febrifuge of excellent quality at a low cost—one of the main objects with which the plantations were opened—for sale to the natives have been rewarded with success. The practical effect, however, of the action of Government in selling quinine for almost the cost price will undoubtedly, as Government remarks in its Order on the Report of the working

of the plantations during last year, to a great extent be nullified if no local market is available for the medicine. "His Excellency in Council regards it as a matter of the highest importance that the medicinal value and the low cost of quinine should be widely known," and he rightly believes that "publicity is the chief thing wanted in order to obtain for it a ready sale." Notices are inserted in all the District *Gazettes* calling attention to the low price at which quinine is obtainable, and the Tahsildars, Postmasters, Revenue officials and heads of villages have been supplied with packets of quinine and asked to let the public know that the medicine can be obtained from them. Perhaps it is too early yet to give a definite opinion as to the general success or otherwise of this experiment; but quinine distributed in some Districts has not met with the ready sale that was anticipated, a fact which is attributable in great part to the apathy of the officers entrusted with its sale. The Government thinks it not natural that amongst the poorer classes, whose education is imperfect, there should be a rooted objection to any payment however small, for a foreign medicine of which the effects are comparatively unknown; but it is hoped that by patient and persistent efforts on the part of Government officers and by the gradual spread of the knowledge of the effects of quinine in preventing and curing fever, any existing scruples may be overcome. The general use of quinine amongst the people is undoubtedly a result most earnestly to be desired, but until the apathetic gentlemen are taken smartly to task little amelioration can be expected. Government, however, fully sees the necessity of the natives reaping the benefit of enjoying the advantages of a new remedy for a disease which prevails in one form or another almost everywhere throughout the country, and is productive of greater mortality than any other; and it at the same time does not forget the planters, who would profit by a rise in prices consequent on any large increase in the demand for bark—a hope earnestly expressed but unlikely to be fulfilled for some time. During the past year the imports of quinine into India rose from about 15,000 lb. to over 30,000 lb., a fact due, Mr. O'Connor assumes, to the retail druggists taking advantage of the rise in exchange to replenish their stocks at a profit to themselves. The unfortunate people who find themselves obliged to consume this drug not having obtained the benefit of the low price at which it is now placed wholesale on the market, there has been no large incentive to use it more freely.

During the past year the crop of bark harvested on the Nilgiris amounted to 133,351 lb. apportioned thus:—Dodabotta, Crown bark 63,342 lb; Naduvatum, Red bark, 51,230 lb and crown bark 3,530; Pykara, crown bark 10,166 lb and Red bark, 6,953 lb. At the close of the previous year 477,741 lb of the bark remained in stock in the godowns, which, added to the foregoing, brings the total bark in stock up to the huge figure of 611,695 lb. Of this only 100,400 lb were disposed of during the year, leaving therefore in stock at its close 510,695 lb! Only 2,928 lb of quinine were manufactured, against an estimate of 4,000 lb. The decrease was due, according to Mr. Lawson, the Government Botanist and Director of Cinchona Plantations, to the influenza epidemic in the early part of the year, which drove a number of old and experienced hands away, necessitating the employment of fresh hands; to an insufficiency of machinery; and to the tardy supply of chemicals necessary for the manufacture of the alkaloid. Upon these points the Government remarks that there was no severe outbreak of influenza at the factory; that the Administration Report is not the place for the discussion of the efficiency or otherwise of machinery; and that the tardy supply of chemicals was no doubt a serious obstacle to speedy and extensive work, but that for future Mr. Lawson should send in all incidents for submission to the Secretary of State at least six months before the articles are required. Of the sulphate of quinine manufactured, only 1,356 lb. were disposed of, of which 800 lb. went to Ceylon and 400 lb., to Bombay; 1,572 lb. thus remaining in stock at the commencement of this year. This and more, has already been indicated for, and the outturn

during the current year, therefore, in order to keep pace with the demand, should be at least 4,000 lb.; but Mr. Lawson has made no estimate. The price of the drug, it may be mentioned, has fallen from R16 7-9 to R14-11-3 per lb. 1,050 lb. of febrifuge were made during the year, and this, and 400 lb. in hand at the beginning of the year, has been issued in indents to the Medical Stores Department in Madras and Bombay.

Regarding the condition of the quinine sent to Ceylon, the Medical Superintendent of the Medical Stores, Colombo, said that its appearance was very much against it, and asked that future supplies might be better crystallised.* Unless this point was attended to, it could, he said, never compete with Howard and Sons, or other well-known, quinine. Mr. Lawson denies that the crystallisation was bad; in fact, he says it was really very good, the bad appearance of the quinine being due to its having been partially dried by pressure instead of by absorption, and that the crystals thus became broken up. On receipt of the Medical Superintendent's letter an offer was made to take all the quinine back and to send in its place an equal amount of hotter looking stuff, but the Superintendent said he would not do this, he only hoped that for the future a better looking sort of quinine would be sent. This seems to have been done, for since his remonstrance no further complaint on the matter has been received. The actual receipts of the Nilgiri plantations during last year amounted to R28,876, against a revised estimate of R40,000, but it credit be taken for the quinine and bark issued during the year, of which the value was not realised before its close, the receipts are raised to R30,529; and if the value of the stock in hand at the end of the year be also included at the rates prevailing during the year the figure comes to R73,555. The net result of the operations, taking the last figures, show that there was a debit balance at the end of the year of R4,832. Since the commencement of planting operations in 1860 there has been a deficit of 211 lakhs of rupees; the value of bark applied to the quolinologist for experimental purposes, and that of quinine and tephruge sold has amounted to a little over one lakh; the value of bark sent to England or supplied to other Governments or departments has amounted to close upon 32 lakhs of rupees, while the sales of plants, seeds, etc., has brought in a revenue of R75,381. The total expenditure during the past thirty years has been 35-86 lakhs, and the total receipts 33-75 lakhs.—*Madras Mail*.

SACRED TREES OF THE WORLD.

The Palm, the Oak and the Ash are the three trees which since times immemorial were held to be sacred trees. The first among them, which figures on the oldest monuments and pictures of the Egyptians and Assyrians, is the Date-palm (*Phoenix dactylifera*), which was the symbol of the world and of creation, and the fruit of which filled the faithful with divine strength and prepared them for the pleasures of immortality. "Honor," said Mohammed, "thy paternal aunt, the Date-palm, for in Paradise it was created out of the same dust of the ground." Another Mohammedan tradition of a later period says that when Adam left Paradise he was allowed to take with him three things—a Myrtle, because it was the most lovely and the most scented flower of the earth; a Wheat-ear, because it had most nourishment, and a Date, because it is the most glorious fruit of the earth. The date from Paradise was, in some marvellous way, brought to the Hejaz; from it have come all the Date-palms in the world and Allah destined it to be the food to all the true believers, who shall conquer every country where the Date-palm grows. The Jews and the Arabs, again, looked upon the same tree as a mystical allegory of human beings, for, like them, it dies when its head (the summit) is cut off, and when a limb (branch) is once

cut off it does not grow again. Those who know, can understand the mysterious language of the branches on days when there is no wind, when whispers of present and future events are communicated by the tree. Abraham of old, so the rabbis say, understood the language of the Palm. The Oak was always considered a "holy" tree by our own ancestors, and, above all, by the nations of the north of Europe. When Winifred of Devonshire (680-754 A. D.) went forth on his wanderings through Germany to preach the Gospel, one of his first actions was to cut down the giant Oak, in Saxony which was dedicated to Thor and worshipped by the people from far and near. But when he had nearly felled the Oak, and while the people were crying and threatening the saint, a supernatural storm swept over it, seized the summit, broke every branch, and dashed it, "quasi superni motus solatis," with a tremendous crash to the ground. The heathens acknowledged the marvel, and many of them were converted there and then. But the saint built a chapel of the wood of this very Oak and dedicated it to St. Peter.

The sacred Oaks, it must be admitted, do not seem to have always done their duty. Thus, for instance, a famous Oak in Ireland was dedicated to the Irish Saint Columban, one of the peculiarities of the tree being that whoever carried a piece of its wood in his mouth would never be haunted. After a time, however, the holy Oak of Kenmare was destroyed in a storm. Nobody dared gather the wood except a gardener, who tanned some shoe leather with the bark; but when he wore the shoes made of this leather for the first time he became a leper and was never cured. In the Abbey of Vevron, in Brittany, stood an old Oak-tree which had grown out of the staff of St. Martin, the first abbot of the monastery, and in the shade of which the princes of Brittany prayed whenever they went into the abbey. Nobody dared to pick even a leaf from this tree, and not even the birds dared to peck at it. Not so the Norman pirates, two of whom climbed the tree of St. Martin to cut wood for their bows. Both of them fell down and broke their necks. The Celts and Germans and Scandinavians, again, worshipped the Mountain Ash, and it is especially in the religious myths of the latter that the "Askor Yggdrasil" plays a prominent part. To them it was the holiest among trees, the "world tree" which, eternally young and dowy, represented heaven, earth and hell. According to the Edda, the Ash Yggdrasil was an evergreen tree. A specimen of it (says Adam of Bremen) grew at Upsala in front of the great temple, and another in Dithmarschen, carefully guarded by a railing, for it was, in a mystical way connected with the fate of the country.—*Deutsche Rundschau*.

NOTES ON PRODUCE AND FINANCE.

SIR ANDREW CLARK ON TEA.—It was Sir Andrew Clark who spoke against Indian tea the other day, and it was in the course of a lecture to the students of the London Hospital that he delivered himself of the opinion that Indian tea was especially bad for nerves. This is what he said:—"Tea is a blessed beverage. I do not know what I should do without it. But there is tea and tea; and one of the teas which I have in my mind is the representation of all that is physiologically wicked. I go about town a good deal, holding consultations here and there, and about five o'clock when I get into a place the lady of the house will say to me, 'Sir Andrew, you look so tired, do let me give you a cup of tea.' I say, 'Thank you very much.' But the tea has stood for half-an-hour; and she remarks, 'I know you do not like it strong, Sir Andrew,' and then she puts about a tablespoonful of tea into the cup, and fills it up with water. Now, I call it positively cruel to give tea like that to anybody, and I hope you gentlemen will always set your face against such a beverage. Tea to be useful should be, first of all, black China tea—the Indian tea which is being cultivated has become so powerful in its effect upon the nervous

* A specimen received by us from Dr. King, of quinine manufactured by Mr. Gammie, was as pure as Howard's.—*Ed. T. A.*

system that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of tea intoxication, and it produces a form of nerve disturbance which is most painful to witness. If you want to have, either for yourselves or for your patients, tea which will not injure and which will refresh, get black China tea, putting in the right measure—the old-fashioned teaspoonful for each person, and one for the blessed pot. Then pour on briskly boiling water, and within five minutes you must pour it off again, or it will become wicked instead of good. Let this patient, therefore, have half a pint of milk and water or cocoa, or half a pint of tea, *a la* Clark, if you please." Unfortunately for the value of this opinion, it is a well-known fact that medical men seldom agree upon any point, and their views upon tea are as divergent as upon alcohol. If Sir Andrew Clark prefers China tea he is welcome to his opinion, but when he tells the student of a London hospital that British-grown tea is deleterious, and advocates the use of China tea in preference—as though he had studied the question deeply and arrived at the conclusion after careful analysis and considerable research—he should support this advocacy with something stronger than a mere expression of opinion. To give expression in a public place to a statement unsupported by one jot of evidence is, to say the least, very unfair to the Indian tea industry. [Hear! Hear!—Ed. T. A.]

LAST WEEK'S TEA SALES.—The *Produce Markets' Review* says:—"The increased imports of Indian tea continue to supply the market liberally, the quantity offered at the public sales being upwards of 43,500 packages. Notwithstanding this heavy weight of tea, the demand was equal to it, and the market closes strong, with an advance in some cases strong, with an advance in some cases on the prices of the preceding week. The better quality of the teas generally accounts for the increasing activity in the demand. The growths which command most attention are those from the Assam districts, as these teas are, on the whole, superior to those of several seasons past, which is borne out by the comparatively high prices that have been paid. The quality of the Darjeeling teas is fairly satisfactory, but falls considerably short of the earlier arrivals, while those from the Sylhet and Doorga gardens, with few exceptions, continue to be inferior to the imports of the previous season. It is satisfactory to learn that strong representations have been made to those interested in the manufacture of the latter growths of the undesirability of continuing the newly-adopted method of preparing the leaf, which, it is hoped, will have the desired effect. At the public sales 43,376 packages were brought forward, and only 4,200 were withdrawn. The above quantity comprised a good selection of all grades, and from the quantity sold it will be seen the demand was well sustained. At the public sales very steady prices have been obtained for nearly all descriptions of Ceylon tea. There has been a good assortment of tea of fair quality, all of which has sold well. Fine to finest Brookes were actively competed for, and in several cases 1s 8d to 1s 9d was realised for fine descriptions. Fine Pekoes were in specially good demand and sold at rather better prices, while the lower grades of Sonchongs kept fully up to last week's rates. Of the 15,976 packages offered at auction 1,620 were withdrawn. In Java, 808 packages were offered at sale, all of which sold at steady prices.

THE ABBOTSLIGH TEA ESTATE COMPANY LIMITED.—This company has just been registered, with a capital of £25,000, in shares. Object to acquire tea or other plantations in Ceylon or elsewhere, and to carry on thereat the business of tea, coffee and cinchona planters and with a view thereto, to take over the estate in Ceylon called Montefiore, in the central province of the island of Ceylon, and the Abbotsligh Estate in the same province. The first subscribers (one share each) are:—O. B. Smith, 7 Grove End Road, N.W.; N. Rowsell, Abbotsligh, Hutton, Ceylon; C. Harrison, 67 Lincoln's Inn Fields; H. W. Matthews, 9 Coleford Road Wandsworth; F. Viller, 24 Killo Road, St. Catherine's Park; F. Farris, 49 Morley Avenue, Nool Park, Wood

Green; C. Anderson, 12 Brookfield Road, S. W. There shall not be less than three nor more than five directors; the first shall be O. B. Smith, 7, Grove End Road, N.W.; W. W. Simpson, Winkley, Whalley, Lancashire; N. Rowsell, Abbotsligh, Ceylon; and C. Harrison, 67, Lincoln's Inn Fields, W. C.; qualification three shares; remuneration: the directors shall only be paid their expenses of travelling in England to attend the meetings of the Board.

THE COFFEE MARKET.—Messrs. Wilson, Smithott, and Co. say: The recent rapid and severe fall has, as is natural, been followed by a reaction which at first imparted steadiness to the market, and this, attracting orders, caused better competition, resulting in a recovery of 2s on ordinary qualities and 3s to 5s on desirable and colony kinds. Supplies at sale during the fortnight were extremely small, arrivals being unimportant. The first new crop Jamaica was catalogued, and, being of inferior quality, sold at a low price. Central American kinds are very scarce; the Costa Rica crop is over for the season, fine qualities in second hands realise high prices privately, 10s 3d having been paid for good. Of Guatemala there is not much to attract buyers; dull and dingy old parcels sold at moderate prices, a few good with strong competition realised high prices. Good home-trade Vera Paz and Honduras continue to receive attention from buyers, the quality being very good. Brazil, after declining early in the fortnight, is in better request at the close, and an advance of fully 2s 1s established, recent advices pointing to some modification of the previous large estimate.

SPURIOUS COFFEE.—Coffee always was, and perhaps ever will be, one of the most abused articles of import and consumption; and as the scarcity of desirable qualities, for a long time past, has led to exceptionally advanced rates, the temptations to adulterate this homely beverage have been proportionately increased, says the *Grocer*. Adulteration, moreover, in America seems to be studied as a fine art; for the perfection to which it is brought there now is simply marvellous. We have before seen some fine specimens of sham coffee in its roasted state, but never have we examined anything so closely resembling the real article as that received by us this week from Philadelphia, which place is growing notorious for its swindling in coffee (so-called): Several respectable firms there, however, have taken upon themselves to expose these trade frauds, and are issuing circulars to warn the unwary against buying this "counterfeit" coffee. Deceiving as it may be in appearance to the ordinary observer, a practised eye can easily detect its false character, and avoid it accordingly; but when ground, ready for use the bogus coffee referred to is hard to distinguish from any other. Still, there are means of detection even then, which will show that it is not the product of the true coffee-bean grown in Ceylon, India, Central America, or the Brazils; and we may add that its liquor is of a dark colour, rather bitter in taste; with a thick, muddy sediment, and almost undrinkable. It is said to be of German manufacture—a sort of paste or farinaceous substance, first mixed with burnt oleary or some foreign colouring ingredient, moulded into the requisite size and shape by machinery—the same as pills and such-like medicinal preparations—and then the spurious compound is finally baked to give it hardness and consistency. In this form it is imported, and distributed largely in the United States, and, being sold at the low figure of eleven cents (or say 6d) per lb., or one-third the price of pure coffee, it naturally commands an extensive sale in the more populous districts where it is introduced. No honest trader can stand against mispractices of this nature, and it is hoped that the attention of the American Government will be drawn to the matter, with a view to protecting both their own revenue and the interests of the whole community.—*H. and C. Mail*, Oct. 30th.

THE QUANTITIES OF TEA that were sold to foreigners in Yokohama, and remained in stock in the city on the 15th inst. were 24,800 *kin* (one *kin* = 13 lb.) and 268,800 *kin* respectively.—*Japan Weekly Mail*, Oct. 17.

THE STANDARD TEA COMPANY (OF CEYLON), LIMITED.

A general meeting was held at the offices of the company, Tuesday October 27th. Directors present: Mr. Alexander Brooke (in the chair), Mr. Peter Moir and Mr. Robert Kay Shuttleworth. The chairman, said "the meeting was necessary with four months of registration of the company, under the Acts dealing with the incorporation of joint stock companies, in order that the necessary returns of capital might be made to the Registrar of Joint Stock Companies, which will be attended to by the secretary. The prospectus was issued with certain estimates of the probable produce to be expected from the St. Leonards estate during the year 1891. The estimates were Mr. Edward S. Grigson's. The company, as stated in the prospectus, was entitled to all the produce gathered from March 1st, i.e., entitled to the great bulk of the crops. I am happy to say that Mr. Edward Grigson, under date Colombo, Sept. 21st, reports that the quantities gathered since March 1st will exceed, in each case, the quantities estimated for the whole year, thus:—

	Original estimate for twelve months.	Revised estimate for ten months.
Coffee...	3,000 bushels.	3,500 bushels.
Cinchona	40,000 lb.	46,000 lb.
Tea Leaf	80,000 lb.	100,000 lb.

The expenditure will also be somewhat in excess of estimates, partly because they are estimates only, partly because of the increased quantity of produce to be cured and handled, for it goes without saying that the cost to transport and cure the greater quantity is more than the smaller—e.g., 3,800 bushels coffee more than for 3,000 bushels, &c. This produce has not yet come to any extent into the hands of the company. It is yet to be accounted for. The St. Leonards estate was handed over to the company on August 24th. Perhaps, if your directors had their own way, they would not have asked you to meet them until they had something more definite to announce, but the dates are settled for them; the Act requires the shareholders to meet within four months from the first formation of the company. All the capital asked for in the prospectus was applied for, and a good deal more. Many of the applicants for shares—I think I may say, the greater number—were residents in Ceylon, or people acquainted with the island and with the district of Udappussellawa, and some of them with the estate itself and its exact condition, and no perhaps hotter than anyone else in the island what are the prospects of coffee continuing to yield on a remunerative scale, and when the young tea mentioned in the prospectus will be in a playing condition, and thought favourably of those prospects. On tea, when it has attained full bearing is our chief reliance. The production of tea is greatly on the increase both in India and Ceylon; but Ceylon holds its own wherever it has obtained a footing. It has maintained it, because it is a good article, and no one accustomed to it will go back to an inferior article such as China, notwithstanding anything Sir Andrew Clark may have said. The best Ceylon teas promise in the opinion of your directors most permanency in this respect. Among the best of the Ceylon teas are those from Udappussellawa, and your directors have pleasure to announce that they have arranged with Mr. Norman W. Grieve, the owner of Eskdale and Liddesdale Estates, near to the company's property, St. Leonards to throw in his lot with the company from January 1st 1892. I prefer to say Mr. Grieve throws in his lot with the company, to using the expression "that the company have contracted to buy from him and for this reason, that Mr. Grieve takes a great part of the purchase-money in shares of the company, and your directors hope to have him as a valued colleague. The election of a director is strictly a matter in the hands of the other side of the table; but Mr. Grieve is a well-known man in Ceylon, is a gentleman of high character, knows the districts, has had experience as a planter and

CAMPHOR FROM JAFFNA.—This article of export is used in the manufacture of smokeless powder, and came into prominent notice when this invention was first publicly announced. The stock at that time in London was exceptionally small, so that values were suddenly forced up. In order to maintain the abnormally high level of prices produced by speculation, dealers withheld supplies for many months, bringing to market only sufficient to meet actual engagements. The bulk of shipments to Europe were so well watered that the loss in weight upon arrival there was found to be in many instances from 17 per cent to 20 per cent., instead of the usual $7\frac{1}{2}$ per cent to 10 per cent. Prices at one time during the year rose nearly 100 per cent but closed quite normally.—*Manufacturer and Inventor.*

TEA PREPARING MACHINERY.—Here is an item that may interest tea-men. We take it from the *Kokkai*:—"Tea is among the most important articles of export from this country. Every year about 60 million lb. are sent abroad. Hitherto in the manufacturing districts everything has been managed by hand, the expense being great and the profits to producers small. In India on the contrary machinery is used with the result of materially economizing time and outlay. Lately the Governor of Saitama Prefecture informed the department of Agriculture and Commerce that a certain Mr. Takebayashi Kouzo of Kawagoye, in that Prefecture had invented a tea-preparing machine after many years of labour and experiment. The Governor asked that an expert be sent by the Department to examine the machine. This duty was entrusted to Mr. Omura Takeshi and he has reported that he found the invention thoroughly suitable and very convenient. He added that if the machine be brought into general use throughout the tea-producing districts, a great saving of time and expense will be achieved."—*Japan Weekly Mail, Oct. 24th.*

ARTIFICIAL IVORY.—Persistent attempts have been made to produce a good artificial substitute for ivory, says the *Engineer*. Hitherto none has been successful. A patent has recently been taken out for a process based upon the employment of those materials of which ivory is composed, i.e., tribasic phosphate of lime, calcium carbonate, magnesia, alumina, gelatine and albumen. By this process quicklime is first treated with sufficient water to convert it into the hydrate, but before it has become completely hydrated or "slaked," an aqueous solution of phosphoric acid is poured on to it, and while stirring the mixture the calcium carbonate, magnesia and alumina are incorporated in small quantities at a time; lastly, the gelatine and albumen, dissolved in water, are added. The point to aim at is to obtain a compost sufficiently plastic and as intimately mixed as possible. It is then set aside to allow the phosphoric acid to complete its action upon the chalk. The following day the mixture, while still plastic, is pressed into the desired form in moulds and dried in a current of air at a temperature of about 150° C. To complete the preparation of the artificial product by this process, it is kept for three or four weeks, during which time it becomes perfectly hard. The following are the proportions for the mixture, which can be colored by the addition of suitable substance: Quicklime, 100 parts; water, 300 parts; phosphoric acid solution, 1.05 sp. gr., 75 parts; calcium carbonate, 16 parts; magnesia, 1 to 2 parts; alumina, precipitated, 5 parts; gelatine,

MANA-GRASS EXPERIMENTS AND THE COMPLAINTS REGARDING CEYLON TEA CHESTS.

LONDON, Oct. 30.

We have heard nothing very recently about what is to be done respecting the mana-grass tea chests. We presume that those concerned are yet awaiting the result to their reference to Ceylon. But Mr. Rogivue, in his letter asks very particularly as to the chances of his being supplied with such tea chests. He writes that those wooden ones in which he receives his consignments of Ceylon tea are very bad, and that they do not bear the long railway journeys. In his opinion "it would be a great thing if they could be replaced by better ones." He would evidently be well pleased if he could receive his tea in stronger and more durable chests. We can readily understand that this would be so, for the distances to be travelled by railway in Russia are so enormous that the weak boxes which are now received from Ceylon cannot be well calculated to stand the shaking and rough handling they are certain to receive. It might be as well, should your estate superintendents know that they are packing teas to be forwarded to Mr. Rogivue if they would give a little extra strength to the boxes. Mr. Elwood May, we know, makes similar complaints as to your tea chests, and that he intends repacking all the tea he distributes throughout the States in highly finished boxes of local manufacture. These complaints are not only well founded, but they should act as a stimulus and encouragement to those who are now working the Stanley-Wrightson Syndicate in conjunction with the mana-grass experiments.

I forgot, when quoting Mr. Rogivue's letter, to tell you that the principal points of discouragement mentioned in it have been communicated to Messrs. Travers & Sons of 119 Cannon Street, and that that firm propose to give them publicity in the *Produce Markets Review*. A letter from the firm shown to me evidences that they think it questionable if China tea can be further displaced here to admit of a profitable market being found in Great Britain for the large, annually-increasing production of Indian and Ceylon tea, and that they are therefore fully alive to the necessity that exists for you to open up new markets abroad.—London Cor.

CROPS IN SOUTH INDIA.

SEASON TELEGRAM TO THE GOVERNMENT OF INDIA, REVENUE AND AGRICULTURAL DEPARTMENT, CALCUTTA.

Week ending 7th November. Rainfall continued heavy to Madura and Tinnevely; fair and moderate in all other southern and western districts, northern parts Ganjam and at three stations in Vizagapatam; elsewhere in five northern coast districts and in Cuddapah, Kurnool and Bellary little or none. Anantapur light rain tolerably general. Weather on 8th, Bellary, promising. Some improvement Ganjam and Anantapur, but more rain urgently required there and in uplands of Kistna, Nellore, Kurnool, Bellary Cuddapah, where crops withering and cultivation greatly retarded. Pasture and water-supply improving in all southern districts, but dry fodder scarce. In Bellary, Anantapur and Kurnool pasture and fodder scarce and cattle suffering, but in general want of water. Previous high prices continue generally, though fallen slight in Chingleput, South Arcot, Tanjore, Trichinopoly, Tinnevely and on West Coast and risen slightly Madura Cuddapah, Vizagapatam, Ganjam; sharp rise Kurnool, Bellary and Anantapur. Works—numbers employed—Chingleput 5,626, Wandiwash 918, Polur 1,694, Kalahasti 2,779, Cuddapah 551, Coimbatore 4,233 and Salem 3,854, total 19,665, against 22,303 last week.

Kitchens—numbers fed—Obingleput, 1,443, including 831 children; Wandiwash 655, including 383 children; Polur 132, including 100 children; Kalahasti 1,519, including 1,120 children; Coimbatore 856 and Salem 24, including 116 children; total 4,869; decrease from last week 673. Loans disbursed from commencement of distress—Chingleput R3,70,146, Wandiwash and Polur 1,52,069, Ouddapah, Nellore, Coimbatore, Tinnevely, South Arcot and Salem 1,81,045. Wells constructed—Obingleput 1,409, Wandiwash and Polur 209, and six other districts 216. Wells under construction—Chingleput 2,465, Wandiwash and Polur 1,257, and, six other districts 998.

SOUTH AFRICAN DIAMOND MINING.

The production of the diamond mines of Griqualand West, South Africa, has been steadily declining during the past three years. This does not, however, appear to be due to any falling off in the supply of the precious stones, but rather to the measures taken for the restriction of production by the larger companies which have recently absorbed many of the smaller undertakings. The great object of the consolidation of a number of small companies and subsequent restriction of output was to increase the price of diamonds, and it seems from the statistics of diamond mining in South Africa that this step has been so far successful. The amount and value of the output of these mines in 1890 has not yet been officially returned. For the three years preceding the statistics are as follows:—

MINE	1887—Production		1888—Production		1889—Production	
	Carats	Value £	Carats	Value £	Carats	Value £
Kimberley.....	1,383,832	1,410,298	1,632,869	1,270,873	816,135	1,132,440
De Beers.....	1,022,878	1,403,406	585,414	347,105	1,012,572
Dutoitspan.....	356,124	568,013	158,464	490,886	547,850
Bultfontein.....	612,246	659,887	612,763	541,304	746,311
River diggings.....	45,665	31,950	61,031	29,492	75,485
* Total.....	4,125,039	3,597,095	3,668,873	2,784,459	4,165,000

* In addition, the St. Augustine mine which, was worked intermittently, produced during the three years 427 carats valued at £602. The Otto's Kopje mine produced during the same time 665 carats valued at £661.

The Kimberley mine, which is now practically in the hands of the Central Diamond Mining Company, had been opened in 1877 to a depth of 740 ft.; in 1883 it was sunk to 825 ft., and in 1889 to 845 ft.; no further depth is reported in 1890. In 1887 the De Beers mine was down 700 ft., and in 1883 805 ft. A great development of the underground system took place in 1889. This mine is owned by the De Beers Consolidated Mines Company, which in 1889 also secured control of the Bultfontein property, which had attained a depth of 460 ft. at the close of 1887, and 620 ft.

at the close of 1888. The St. Augustine mine has been worked to comparatively small extent. At the close of 1888 the main shaft had been carried to a depth of 450 ft., and in 1890 it was sunk 75 ft. further. The Otto's Kojjo mine had reached a depth of 800 ft. in 1889.

The average value of the diamonds raised at the Kimberley mine in 1880 was \$6.74 per carat; in 1887 the average value was but \$1.893. Similarly, at the De Beers mine the average value increased from \$4.983 per carat in 1887 to \$6.73 in 1889. At the Dutoitspan mine there was an advance from \$6.88 per carat in 1887 to \$9.43 in 1889; at the Bultfontein mine from \$4.94 to \$6.703; at the St. Angustino from \$6.16 to \$8.12; at the Otto's Dopje from \$4.51 in 1888 to \$7.32, and at the river diggings and mines from \$9.93 in 1887 to \$12.99 in 1889. It will be observed that the most valuable diamonds are raised from the river diggings.

The number of persons employed in the diamond mines of Griqualand West in 1890 is officially returned as 7,249, as compared with 8,102 in 1889, and 11,453 in 1888. The number of lives lost last year was 33 as compared with 105 in 1889 and 303 in 1888. The large number of fatal accidents reported is attributed to insubordination among native miners, their disregard of orders involving a heavy proportion of the loss of life which has occurred during the last three years. The wages paid to white miners in the Kimberley and De Beers mine range from \$17.50 to \$34 per week; Kafirs received \$7.80 per week, with food, water, lodgings and medical attendance. In the Dutoitspan and Bultfontein mines, wages are somewhat lower.—*Engineering and Mining Journal.*

GOVERNMENT QUININE.

Sir Charles Elliot's remarks on Brigade Surgeon G. King's report of the Cinchona Plantations and Factory in British Sikkim for the year 1890-91 are worthy of the attention of District Officers and all Civil Surgeons. It is twenty-nine years ago since the Bengal Government entered upon this cinchona enterprise, not with a view to profit, but with the avowed intention to reduce the price of quinine which then stood at a practically prohibitive rate, to one rupee per ounce. The plantation and factory have met all expectations, and not only does the price now stand at the latter rate, but the net profits for the year under notice amounted to seventeen thousand rupees. It is truly remarked that "hardly any greater blessing to a fever-stricken country can be imagined than cheap quinine;" and with respect to the Sikkim product, we have ample assurance that cheap quinine does not mean inferior quinine. Government quinine, Dr. King assures us, has been shown by repeated analysis to be of the highest possible purity, which he goes on to remark, "is a good deal more than can be said of much of the foreign quinine that is sold in Calcutta," and he might have added, "elsewhere in India." But this is not all. There is in stock a large amount of raw material and of manufacturing product, proving that the producing capacity of the plantation and factory is greater than the demand for the product; and it would be possible still further to reduce the price of quinine if more charitable dispensaries were to supply themselves with the Government drug instead of buying elsewhere at prices from 12 to 25 cents* higher. The Lieutenant Governor of Bengal is drawing the attention of the Inspector-General of Civil Hospitals of that Province to the matter, and it would be as well if a similar course were adopted in the Punjab. The necessity of having a plentiful supply of real, genuine quinine ready at hand for distribution in the Punjab is not so urgent this year as it was last; but it cannot be too prominently brought home to the responsible authorities where such an article can be obtained in quantities; it would cripple the finances of no Municipality or District Board to purchase liberally. In cases of unusual and sudden outbreaks of fever, purchases are

apt to be made in the nearest market, irrespective of price, and on such occasions dealers are tempted to adulterate an already inferior antiperiodic to meet such requisitions and to make a good thing of the m. This could easily be guarded against by laying in a reasonable stock of pure and cheap Government quinine, and it is somewhat surprising that this has not been insisted upon long ago. The Punjab Government has made spasmodic attempts to induce district officers to distribute the drug liberally, but, like all such attempts, they do not last long. When the capacities of the Sikkim plantations become better known, we are confident that quinine, cheaper even than a rupee an ounce, will be obtainable in abundance in India.—*Civil and Military Gazette.*

THE TEA TRADE continues, and some demand exists for better grades than those in request for some weeks past. Settlements of leaf to date are 235,000 piculs against 208,000 same time last year, and exports foot up 27½ million pounds against 23½ millions at the same date last year.—*Japan Weekly Mail*, Oct. 17(b).

GERMAN enterprise in New Guinea is increasing. With the object of establishing plantations in the territory of the New Guinea Company, for the cultivation chiefly of tobacco, a company, to be known as "The Astrolabe Company," has just been formed in Berlin with a capital of 120,000*l.* Experts are of opinion that parts of New Guinea are admirably suited for the growth of the tobacco leaf, and, of course, any quantity can be absorbed in the manufacture of German cigars, which, by the way are being exported in larger quantities than ever to this country.—*E. Mail.*

MR. WYNDHAM, the British Consul at Paramaribo, the capital of Dutch Guiana, in a report just issued by the Foreign Office, refers to gold mining in that colony and says that the industry is steadily increasing, and with the introduction of capital will be a great business. A slight decline in production has occurred during the last two years, but this is to be attributed largely to placer owners building their hopes on companies and syndicates buying their land, and, in the meantime, ceasing the developments necessary to keep up the average returns. The auriferous belt extends throughout the three Guianas from Cayenne to Venezuela in an easterly and westerly direction, in width about 100 miles. The formation of the gold belt is metamorphic, slates, schists, and occasional dikes of sandstone and gneiss. Mining has been principally confined to alluvial washings, and very satisfactory results have been so far obtained. The amount of gold exported increased from 475,953 grammes in 1879 to 1,029,777 grammes in 1888. Last year the export amounted to 987,218 grammes. The Government has done nothing to open up the country by the construction of roads, or making the river more navigable for small steamers to advance the mining interests of the colony. Private enterprises have had to rely upon their own resources in this respect. It is only during the past two years that any attention has been given to quartz mining, and the developments during this time have produced highly satisfactory results. After describing the work done on various mining properties, the Consul adds that there is a good field there for capitalists, and when the reefs now discovered have been developed and suitable machinery erected, the results cannot fail to be satisfactory. The ore is free milling, and wood and water are abundant for all mining purposes, consequently the cost of working will be nominal. All machinery for manufacturing and mining purposes is admitted free of duty.—*London Times.*

* Per cent?—*Ed. T. A.*

OUR BUILDING MATERIALS AND THE GOVERNMENT.

Not long back we devoted considerable space to a series of articles dealing with the different forms of material used in this colony for building operations. We therein pointed out how much might be done to improve their natural qualities, or the manufacture of such items as have to be prepared for use. We are glad to realize that our Government has seen the desirability of affording help towards carrying out the second of those suggestions, and that an experienced man from home is to be put in charge of an endeavour in that direction. This is not the first time that our rulers have recognised the desirability of affording some aid towards the improvement of our building materials. It is now fully thirty-five years back that brickmaking machines were obtained from England and distributed throughout our several provinces. We never heard, however, that any success was achieved by these. Perhaps they were in advance of the necessities of the time and that their possible output was too largely in excess of requirements to enable them to be profitably worked. But it is further possible—as we know that at that time large makers of bricks in England preferred hand labour to the use of these machines—that they were nothing like so well adapted to their purpose as those made in the present day. At all events, whatever the cause may have been, no appreciable results appear to have followed from the attempt we have alluded to. The second endeavour made to introduce improved building material was we believe somewhere about 1861, when Mr. Giles was sent out from home to join the Public Works Department, he having previously undergone a training at home in the manufacture of artificial stone from silicious materials easily obtainable in the colony. We think this artificial stone was named after its inventor, Mr. Ransome. Although a very considerable expense was gone to with the object of producing a material the use of which might relieve the then monotonous appearance of our public buildings, Mr. Giles's attempts appear to have failed of success, from what cause we do not now remember. The only stone of a permanent nature to be obtained in Ceylon is granitic gneiss, with occasionally pure granite; and the cost of working these rocks for ornamental purposes is almost prohibitory. If Mr. Giles had been successful, undoubtedly we should have seen pleasing results; but, as we presume, disgusted with the failure of the first two efforts made, our Government appears never again to have departed from its beaten track, although it obtained from England an architect to whom improved material easily worked would have been an invaluable aid. We think it very likely that a mistake was made in the endeavour to introduce a new material instead of devoting the money that endeavour cost to an attempt to improve existing local methods of manufacturing building material. It was with such a view in our mind that we wrote the series of articles dealing with such matters as the making of bricks, tiles, &c., and recommending that endeavour should be made at improvement. It is in this latter direction that our Government is now moving, and we may hope ere very long to see some beneficial result from its action in this direction. The services of an expert in any special branch of material need not be very long retained, and when he has trained native pupils sufficient to disseminate his teaching, an expert in some other branch might profitably be engaged. By such a method we are sure sooner or later to obtain improvements which

as we pointed out in our previous articles referred to, are so desirable if our buildings are to be works of permanence and not to be possessed but of a brief life only. Matters such as we have indicated will come well within the legitimate scope of the Technical Institute about to be established.

THE EFFECT OF MANURING ON TEA.

The following letter was, as will be seen, circulated for the opinions of experienced planters, but so few have responded that we suppose most are in the position in which Mr. W. F. Laurie acknowledges himself to be, unable to speak from experience on the point at issue. Here is the letter and our foot-note:—

(Circular from "Observer.")

A planter has addressed the following letter to the Editor, whose own opinion is adverse to the idea that the application of fertilizing matter could deteriorate the quality of tea. But he naturally desires the opinions of the leaders of the planting community on the subject, and will feel much obliged if favoured with the result of your experience and observation at your earliest convenience. Oct. 15th, 1891.

(Letter referred to.)

October 12th.

DEAR SIR,—I would feel obliged if you or some of your numerous correspondents would give me their opinion on the effects that Poonac and Bones have on the quality of tea. I am a novice myself and I would not bother you, but still I have had a little experience, and my opinion is that artificial manure does not improve the quality. I know an estate that has been all manured within the last 3 years with castor cake and bones, C. C. $\frac{3}{4}$, B. $\frac{1}{2}$, about half a ton to the acre, and the said estate previous to manuring always topped the market. Now for the last eighteen months the prices have tumbled down at least 3d per lb; what is the reason? I know for a fact that the tea has always been treated in the same way for the last five years, so there is a something; is the manure drawing some dormant chemical matter out of the soil which is affecting the tea? Now, Mr. Editor, you as a party directly interested in our welfare should do your best to find this out. I could give you a list of estates that have been manuring heavily the last 2 years, and now instead of their prices being above the Ceylon average, as they used to be, they can't now get within a penny of the average. My own experience is that the yield is enormous but there is in my opinion a taste in the tea that should not be there. I could enlarge on the subject if I were not a

NOVICE.

(The results of an extensive experiment on a Chittagong estate, a few years ago, were not only increased quantity, but improved quality, price being the criterion of the latter.—Ed. T. A.]

Mr. W. F. Laurie's response runs thus:—

October 22nd.

Sir,—I am not in a position to say whether the manuring of tea results in the tea produced lacking flavour or not, although I should think it possible. It would not, I presume, be owing to the manure drawing some chemical property from the soil, as "Novice" implies; at least, if the result be deleterious to the produce, it would in all probability arise from the habit plants have of absorbing a small proportion of highly solvent material from the ingredients of the soil, unnecessary for their healthy existence or general economy, such as has been indisputably proved by water culture and do not wholly change in the elaboration of the sap.

In the analysis of healthy plants, many of the peculiar properties of the land upon which they are grown have been discovered in them.

Certain manures too have been found quite unsuited for delicate vegetables, through imparting to them a decidedly disagreeable flavor.

On many of the famous vine-farms of Europe, manuring has resulted in entirely destroying the special bouquet of the wines made upon them.

On the other hand, many plants grown for the specially delicate aroma of their produce have improved upon manuring, such as melons, peaches and many other luscious fruits, although I should think as a general rule the delicacy of the aroma and flavor would be impaired.

Upon the tea I have mostly to deal with, manuring has so far not been found necessary to such a degree as to enable me to form any opinion on the subject, but I shall now have teas made from manured parts separately, to see if I can discover any distinctive character about them.

Manure would, I should think, have a much more direct influence upon the immature leaf in this respect, such as make the finest teas, than upon matured fruit, coffee for instance; for the ingredients of the plant food and what accidentally may accompany it in the form of sap, would be in a less elaborated condition than in the mature leaves that have more fully thrown off volatile matter with their gases and moisture.

Another ascertained fact is the mere general existence of delicacy of flavor from plants grown in inferior rather than rich soil, an instance of which we have in our own cinnamon that has, I believe, never been beaten; and this rule applies to many other plants.

However my opinion is chiefly by analogy and upon general principles, to which tea may be an exception, yet I should think there might be an unfavorable effect produced in this respect by the application of manure especially upon the finer grades.

I regret that time will not allow me to write more upon so interesting a subject, so fully experimented upon by scientific cultivation which would I think be against the application of most of the usual fertilizing materials by those who desire to produce fine flavored teas. If quantity alone were sought my opinion would be different.

WM. FORBES LAURIE.

Another planter writes as follows:—

Referring to "Novice's" letter about quality of tea and artificial manuring—I am unable to give you anything approaching proof for or against his theory. My opinion is at present an undecided one. I have manured here with artificial manure a small acreage during the last three years, of which however I was absent from the island fully 18 months. Since my return I have been so busy that the question has not had as much attention as it deserves. I cannot say, however, that I have noticed any deterioration in quality of tea from manured fields as compared with unmanured fields, and on the other hand I cannot say I have noticed any improvement. I know however that Mr. Joseph Fraser used to think his tea from manured fields slightly better in quality. I leave entirely out of the question all consideration of quantity. The question is an interesting one, but facts and not opinions are what is wanted.

Our inferior teas are always made during the season of rapid growth—whether due to this rapid growth or to bad climatic conditions for manufacture or to want of accommodation, &c.—that is a fact. Manure (artificial) certainly produces a more rapid growth also, which is at least something in favour of "Novice's" theory; but I think the theory is contrary to the received ideas of almost all manuring.

The dose of ester cake and bones mentioned by your correspondent gives a very large dose indeed of phosphoric acid or soluble phosphate of lime per acre—far larger than there seems any necessity for, and is very much after the principles laid down by Hughes for coffee, which is quite another matter. I should be very curious to know what the yield of tea manured with this mixture was, before application and in the two succeeding years (with dates of pruning). Curiously enough, "Novice" himself answered our circular, and in very decided terms, thus:—

In answer to your circular letter above "Novice" manuring tea with artificial manure. My experi-

ence is that the yield is increased for 2 years by one-third on good tea and on poor tea doubled, but. I am now convinced the quality is not so good. Liquor from manured tea is poor this stuff and wanting in flavour; this is my opinion after careful experiments from leaf of the same field $\frac{1}{2}$ manured $\frac{1}{2}$ not manured. It is for men in position to settle the question, not a man with the experience of "Novice."

Besides the Chitlagong experiment to which we have referred, there is the experience of Mr. Joseph Fraser, entirely in favour of manuring both as regards quantity and quality. It is quite possible that in the case quoted by "Novice" over-manuring resulted in a rank growth, and that improvement in flavour would take place subsequently. But the experience in China seems conclusive in favour of manuring. The Chinese collect and apply as manure every possible fertilizing matter, even the grossest, and yet the distinguishing merit of China tea has always been its delicate flavour! Indeed a China paper quoted by us in our issue of Nov. 11th distinctly attributes the recent falling off in the quality of teas brought to Foochow, to neglect of manuring. The terms of this impeachment are:—"These latter folk [the growers,] go on plucking tea from worn out plants, growing in exhausted soil which is never renovated by manure of any kind. How is any better tea to be obtained under these circumstances?" In China, therefore, the belief seems to be in the absolutely beneficial effect of manure and the absolute necessity of manuring for the production of tea of good quality. There may be questions as to the kinds and the quantities of manure to be applied to tea, but the conclusions of "Novice" carried to their extreme consequences would place tea in a category different to that of all other cultivated plants, necessitating its culture after a fashion which would inevitably result in the utter exhaustion of the constantly plucked bushes and the soil in which they grow, without an attempt being made to restore the waste, except at the risk of ruining the quality of the product. Who is prepared to accept such a *reductio ad absurdum*? In the vast mass of literature connected with the tea enterprise in India which we have read, we cannot recollect that such a question as the deleterious effect of manuring was ever raised, nor can we bring ourselves to accept the conclusion that manures judiciously selected and moderately applied, can be other than beneficial as regards quality as well as quantity of leaf. Surely there are estates even in so young a tea country as Ceylon where experience has settled the question of the influence of fertilizers on flavour.

ROADS IN AMERICA, GREAT BRITAIN, AND FRANCE.

The common roads and country highways of the United States are in a condition at present somewhat similar to that which prevailed in England and other parts of Europe one hundred and fifty years ago. Some of the ancients were great road-builders, notably the Romans and Carthaginians. Remains of the great Roman roads are still to be seen in Italy, and in many instances these old highways are either still in use or furnish the foundations for the modern roads. With the decadence of the Roman power road building and maintenance suffered with everything else, and the great highways which radiated from the capital city were left to the care of the various neighbourhoods through which they passed. They suffered the severest neglect, but such was the solidity of their construction that some of them have remained till

now, and the remains exhibit a method of building which for thoroughness has never since been equalled. The location of these roads was not skillfully made, for they usually went in straight lines from one landmark to another, regardless of the hills or valleys intervening. This method of location very frequently involved grades none necessarily steep, but those old road-builders did understand thoroughly the two great principles without which no good road can be made—drainage and solidity. The administrative method was also a direct one from a central power, and therefore there was system in planning and building and maintenance. And it may be remarked that there are no good systems of roads in any part of the world at this time where this work is left to the various local authorities.

The movement for better roads in England began in 1770. Up to that time, from the days of the caravans, when merchandise was carried from place to place on the backs of beasts of burden, the roads in England had always been bad, but their condition did not entail widespread suffering until the population became dense and there was an actual necessity for an interchange of products and commodities from neighbourhood to neighbourhood. Macaulay tells us that previous to the era of improved roads in England "the fruits of the earth were sometimes suffered to rot in one place, while a few miles distant the supply fell short of the demand." And further on he points out the reason. "One chief cause of the badness of the roads was the defective state of the law. Every parish was bound to repair the roads which passed through it, and thus a sparse and impoverished rural population was often compelled to maintain highways between rich and populous towns." England met this difficulty by the establishment of a comprehensive system of turnpikes, and before the beginning of this century thirty thousand miles of these had been built. There are no traces of Roman roads in England, therefore these turnpikes were not fashioned after that model. Instead, they were built very much in the same way as that which generally prevails in this country. A line was located, or the old highway line adopted, and stone piled on the surface and left for the wheels of passing waggons to pack into a solid mass. Little or no attention was paid to drainage, and therefore the new turnpikes were not a great improvement on the old roads. It was not until the time of those two great road-builders, Telford and Macadam, that anything like good common roads were built in Great Britain. And with the era of better roads, the names of those two men will always be associated in those parts of the world affected by English influence. They have shown us how to build roads at a very much less cost than the old Roman way, and they answer modern purposes quite as well.

The name of Telford is associated with a pitched foundation which is always desirable for a road subject to very heavy traffic. It consists of flat stones carefully set on edge in course across the road, with the broadest edge downward. The upper edges should not exceed four inches in breadth, to hold the broken stone well. All irregularities must be knocked off and small stones and chips must be firmly pinned into the interstices with a hammer, so as to form a regular convex surface, with every stone firmly fixed in place. The thickness of the pitching is generally six or seven inches; it should not be less than four, and it may generally be thicker without any sensible increase of cost. At least four inches of broken stone are required over the pitched foundation, and when consolidated six inches are always suffi-

cient. But before laying this pitched foundation Telford insisted that the road-way should be thoroughly drained, so that there would never be any considerable dampness below the metal pavements. Macadam, the other great scientific road-builder, differed from Telford as to the necessity for such heavy foundations. He maintained that the dry subsoil, however bad, would carry any weight that could be placed upon it if it were made dry by drainage and kept dry by an impervious covering of stone well bonded together. The Macadam pavement, therefore, as originally designed, consisted only in perfectly draining the subsoil of a roadway, covering it with broken stone to a thickness of from six to twelve inches, and rolling this until it had become packed and bonded together. Where the traffic is very heavy the Telford pavement is unquestionably the better of the two; but the Macadam pavement would most admirably answer the purpose for nine out of every ten miles of roadway in America. In this country we are in the habit of speaking of any road as macadamised which has a simple covering of broken stone. It is rarely, however, that the subsoil of such roads has been drained at all. Without the drainage the stone might as well be spared, as the dirt road would be quite as good. After the advent of these great road-builders in England—they flourished in the first half of this century—there was a sensible and marked improvement of the highways in both England and Scotland, until now the roads which were once almost impassable, and were a serious burden to the people owing to the great cost of transportation, have been made hard and smooth, and a horse can draw for a given distance a load three times as heavy as on the roads of the olden time. In addition to this, what was once a serious undertaking—that is, a journey by coach from one part of England to another—is now a pleasure much indulged in by tourists and other travellers who care for a closer intimacy with the country than can be had from the windows of a flying train. Even in the Highlands of Scotland the roads are so well built and maintained that one can drive all through that mountainous region without finding a mile of road as rough as our ordinary city streets.

But France has a system of roads far superior to that of Great Britain. The great Napoleon appears to have been the first modern statesman and soldier in Europe who appreciated from a military and economic standpoint the vast importance of good highways and at the same time had the power to carry out whatever plans he wished. He organised and started the method of road building and maintenance which has ever since been observed in France, which now has the best roads of any country in the world, and what is quite as much to the point—at a less cost than that which is paid elsewhere for highways much inferior. They have a special department of the Government, of which the Minister of Public Works is President, devoted to roads and bridges. This department maintains a college for the education of the engineers who are to be employed by it. There is always a staff of about six hundred engineers and inspectors on duty. The roads of the Republic are divided into several classes—national, departmental, military, and vicinal. The national roads are twenty-five thousand miles in total length, and are built and maintained entirely by the national treasury. The vicinal or cross roads are built and maintained chiefly by the communes, but under a national administration. On these roads there are constantly employed fifty thousand workmen and three thousand overseers. On the national roads the work is planned, and inspected directly by the officials of the department. On the vicinal

ros' the parts are submitted to the public, and the work during its progress a subject to the constant inspection of the national engineers. There is, therefore, no chance for any haphazard work even where local money is expended in making and repairing roads. The thriftiness of the French people has long excited the admiration of the world. Neither internal revolution nor defeat from abroad has entailed upon this people burdens too heavy for them to bear. The splendid roadways which unite commune with commune and villages with village have helped them no little in their struggles against adversity, for the tax which by poor interior communications is put upon the business of a country has been reduced in their case to the very lowest point. And how much have these roads to do with the contentment to be found among the rural people of France! The French agricultural classes are singular among the farmers of the world in not holding that all the world is at war with them. It is true that they practice better methods of farming, but it is the good roads which to a great extent enable them to do this, for they can get their products, however perishable, cheaply and quickly to market.

—*Lippincott's Magazine.*

POINTS AND TECHNICAL TERMS IN POULTRY.

The points and technical terms used in poultry phraseology are given in a recent number of the *Cultivator and Country Gentleman of Albany, New York*, by S. B.:

- 1—Comb, of which there are five forms, single, pea or triple, rose, leaf and fork.
- 2—Face, the fleshy matter around the eye, usually red, but white in Spanish, and purple in Silkie.
- 3—Wattles, pendulous fleshy appendages just below the beak. Always red except in Silkies. Varies greatly in length, and does so in accordance with the size of the comb.
- 4—Ear-lobe, or deaf-ear, pendant ornament on the face, just below the rear ear. Red in some breeds, white in others, and also yellow and purple.
- 5—Whiskers, only found on a few breeds, and those almost entirely crested varieties.
- 6—Crest, top knot of feathers, in some varieties very much developed, notably Polish, Crevecoeur, Sultans, etc.
- 7—Beak, horny substance at mouth, varying in color from white to yellow, principally the latter.
- 8—Beard, (see No. 5).
- 9—Neck-hackle, the flying feathers on the neck, very profuse in some varieties.
- 10—Breast, usually bold and prominent, less so in the Asiatic breeds than in others; varies greatly in color.
- 11—Keel or breast bone, must be straight, and the deeper the better is the fowl for the table purposes.
- 12—Back very long in some breeds and as short in others.
- 13—Saddle, the feathers hanging below are called the saddle hackle.
- 14—Thighs, or fleshy part of the leg.
- 15—Hocks, always covered with feathers, but in some breeds stiff feathers protrude therefrom, and are called hock feathers.
- 16—Spur, specially prominent in the cock, and more so in some breeds than others. Increases in size year by year.
- 17—Fifth-toe, found on some birds, notably the Dorking and the Houdan.
- 18—Beak-claw.
- 19—Muffs, or leg feathers. In most of the heavier Asiatic breeds of poultry, feathers grow down the side of the leg, and on the outer part of the foot. In Cochins, Brahmans, Sultans, etc., these are highly developed.
- 20—Shoulders, very prominent in a few breeds, notably Malays and the Game varieties.

- 21—Tail-fluff.
 - 22—Centre-toe.
 - 23—Shank, or leg.
 - 24—Wing-bar, the band or cross-marking on many fowls.
 - 25—Primary coverts, the outer feather of the wing.
 - 26—Primary flights, not seen when the wing is in repose.
 - 27—Sickle feathers, the long sickle feathers which form the outer sweep of the tail, and are such a graceful addition to that important part of the fowl's plumage.
 - 28—Primary tail, the shorter, straighter feathers of the tail, and in some varieties the principal.
 - 29—Secondary sickle, like the outer sickle, but smaller.
 - 30—Tail coverts, the falling feathers, or hangers, below the base of the tail.
- Rural Californian.*

THE TASMANIAN SILVER-FIELD.

The first discovery of Tasmania was made on November 24th, 1642, by the Dutch navigator Ablo Jans Tasman. The first land sighted by him was the mountain subsequently called Zeehan, after one of his ships, and the hills and coast line in its immediate vicinity. This mountain and the surrounding district, owing to the denseness of vegetation and the unfruitful appearance of the soil, remained a *terra incognita* from the period of its discovery until some five or six years ago, when the hardy colonial prospector, in his restless search for gold penetrated its dark and inhospitable forests, and discovered, not the looked-for yellow metal, but the white. Little was thought of this discovery at the time. The colonists recognized the fact that silver was there in the Zeehan country; the prospector went his way searching for gold or tin; and so the matter remained in abeyance. But the great success of the Broken Hill mines taught the Tasmanians duly to appreciate the possible wealth of Zeehan, and within the last few years the quest for silver has been pursued with energy. One discovery of silver deposits has followed another, and altogether 80,000 acres are rented from the Government, on renewable 21-year leases, for silver-mining purposes; and in the centre of what is believed to be the richest portion of the field, one of those mining towns which rise as by magic about the shaft and poppet heads is rapidly assuming the proportions of a city. Two years ago the site of the present town of Zeehan was a valley of myrtle, blue-gum, and pine trees, with here and there a few calico tents twinkling through the foliage. Now it is a cleared space, upon which some 3,000 people have settled either in houses of their own or in large and well-appointed hotels, that provide accommodation for hundreds. Four churches have been erected or are in course of erection; public halls and billiard saloons furnish amusement for the residents; a bright little tri-weekly newspaper keeps the miners *au courant* with the affairs of the outside world; and the carpenter's saw and hammer are heard day and night, making further provision for the crowds which continue to pour in from the districts of Tasmania and the neighbouring colonies. It is estimated that about 6,000 people are now upon the field, the majority of whom are actively employed in mining, and every succeeding day brings its own evidence of the rich abundance of silver ore which is a waiting development.

During the past two years nearly 200 companies have been placed upon the Melbourne, Hobart, and Launceston markets, and the shares have been readily subscribed for, chiefly by capitalists who have during the past few years gleaned a rich harvest in the silver-field of Broken Hill. Most of the companies are now actively engaged in developing their properties, and many are putting out large quantities of payable ore. Although nearly all silver-mining necessaries, such as timber, water, and smelting fluxes,

are obtainable on or close to the field, the mines, so far, have been working under serious disadvantages in regard to communication with the port. Owing to the heavy rainfall of the district (nearly 100 inches per annum) and the spongy character of the soil, it has been found impossible to make roads capable of bearing heavy loads of mining machinery and ore. The Government of Tasmania, recognizing this fact and also the vast importance of the field, are constructing a line of railway to connect Zeehan with the nearest suitable seaport—Straban, Macquarie Harbour. This line, which is 29 miles in length, was commenced in January, 1890, and is now so near completion that before the end of the year it will be possible to convey, at comparatively slight cost, mining machinery, smelting furnaces, hoisting material, &c., from the port to the field, and (pending the erection of local smelting works) the ore, now lying at the mouths of the mines, from the field to the port, where it may be shipped to the smelters at Adelaide or Sydney.

With two exceptions, the mining companies have stacked their ore on the field, preferring to await the completion of the railway to taxing their ore to the extent of £7 to £8 per ton, the cost of road carriage. It is satisfactory, however, to know that in the case of one of these (the Silver Queen Company), the company have been enabled to declare regular monthly dividends of 2s on their 12s shares, in the face of heavy transit expenses (the loss being equal to 1½ oz. of gold per ton).

This company's ore, when smelted yielded an average of 95½ oz. silver and 4 cwt. lead per ton, and the other company referred to (the English Mount Zeehan Silver Mining Company) have made a very handsome profit out of some 500 tons of ore which have been shipped to England from their mine, and yielded over 100 oz. of silver per ton.

The silver-bearing country extends from Mount Zeehan northward to the Picman river, and eastward to Mount Dundas and Mount Murchison. Explorations to the northward of the Picman river have recently resulted in the discovery of further silver-bearing land, which extends to Henzlowood, then eastward to the Whyte river, and westward to the Savage river. By following out these discoveries on the map it will be seen how widely the silver deposits are distributed, and when it is remembered that the great extension of the fields has taken place during the last two years, and that the country, covered as it is with dense scrub is most difficult to prospect, it is clear that what has yet been found can only be regarded as indicating the great mineral wealth to be brought to light in the course of time.*

The silver ores found on the west coast are without exception smelting ores, being associated with so much lead that no other treatment can deal with them as advantageously as smelting. Native silver has been found freely associated with galena. Chloride of silver is found in the mines near Mount Zeehan, generally in the oxidized upper portion of the lodes, with oxide carbonate, and phosphate of lead as associates.

The main quantity of silver is, however, not to be found as definite visible compounds of the metal, but impregnated invisibly as sulphide through galena. This mineral is found throughout the Zeehan fields, of great purity and high silver value, assays of it ranging between 30oz. and 250oz. of silver to the ton.

Large quantities of ore fit for immediate smelting, with no other previous treatment than rough hand-sorting in the mine, can be readily obtained, and the more impure ore is easy of concentration. The oxidized ores of lead, carbonate, sulphate, oxide, and phosphate, found sometimes in large quantities, may all be easily smelted. They are generally much richer in silver than the galena. With them kaolin, rich in

* And yet, with such prospects, a man in America talks of artificially preserving the purity of silver to gold. The proportion is now 22 oz. of silver to 1 of gold, instead of the old rate of 15 to 1; and we suspect the downward process, in the case of silver, has not yet ceased. Ed. T. A.

silver but poor in lead, has been found in considerable quantities in the Silver Queen Mine.

Highly argentiferous fahl ore (tetrahedrite) has also been obtained, though somewhat sparingly.

The country rock is of the Silurian age, and the lodes in which the ores occur are of the true fissure type, and have every indication of permanency and depth. For instance, the banded structure, so characteristic of many lead lodes in Europe that have been proved to a great depth is, frequently seen at Zeehan. Some of the lodes have been systematically traced for over two miles, and it is believed that some of them extend a greater length than this, although, owing to the dense scrub, tracing on the surface is difficult.

The fine fissure lode, locally known as the King Lode, has been cut at various distances extending over two miles, on the Silver King, the Silver Bell, the Silver Crown, and Dispatch Mines. A tunnel, 6 ft. by 4 ft. and cut 500 ft. in length, has yielded ore valued at over £30,000 on the Silver Bell property.

In a recent report on the Tasmanian silver-field Mr. Montgomery, the Tasmanian Government Geologist, says:—

"Taking everything into consideration, the proximity of the seaboard, the railway communication shortly to be completed, the large number and general richness of the already proved lodes, the presence of suitable fluxes for smelting, the water power available, the abundance of mining timber, and the great extent of country which may be relied upon to produce ore, it may be regarded as a certainty that the silver-fields of the west coast of Tasmania will support a large population for many years and an extensive and remunerative mining and metallurgical industry.

There seems to be sound foundation for this belief, and the Tasmanian silver-field should materially augment the local wealth and the value of that colony's exports.—London Times.

"A VISIT TO AMSTERDAM."

INSPECTION OF A DIAMOND-CUTTING ESTABLISHMENT.

I felt greatly indebted to Mr. de Busay for securing me the privilege of going over the largest diamond-cutting factory in the city, my immediate predecessor in this inspection being the Princes of Naples. Amsterdam is noted as the principal seat of the diamond-cutting industry, and the numerous factories with the large number of employes make it quite an important matter for the Dutch capital that the diamond fields in South Africa and Brazil, if not in other parts, should continue in abundance. Indeed, the past year has been a trying one to a large proportion of the Jewish population who form nearly all the diamond-cutters, through a great falling-off in the receipt of the precious stones from South Africa.* We found, however, no lack of business and activity in the large house we visited. The first cause of surprise was at the size of the building, the many spacious rooms and the extent to which machinery was required. It seemed at first glance as if we were entering some cloth or metal factory, rather than one in which such small, though precious, items as "diamonds" were manipulated. The building was, as might be expected, a thoroughly strong, substantial one, iron being used freely in the construction for the stairs, beams and even flooring in some parts. Precautions against fire are no doubt indispensable. On the basement, apart from necessary entrance offices, we found the steam-engine and boiler room-power being transmitted up three or four stories by belting. We began our formal inspection, however, at the top of the house, where

* The effect of Mr. Cecil Rhodes's policy.—Ed. T. A.

in a compact comfortable room we found some half-dozen experts dealing with diamonds "in the rough." They had a most ingenious way of holding the gem in wax fitted into a handy tool, while with a diamond cutter in the other hand they proceeded to test and seek out any flaw. Diamonds were lying about in what seemed to us rather a careless way; but apart from visitors allowed in, being very few and far between, and always under responsible guidance, the operators are, through a system of co-operation more like partners, while for all diamonds handed to them, they are made strictly responsible, the record being taken not simply in number but by weight each morning before commencing work. A flaw having been detected in a stone, it is the business of the operator to cut it out in the most scientific manner consistent with the utilising of the gem otherwise. This done, the diamonds are passed down to the next floor where more skilled workmen are employed cutting round the now flawless gem and making it ready for polishing: they are assisted by lathes driven by the steam machinery at the basement. The third and most important treatment is the polishing, and here we have a large room full of machinery, drums, pulleys and belts flying around at great speed to give the requisite speed for the polishing of the many facets of the diamond with diamond dust. But it may be asked how are the gems, so small as most of them are, held by the polisher or the machine in which the polishing takes place. Wax is obviously too soft for this operation, and so it has been found that lead is best, each polisher having a man behind him melting lead and inserting the diamond in a large lump which, when cool, shows only the one facet of the diamond that has to be operated on in polishing. So that for each facet, there must be a fresh melting and re-arrangement, and when I state that there are 64 facets in all (32 on each side) of a stone, it will be judged that even with the aid of machinery and all modern appliances, two days are not too much for the polishing of a single diamond. But then in the polishing machine, revolving nearly 1,000 times a minute, several stones are being operated on at once. I happened to have with me a Ceylon catseye, small but of good shape and colour, and a "Metara diamond" (which, by the way, had been pronounced by a Dublin jeweller some years ago, to be glass) and the young experts dealing with diamonds in the rough, were a good deal interested in the Ceylon stones—to them novel and interesting, especially the catseye. The "Metara diamond," they tested and pronounced to be "a diamond of the second-class." We were shown the difference between the Brazilian rose diamond and the white stone of the South African finds. Then by permission of the heads of the house, we were taken to see some of their special property in the safe—a splendid collection of finished, sparkling gems, set and unset. Finally we inspected models in glass of all the great diamonds of the world, including the "Great Mogul" belonging to the Tsar, cut as a rose and not very clear; of the "Kohinar" as originally got for Queen Victoria and as afterwards cut, a brilliant of the first water and magnificent in size; the diamond worn in his cap by the Shah of Persia; some of the very fine diamonds in the French State collection; a grand stone found at the Cape; and I suppose among the models must have been one of the diamond sent by Mr. Jacob of Simla to the Nizam, valued at £430,000, which has lately been the subject of a trial, the Nizam repudiating the bargain and returning the stone. Altogether, a most interesting afternoon was spent in this, the largest Amsterdam

Diamond-polishing Establishment, making us for the future to understand and appreciate the great care and exactitude manifested in this branch of industry.

JAVA TEA AND CACAO AND SUMATRA TOBACCO.

There is one matter I want to bring before the Ceylon Planters' Association in reference to Java planters and Holland. While Amsterdam is decidedly the headquarters market for Sumatra tobacco (and very depressed I found this market to be, scarcely any dividends for shareholders and owners this year), and Java cinchona bark; yet the same can by no means be said of Java tea and cacao. For the latter products Java planters look to London as their principal market, and thereby bring their crops into direct competition with those from Ceylon, India, &c. No fault can be found with them for this practice, *except insofar as they fail to cultivate and endeavour to create and extend a market in their mother land.* Already for "cocoa" there is a big demand in Holland, and "Van Houten's Cocoa" (we saw his Village Factory outside Amsterdam) being known far and near on the Continent, I cannot see why every cwt. of Java cocoa should not sell as advantageously in Amsterdam as in London. The case is different in respect of tea; for although in one province of Holland—Friesland, bordering on Germany—the people are reported to be great tea drinkers, in the country generally, tea-drinking is far from common and the product is only now beginning to come to the front, and I believe China rather than Java, teas rule the market. At any rate, I only saw one "Java Tea Agency" established in Amsterdam, and it is quite clear from the quantity (yearly increasing) of Java tea going to London, that the home market is not much cultivated or studied. Now, *why should not the Java tea planters be asked to do in Holland, what their Ceylon and Indian brethren have so well done in the United Kingdom?* Who but the Java planters in their Associations or Unions should make known the virtues of their teas to all the people in Holland and even Belgium and Western Germany, and "advertise, advertise" until not only is all "China" stuff driven out, but a vastly increased consumption of tea is established throughout the land. The effect of this would, of course, be to relieve the London market of Java tea, bringing it on to Amsterdam, and to increase the total Continental demand for our staple. Now, I trust the Chairman and Committee of the Ceylon Planters' Association or Tea Fund, will see that here is a case in which they may very well offer some good advice to the Java sister-institutions, based on their own example and experience. Surely the Java tea planters—a most enterprising body—will not refuse to organize and contribute to a fund to help to spread the fame of their tea in Holland and adjacent provinces; but in order to get them to make a start, the necessary impulse and information must surely be given from Ceylon. I feel sure it will not be Mr. Philip's fault if this is not done.

Amsterdam has a very full library and I spent a pleasant morning there, taking notes among the rest of, what seemed to me, all the uncommon volumes or State Records referring in any way to Ceylon, of which there was a goodly collection.—The grand Central Railway station is another feature of the Dutch capital—the building and very convenient as well as complete arrangements of this one sufficient station reflecting great credit on the authorities and architect, the building, testefully decorated, being a work of art in itself,

Correspondence.

To the Editor.

INDIAN AND CEYLON TEA FALSELY AND SLANDEROUSLY LIBELLED.

Crosshill, Glasgow, Oct. 28.

DEAR MR. EDITOR,—I enclose an advertisement which appears in nearly all the papers here, and which, I think, is very injurious to the island of Ceylon.

Perhaps it will be of interest to you.—Respectfully yours,
JOHN DOUGLAS.

"I DO LIKE THAT CHAP DI-SRAEL, HE IS A CLEVER CHAP, HE DO ALWAYS THINK AS I THINK,"

The above eulogium by a worthy Israelite and follower of the Earl of Beaconsfield, containing such a naive self-convincing reason, would, if slightly altered, aptly describe our attitude toward Dr. Sir Andrew Clark on the question of "Indian and Ceylon Tea versus China Tea."

In effect, this eminent physician confirms from his professional experience what we have been advocating for a Quarter of a Century—viz., "That China Tea (black, not green) is the only variety that may be drank with safety and refreshment."

And what Sir Andrew Clark refers to in general terms we substantiate by scientific data—to wit, the analysis of Twenty-four Teas at all prices, and fairly representative of the three leading varieties.

Price for price China Tea yields nearly as much Theino as either Indian or Ceylon, and is therefore quite as refreshing; but both Indian and Ceylon yield more than double, and in many cases treble, the amount of Tannin as compared with China Tea. Therefore, both Indian and Ceylon are most pernicious to the human system—and yet it is upon this basis that their claim to be considered Economical rests! Economy falsely so-called! The practice of borsewies of pouring a second supply of hot water upon the already opened-out leaves extracts the Tannin to the very dregs, and under this almost universal practice we believe that Indian and Ceylon yield from four to five times more Tannin than China similarly treated.

Little wonder that Sir Andrew Clark describes this as "the representation of all that is physiologically wicked!"

We believe that those bitter, pungent Indian and Ceylon Teas do more injury than would result from the same money's worth of the rankest raw-grained Whisky consumed within an equal period and at equal intervals; while China Tea would have no trace of bitterness, and would not offend the most sensitive palate or constitution.

One Rule will guide the Public—i. e., Buy no Tea which yields a black, bitter, or pungent liquor when infused at the ordinary drinking strength.

Many of the Blends which have the largest sale are entirely made up from Indian and Ceylon, and ought to be avoided by anyone who wishes to escape from that condition so graphically described by a physician whose motive it is to conserve the Public health.

"Tea to be useful should be, first of all, Black China Tea—the Indian (and also Ceylon) Tea which is being cultivated has become so powerful in its effects upon the nervous system that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of Tea-intoxication and produces a form of nerve disturbance, which is most painful to witness." "If you want to have a Tea which will not injure and which will refresh, get Black China Tea."—Extract from London Correspondence, *Glasgow Herald*, 16th October 1891.

We offer three choice lots of Pure Black China Tea, guaranteed to be mild and refreshing and free from bitterness, but of excellent flavour.

At 1/6, 2/6, and 2/9 per lb.

STUART CRANSTON & Co.,
Trained Tea-Tasters of over 25 Years' Experience.

MR. HENRY WALKER ON BRITISH NORTH BORNEO.

Kandy, Nov. 9th.

DEAR SIR,—Mr. Henry Walker, the Commissioner of Lands, British North Borneo, promised to send you a short sketch of what he found going on when he returned to North Borneo and of the prospects there. He has asked me to place at your disposal a copy of a letter addressed to a gentleman here who has kindly allowed me to publish the same.—Yours faithfully,

W. D. GIBBON.

Sandakan, Oct. 19th.

Dear Sir,—Mr. Gibbon sent me a copy of your letter of the 8th Aug. and I have purposely delayed replying until I had revisited the places where coffee has been planted—and I now write you after fully convincing myself that coffee is thriving better than I ever saw it do in Ceylon. I allude to Liberian.

Liberian coffee has only been planted near the sea and no plantation of any product has yet been done in the interior except on the big rivers and then only below launch limit. Our chief facility lies in the fact that transfer is cheap i. e. if prospectors can find land near to the principal stations.

At Kudat Silam and Sandakan there are trees of over five years, and Kudat about 25 acres of very nice coffee about five years old planted by Mr. Obriatian now in the hands of a Chinaman—and evidently paying. This is about 2 miles out and the land between the estate and the sea is rapidly being planted by the Chinese who have coffee growing about 300 yards from high water mark—looking well. The oldest coffee is some 4 miles out and was planted under my instruction in 1883. I could not visit this last, but I believe it is doing very well.

At Silam the 6 acres in the Government garden is still kept up, and both the Silam and Kudat coffee have no disease, while that at Sandakan has. The Sandakan soil is poor, but the coffee is thriving wonderfully—it has been abandoned since 1885 or 1886 and stands in a certain cattle run—and is healthy and bearing well. The trees are about 12 or 14 feet high, bushy and strong.

On the Kinabatangan river, Melapi Estate, Layanjan Estate, Darvel Bay, I saw splendid Liberian coffee in bearing and under two years old. Also cocoa on the latter estate. The cocoa at Silam (Orarons) has finer trees than anything at Pallekelly as regards stem, but is not so spreading as some I saw on Mr. Charles Gibbon's estate. The Silam trees are bearing heavily, and began to bear at the fourth year. Cocoa is cultivated by all the headmen—that is one or two trees—and it seems to do well.

The labor question, I do not think, will be difficult of settlement. We are opening (a private company) a coffee estate in Marudu Bay near to a Tobacco estate so that we have the advantage of established communication, shops, doctor, use of Lanch &c. and I believe from the little beginning made that we shall have no more difficulty than the Mas. keliya men had, if so much. Of course as the pioneer company we have had difficulties—for instance the Government promised a nursery of 200,000 plants and I find there are not 10,000 available for the monsoon's planting, but I expect in May and June we shall complete the first 100 acres. Anyone coming after us will be able to use our nurseries and the manager will be glad to increase them and charge ten rupees, or five dollars a thousand as we did in Ceylon.

The expenditure on 200 acres I estimate at \$9,590 for the 1st year and 38% for the 2nd year which includes \$2,400 and \$2,000 for superintendence, but not including cost of land which is \$3 per acre for other products than Tobacco, or for new products a special free grant of 1,500 acres may be made in the terms of the notification No. 49 of 1891 copy herewith.

I enclose a printed estimate and I consider it a fairly average one.

Very good land is to be had in Maruda Bay, or near Darvel Bay, and I have seen lately some land that is really splendid, but I should like you to come and see for yourself feeling sure as I do that you will say it is worth a trial.

Our market for coffee may be America, if so we are within easy reach of Vancouver, or if England then Holt's line will quote through rates. If I can give you any further information I shall be happy to do so.

Our seasons are much the same as in Ceylon.—Yours faithfully,

(Signed) HENRY WALKER,
Commissioner of Lands.

MR. WM. MACKENZIE AND THE TEA KIOSK.

Thornfield, Nov. 12th.

DEAR SIR,—In your leader in paper of 10th occurs the following sentence: "We have never been able to understand Mr. Mackenzie's special crusade against the kiosk at Colombo."

I don't know about the 'special crusade,' but I long ago stated my objection to be that Colombo was not the place to catch Americans and Russians, and proposed instead a kiosk near the Pyramids in Egypt. Our tourists are almost all Australians or people going to China or Calcutta.

We have already our fair share of the Australian tea trade, and can have as much more if we land good teas in Melbourne or Sydney at 6d to 8d. But Australian dealers will not pay London prices, as I and many others know by bitter experience. China and Calcutta grow their own teas.

But I had said my 'say' about the kiosk and was done with it. What I said about its connection with the New Company was in reply to a request from your 'junior' to give him my opinion. That also was, as you say, an "accomplished fact," and further that of ceasing to be a subscriber to the Tea Fund, I had 'moved on' as regards that matter also. Any controversy since has not been of my raising; and as my withdrawing of a letter by wire last week after you had it in type, proves I am content to let bygone be such!

We have all enough before us at present in preparing for adequate representation at Chicago. It is time space was applied for, and this cannot well be done, until we know what money we shall have to spend. If we do not aim high, we shall hit low. Besides the contributions from Government and Tea Fund, which will amount to about £6,000, I think we should raise £14,000, or £20,000 in all. What a trifle it seems to be contributed by 1,200 estates, nearly half of which have so far paid nothing to the Fund! Why, it is very much less than one month's wedding contract! But to approach this amount, regular owner to owner canvassing must be attempted. It will never be done by circular solicitations from the Tea Fund. That importunate lady has tried her charming too often in vain.

WM. MACKENZIE.

THE TEA KIOSK AND THE CHICAGO FAIR SUBSCRIPTION.

Nov. 16th.

DEAR SIR,—This building, now nearly completed, stands almost opposite the G. O. H. in Colombo, and long before the same was erected, it was considered that such an imposing spectacle would be certain to attract the flock of passing strangers, who spend a few hours on shore from the various steamers calling at our port. To see the building as it now is, one can hardly come to any other conclusion than that the whole idea has resulted in a miserable failure. A large sum of money

has been spent in the construction, and on the pillars which are made from a particular kind of wood; and now that the building is erected it does not look to me as if it would have any attraction for passengers whatsoever. That an insignificant little building such as the Kiosk is should attract even a tenth part of the passers-by from steamers seems to me most improbable, for the large hotel opposite looks for more enticing, and strangers are certain to patronise the hotel in preference to the Kiosk even for a good cup of tea.

Had the Kiosk been erected and carried on in Paris or New York or Sydney or even Port Said the results might have been favorable, but the position now seems as advantageous as a spot in Timbuctoo would have been. New York I should certainly have considered a more favorable location for its erection. It would have been in the midst—more or less—of a tea-drinking people. It would have been the means of bringing good Ceylon tea to the notice of many Americans, and the American Tea Company would have received benefit from advertisement. Whereas now the money seems well nigh wasted. I only hope it may be of service, and everything should be done to make it so. I have not been a subscriber to the Tea Fund, but I intend to give my donation towards the representation of Ceylon at the Chicago Exhibition together with an extra allowance of £100. We should now do all in our power to have Ceylon tea well represented there, for it will not only be the means of introducing our teas to numbers of Americans, but to thousands of strangers from other countries as well, and this chance of pushing our teas should commend itself to all planters and traders interested and supported as much as possible, seeing how badly we require fresh markets to take off our ever increasing supplies.—Yours faithfully,

W. A. T.

THE CHICAGO EXHIBITION.

DEAR SIR,—The subscription list started by the Chairman of the Chamber of Commerce has now been travelling round the Port for five days, but out of some fifty and more firms only four have appended their names as subscribers. The reason is not far to seek. The questions on most people's lips are: Who is to be the Commissioner? Is Mr. Elwood May to handle any more Ceylon coin? I venture to say that if these two queries are satisfactorily answered Mr. Bois will not appeal in vain, and that many of the community will at once add their names and materially increase the amount already promised. Why not call a public meeting to discuss the matter? Everyone admits the great importance of Ceylon being well represented at the World's Exhibition, but what is wanted is more light on the subject. The Banks and Steamer Agencies should come down handsomely, and so will most of the other firms, including my own, when satisfied as to who is to carry the price of £10,000, and spend it in America.

One of Mr. Elwood May's bright ideas was to boom tea by getting American newspaper proprietors to take scrip in his Company in payment of advertisements. This no doubt has been comparatively an easy matter owing to his trading under the auspices of the Ceylon Planters' Association and several local "Honorable." Now, however, newspaper proprietors are beginning to feel a desire to realize their scrip. Finding no market in their own country, they naturally turn to Ceylon. When they find scrip may be bought here at a discount of 75 to 90 per cent we shall no doubt be abused right and left in characteristic plain American language, and what

then about our tea? Will they continue to oulogise it? The answer is apparent to us all.

I mention the foregoing circumstances in order to show that the tactics employed by Mr. May will materially increase the difficulties of our Commissioners. They will have to conciliate numbers of irate newspaper shareholders, and possibly buy up some portion of the valueless scrip held by them in order to obtain notices in the leading journals. To have to do all this, and at same time look after the general interests of the island, will tax the energies of the most hard working man amongst us. Fortunately, however, we have identified with Ceylon a dozen or more men from whom to select Commissioners, acceptable to all sections of our community. The sooner they are selected the better. They will have to be heavily laden with rupees, and each man amongst us must put his hand in his pocket for the general good of the island. —Yours faithfully, A MERCANTILE MAN.

P.S.—The National Association count amongst their members a large number of men interested in trade with and products that go to America. Perhaps they are waiting for a public meeting to be held, before taking any steps in the matter.

[Any excuse for not subscribing, apparently, is eluded at: the Kiosk, the tea companies and Mr. Elwood May! Our view is that Government should choose one Commissioner and the Planters' Association another; the latter to have special charge of tea and estate products. As there are so many good men available, let us get plenty of money and then the best man can be selected. —En. T. A.]

ABNORMAL TEA LEAVES, two united even more closely than were the Siamese twins, are pretty common. Not so triplets, a specimen of which has been sent to us. Such eccentricities are not confined to tea, but are common to many forms of vegetation. The *Gardener's Chronicle* recently figured a leaf streaked with brilliant colours, which had made a desperate effort, largely successful to become a flower. It is almost inconceivable that the most formidable thorn and the loveliest blossom are but modifications of the same principle.

CINCHONA COMBINATION RUMOURS.—The *Chemist and Druggist* of 31st Oct. says:—The projected Java quinine factory still continues to agitate the cinchona interest in Java and in Holland. Mr. H. I. Prins has his say on the subject in the last issue of the *Indische Mercator* to the extent of two columns; but his contribution cannot be said to throw much additional light upon the question. Mr. Prins ascribes the failure of the old Milan quinine factory to the conclusion of the well-known agreement between the Soekawana and Djajagiri plantations and the Brunswick quinine works, which he says was signed in 1886. He does not explain how it is that the Milan factory failed about two years before that agreement was heard of. He calculates that the only serious item in the establishment of a quinine works in Java is the cost of the machinery. Wages, coal, chemicals, and petroleum are very cheap, and there will be an enormous saving in bark freight and sale expenses in Europe. The freight from Java to Holland is about 71s. per ton; sale expenses are also heavy, the total charges between the port of shipment in Java and the delivery to the buyer in Holland being about 20s. 3d. per bale. Mr. Berkhout, an old resident in Java, also devotes a lengthy article to the question, and succeeds in broaching one or two new ideas. He admits that quinine has found a very serious opponent in antipyrin, the large consumption of which he ascribes partly to the free manner in which it has been advertised. Arguing upon these premises, he advises the planters to combine for the purpose of making known by advertisements that quinine is now obtainable at very low prices, a fact

of which the public, he thinks, are still ignorant. Mr. Berkhout estimates that a quinine factory in Java would have an advantage over European makers of a saving in cost of 1d per oz. of sulphate of quinine. On the other hand, the cost of making sulphate of quinine would be much heavier in Java than in Europe. Mr. Berkhout estimates, from an inspection of the books of a German factory, that the production of one kilo. of quinine in Europe costs 1s 10d in chemicals, and requires 1½ cwt. of coal. The total cost of manufacturing quinine in a German factory in the years 1890-91, according to its published balance-sheet, was a fraction over 2d. per lb. He recommends the formation of a syndicate composed of brokers, manufacturers and planters, and disposing of a capital of say, 25,000l., which would buy up all bark for which manufacturers were not willing to bid 1d. per unit at auction.

LABELS ON INDIAN AND CEYLON TEA.—We attract attention to a letter from Glasgow with reference to an offensive advertisement by dealers in China tea. It is only natural that the Glasgow dealers should desire to preserve the "craft" by which they have so long profited; and had they contented themselves with exalting the mild merits of China black tea (which, however, the tea-drinking public are appreciating less year by year) their advertisement might be allowed to pass. But their virulent libels on the superior teas of India and Ceylon are, we regret to believe, knowingly false; for Messrs. Stuart, Cranston & Co. describe themselves as tea tasters of 25 years' experience. As such they must know that medium Indian and Ceylon pekoes, obtained at moderate prices, are equal to the very finest high priced pekoes which China produced in her best days, and that the statement that Indian and Ceylon teas yield four or five times as much tannin as China is absolutely untrue. There is in the Indian and Ceylon teas just a sufficiently larger percentage of tannin to constitute their superiority to China. If China tea is so treated that all the tannin is extracted from it, the brew will be neither a pleasant nor a wholesome beverage; and no person who knows how to infuse tea properly will leave the boiling water more than five to seven minutes over the leaves. The proportion of tannin in such an infusion of the strongest Indian and Ceylon tea is not injurious but beneficial, the very rash and discreditable utterances of Sir Andrew Clark to the contrary notwithstanding. The abusive language applied to Indian and Ceylon tea, by interested persons, like Stuart Cranston & Co., and the dishonest person who was prosecuted for selling China tea under the name of Ceylon, reminds us of the insane ravings of a firm of brokers called Sellar & Co., who, in the days when Indian tea was first making itself felt in the English market, were only less demoted in denouncing the new product than in condemning the sin of lending out money at interest! Our readers will be amused at the warning of the Glasgow dealers in China tea, against blends, because they are composed chiefly of Indian and Ceylon tea! The public know their own interests, and the beneficial effect of good tea properly made, too well to be affected by the ill-advised utterances of medical eccentrics, or the selfish and false libels of dealers like the Glasgow men; and in spite of medical crank and mercantile partizans, Indian and (especially) Ceylon tea will increase in favour and in consumption, to the benefit even more of consumers than producers, although we trust with ever a fair profit to the latter.

* One of them obtained notoriety, which was no doubt his object, by denouncing that valuable substance Liebig's extract of beef as being merely a stimulant, similar to alcohol.

AREA UNDER TEA IN INDIA AND CEYLON AND PRESENT APPROXIMATE CROPS.

The figures for India are embodied in the following:—

Memo. of the Approximate Area of Land under Tea Cultivation in the following Districts in India in 1891:—

	Area in Acres.		
	Mature Plants.	Immature Plants.	Total Planted Area.
Assam	112,708	18,542	131,250
Cachar	50,472	6,000	56,562
Sylhet	37,448	5,748	43,196
Darjeeling	35,978	5,993	41,971
Terai and Dooars ..	23,658	5,399	29,057
Chittagong	3,876	187	4,063
Chota Nagpore .. .	3,280	607	3,887
Dehra Doon & Kumaon—			
Kangra Valley ..	8,680	518	9,198
Madras	10,868	—	10,868
	286,968	43,084	330,052

Of 330,000 acres under tea in India, it will be seen that little more than 10,000 are credited to the southern end of the continent; All the rest is in the extra tropical region of the north, mainly on the slopes of the Himalayas or in the valley of the Brahmaputra. In Ceylon the area under tea in all stages is 250,000 acres. It follows that of the tea cultivation of India and Ceylon (aggregating 580,000 acres, or perhaps now the round 600,000) 260,000 acres are within the tropics, between 7° and 11° north of the equator, the Ceylon portion of it at least experiences no real winter, although there are occasional frosts in and around Nuwara Eliya and cold still more pronounced on the Nilgiris. The conditions under which 320,000 acres of this truly cosmopolitan plant are cultivated in the far north of India are very different, there being an unmistakable winter and a cessation of flushing from November until March. The crop grown in continental India is already equal to 110,000,000 lb.; and even if no addition is made to the cultivation, the quantity is likely to rise to 150,000,000 in the course of a few years. The quarter of a million acres of tea in Ceylon will certainly yield 66,000,000 lb. in 1891 and the round 70,000,000 is not improbable, while our island, at the present rate of progress, is likely to show an export of 120,000,000 lb., by the time India reaches 150,000,000, say by 1895. With an aggregate production this year of 180,000,000 lb., and the early prospects of

From India	150,000,000 lb.
" Ceylon	120,000,000 "

or a total of 270,000,000 lb., there is need that both countries should bestir themselves to secure, in addition to expanding old markets, the opening up of new. Especially is this a necessity in the case of Ceylon, where the annual increase is not moderate as in India, but, "by leaps and bounds." This is not the time to withhold liberal help for an effective effort to capture the American and other markets by the proper representation of our great staple products at the Chicago World's Fair.

EMIGRATION INTO ASSAM.

There are two things which make Assam interesting to the outer world: one is that the little Province practically represents the north-eastern frontier of India, and comes into contact with almost as great a variety of savage and independent races as Burma itself; the other is the fact that Assam and its tea gardens swallow up some of our surplus population. The

migration cannot be compared with the depletion of Ireland, it is true. Assam in the first place is hardly an Indian America in the temptations it offers to settlers, nor is it likely that any emigrants would find their way thither but for the labours of the agencies variously known as sirdars, arkatis, contractors and so forth; still Assam does absorb a large number of emigrants. The figures for the last five years are 30,894, 36,463, 46,293, 55,658, and 36,080. A total migration of over 200,000 souls in five years is a not inconsiderable drain from the crowded parts in India, and it is important to notice that the whole of this relief to the congested districts is effected by private enterprise and is paid for ultimately by the British tea drinker. Government interferes indeed in regulating the routes by which the emigrants travel, and provides depots and medical and other supervision. But this is chiefly paid for by the planters, which means of course that the money comes ultimately and very properly out of the pockets of the drinkers of Assam tea. What becomes of the emigrants after they reach their bourn seems doubtful. There appear to be no reliable statistics of coolies who make the homeward journey, though it is stated that many do return, while some even return temporarily and take friends and relatives back to the tea gardens. Again some settle in Assam as cultivators though the proportion, so far as the Provincial statistics show is disappointingly small. At the end of 1890 the total labour force of the Province was over 400,000. One might fairly hope that a large part of these would take up land, which, in the Assam valley at all events is held on remarkably easy terms. Yet the land known to be held by time-expired coolies is only 32,000 acres or thereabouts. If the row proverbial three acres and a cow be attributed to the settlers, this gives us only about 10,000 imported cultivators in the Province, out of a population of some five millions, as the result of many years of migration. That so many as 10,000 (and our estimate is probably a low one) can be found goes to show that there is no inherent reason why coolies should not save enough money to set up farming on their own account. Possibly coolies in time acquire a taste for an existence in the lines, as soldiers have been known to acquire a passion for barrack-life. It seems curious, however, to the independent observer that it is not possible to find out more accurately what becomes of coolies on the expiry of their agreements. Every coolie's history is probably known to his employer, and it would seem to be within the limits of possible ingenuity to put this information into a concise tabular form.

The chief interest of the last Provincial Report on Immigration lies, however, in the fact that immigration into Assam has suffered a notable check; not only is this the case, but planters, we are told go further afield for their labour. There is a marked increase in the importations from Madras, where the hilly parts of Ganjam afford a field for recruitment not dissimilar to Chota Nagpur. The drain on Chota Nagpur seems to be telling at last, while gold mines and coal mines and other local temptations probably provide a serious competition with the efforts of the agents of Assam planters. But Chota Nagpur was still far and away ahead of the other exporting districts in 1890.

The district of Sylhet, with a labour force of 82,000, seems to have got all the labour it wants, and recruits but little. This is the more satisfactory that many of the largest tea gardens in Sylhet are comparatively new. Probably the same is true of the neighbouring district of Cachar, which only increased its labour force by less than two per cent in 1890. Apparently many of the gardens in the Surma valley are favourably situated from a coolie's point of view, are healthy, or well supplied with bazaar produce, circumstances which not only make it cheaper to import labour, but enable the managers to maintain a larger labour force in proportion to the work to be done. This again helps to make the gardens popular. On the other hand, the great tea-planting districts of upper Assam, which employ hard upon

100,000 coolies each, still demand fresh supplies. The journey to these districts is comparatively long and expensive, and the conditions of labour are probably less easy than in more accessible districts. Everything that tends to make the acquisition of coolies difficult and expensive tends to make the coolie's lot less easy, in as much as the expense of importation tends to encroach on the wages fund of the Province.—*Pioneer*.

FISH-CURING.

From the report of the Board of Revenue on fish-curing operations during the year 1890-91, it appears that the number of yards actually worked in the Presidency during the year was 143, or one more than in the previous year. The weight of fish brought to be cured increased from 43,496 tons to 50,194 tons, or by 15.3 per cent. The increase appears in five sub-divisions, while in the remaining three—Nellore, Chingleput, and Negapatam there was a decrease, which is ascribed to a bad fishing season on the East Coast. The average quantity of salt issued to each maund of fish cured fell from 12.16 lb. in 1889-90 to 11.82 lb. in the year under report. In the sub-divisions the proportions of salt issued varied from 8.46 lb. in Chicacole to 14.22 lb. in Negapatam. The experiments conducted by Government officers exhibit similar variations, the largest quantity of salt used being in Tinnevely (15.56 lb.), and the smallest in Chicacole (9 lb.), the average for the Presidency being 13.32 lb. Departmental experiments in fish-curing were conducted on a larger scale than in previous years, the quantity dealt with being 2,452 wauuds against 511 mauuds in 1889-90. No information is afforded in the report as to whether the article thus cured is more appreciated by the public than that cured in the ordinary manner, and as to whether it commands a higher price in the market. The quantity of salted fish exported by sea amounted to 3,610 tons against 2,750 tons in the previous year, and the average value of the exported article shows a slight rise, being 1 anna 3-6 pias per lb. against 1 anna 3-4 pias in 1889-90. The financial results of the industry, remarks Government, are, as usual, very satisfactory, the surplus of receipts over charges being Rs15,190 and the net gain to Government from the commencement of operations amounting to Rs3,269.—*Madras Times*.

ECHOES OF SCIENCE.

The question of sterilising water for the supply of cities by means of electricity has again cropped up in a paper by Mr. R. Meide Bache, recently read before the American Philosophical Society. Mr. Bache has made a number of experiments, which go to prove that a current of electricity sent through water destroys bacteria; but, as in prior experiments by others, it is still doubtful whether the liberated oxygen or the electricity itself kills the germs. In any case the water is at least partially sterilised.

Yeast has been successfully tried as a remedy for typhoid fever by Drs. Embling, Lempriere, and Thomson, of the Alfred Hospital, Melbourne. Thirty-seven cases were treated, ten being severe, the temperatures reaching 104deg.; eight were moderate, the temperatures being 103deg.; eleven were mild, and eight were very mild, the temperatures reaching 102deg. In every case the recovery took place without a relapse. There is a theory to the effect that relapses are due to reinfection from the intestine, and Dr. Thomson remarks in his report that yeast should destroy the bacilli in the intestinal tube, and so prevent reinfection.

Mr. Edison is keeping his new electric railway a profound secret at present, perhaps to avoid piracy, but he claims that his system will supplant all other railways, at least for traffic in cities, and he declares that the Broadway and Third Avenue Car Companies will soon regret their recent enormous expenditure

for making cable tramways, for his new system can be installed with very simple changes in the roadway. All that is publicly known about the system is that it comprises a new electro-motor and a conductor which is hidden in the track itself.

It is rumoured that he employs a current of low voltage, or electromotive force, and that he can get his current from the track without much loss of power, even in muddy weather, when the insulation must be low. He is now building a large electrical locomotive for this purpose in his private factory at Orange, New York.

The Philadelphia and Reading Railroad Company of the United States recently ran a train consisting of a "D 33" engine and cars, amounting to a load of 169 tons in all, at the surprising speed of 90.4 miles an hour. The run took place on a mile of level track following a descending grade of 37 feet per mile. The New York Central Railway has also accomplished 438 1-3 miles in 425min. 14sec.—or over 60 miles an hour, the locomotive being a Schenectady engine.—*Globe*.

SOME ACCOUNT OF THE NUTMEG AND THE CULTIVATION.

By THOMAS OXLEY, ESQ., A. B.,

Senior Surgeon of the Settlement of Prince of Wales Island, Singapore and Malacca.

(From the "Journal of the Indian Archipelago and Eastern Asia.")

The Myristica Moschata, or true Nutmeg, is known to botanists as a tree belonging to the Natural Family Myristicaceae, Class Dicotyledonae, Order Monodelphia of the Linnæan System. It would be superfluous to enter into a minute description of a plant already so well described, particularly by Roxburgh: I shall therefore merely notice some peculiarities that deserve attention. The tree, like many of its class, has a strong tendency to become Monocæmic, and Planters in general are rather well pleased at this habit, thinking they secure a double advantage by having the male and female flowers on the same plant. This however is delusive, and being against the order of nature, the produce of such trees is invariably inferior, showing itself in the production of double nuts and other deformities. It is best, therefore, to have only female trees with a due proportion of males. But few have the moral resolution to cut down the Monocæmic tree, on the principle that something is better than nothing, but they forget that the Monocæmic plants having much fewer flowers, it will take three or four of them to yield the same amount of pollen as the true male, and as for the produce yielded by such trees, that of one good female is worth a dozen of the other.

The female flowers, which are merely composed of a trifid calyx and no corolla, when produced by a tree in full vigor, are perfectly urceolate, slightly tinged with green at the base, and well filled by the ovary, whereas the female flowers of weakly trees are entirely yellow, imperfectly urceolate, and approach more to the stamiferous flowers of the male.

The shape of the fruit varies considerably, being spherical, oblong and egg shaped, but "ceteris paribus" the rarer they approach sphericity of figure, the more highly are they prized.

There is also a great variety in the foliage of different trees, from elliptic, oblong and ovate, to almost purely lanceolate shaped leaves. This difference seems to indicate in some measure the character of the produce, trees with large oblong leaves appearing to have the largest and most spheric fruit, and therewith small lanceolate leaves being in general more prolific bearers, but of inferior quality.

The object of this paper being practical, I shall confine myself as much as possible to a record of an experience extended over a period of some 20 years; and as the subject of spice planting has now become one of deep interest to very many of the Strait's settlers, I entertain a hope of being able to offer

some useful hints to those already engaged in such operations, and a tolerably safe guide for future speculators. But I am by no means disposed to think that I can exhaust the subject as leave nothing for future writers, being fully persuaded in my own mind that the cultivation of the nutmeg can still be greatly improved, and that in fact very little science has as yet been expended upon it.

The Nutmeg Planter, to use Colonel Low's expressive words, "must have the bump of perseverance mystically developed, and be impervious to compunctious feelings on opening his purse"; the combination also of an enthusiastic temperament with untiring patience is desirable. If he be in haste to get rich, let him attend to some other pursuit; but to has this consolation, that nutmeg planting properly conducted, although slow, is sure, and when brought to a certain point, safe and enduring; and he has the further consolation of knowing that nature has bestowed upon him a monopoly, for the nutmeg tree appears to be confined within comparatively narrow limits. Whilst its congener, the clove, has been spread over Asia, Africa, and the West Indies, the nutmeg refuses to flourish out of the Malayan Archipelago except as an exotic, all attempts hitherto made to introduce it largely into other tropical countries having decidedly failed.

The Island of Ternate, which is in about the same latitude as Singapore, is said to have been the spot where it was truly indigenous, but no doubt the tree is to be found on most of the Moluccas. At present the place of its origin is unproductive of the spice, having being robbed of its rich heritage by the policy of the Dutch, who at an early period removed the plantations to the Banda Isles, for better surveillance, where they still remain and flourish. But although care was formerly taken to extirpate the tree on the Moluccas, the mice feeding Pigeons have frustrated the machinations of man, and spread it widely through the Archipelago of islands extending from the Moluccas to New Guinea. Its circle of growth extends westward as far as Penang, where, although an exotic, it has been cultivated as a mercantile speculation for many years with success, so much so that doubtless the Penang Planters think themselves more in a situation to give than receive advice. I shall therefore beg any of those magnates who may chance to cast an eye on this paper, to bear in mind that what they read is more peculiarly applicable to Singapore than any other locality, and that moreover the plans laid down have succeeded here. Westward of Penang, there are no plantations, looking at the subject in a mercantile point of view. The tree is to be found, indeed, in Ceylon and the West Coast of India, but to grow it as a speculation out of its indigenous limits, is as likely to prove successful as the cultivation of apples and pears in Bengal.

In the Banda Isles, where the tree may be considered as indigenous, no farther attention is paid to its cultivation than setting out the plants in park under the shade of large forest trees with horizontal branches, called "Canari" by the natives. Here it attains a height of fifty feet and upwards, whereas from 20 to 30 feet may be taken as a fair average of Straits trees; but notwithstanding our pigmy proportions, it does not appear from all I could ever learn, that we are relatively behind the Banda trees either in quantity or quality of produce, and I am strongly impressed with the idea that the Island of Singapore can compete with the Banda group on perfectly even terms. Our climate is quite unexceptionable for the growth of the nutmeg, being neither exposed to droughts or high winds; and although we may lose by comparison of soils, we again gain by greater facilities of sending our produce to market, by the ability of obtaining abundant supplies of manure, and any amount of free and cheap labour.

I shall now endeavour to lead the Planter step by step on his wary way, but just to cheer him a little, he may have the assurance that a nutmeg plantation well laid out and brought up to perfection, is one of the most pleasing and agreeable properties that can be possessed. Yielding returns more or less daily throughout the year, there is unceasing interest,

besides the usual stimulus to all Agriculturists of a crop time, when his produce increases to double and quadruple the ordinary routine.

Trees having arrived at 15 years growth, there is no uncertainty or fear of total failure of crop, only in relative amount of produce, and this, as will be seen, is greatly in the Planter's own power to command. It is against reason to suppose that a tree always in flower and fruit will not expend itself if left to unaided nature; it must be supplied with suitable stimuli to make good the waste; therefore he who waits nuts must not be sparing of manure, but of this more directly.

The first requisite for the Planter is choice of location. It is true that the nutmeg tree, aided by manure, will grow in almost any soil where water does not lodge, but it makes a vast difference in the degree of success, whether the soil be originally good, or poor and improved by art. The tree thrives not in white or sandy soils, but loveth the deep red and friable soils formed by the decomposition of granitic rocks and tinged with iron, and the deeper this tinge the better. I am therefore inclined to think that iron in the soil is almost necessary for the full development of the plant. If under the beforementioned soil there be a rubble of iron-stone at 4 or 5 feet from the surface (a very common formation in Singapore), forming a natural drainage, the Planter has obtained all that he can desire in the ground, and needs only patience and perseverance to secure success. The form of the ground ought to be undulating, to permit the running off of all superfluous water, as there is no one thing more injurious to the plant than water, lodging around its roots, although in order to thrive well it requires an atmosphere of the most humid sort and rain almost daily. Besides the form of the ground, situation is highly desirable particularly as regards exposure. A spot selected for a nutmeg plantation, cannot be too well sheltered, as high winds are most destructive to the tree, independently of the loss occasioned by the blowing off of fruit and flower.

At present there is abundant choice of land in Singapore, the greater portion of the Island being as yet uncultivated, and much answering to the above description. The land can be purchased from Government at the rate of from 5 to 10 Ropes per acre in perpetuity. I would advise the man who wishes to institute a plantation to select the virgin forest, and of all things let him avoid deserted Gambier plantations the soil of which is completely exhausted, the Chinese taking good care never to leave a spot until they have taken all they can out of it. A cleared spot has great attraction for the inexperienced, and it is not easy to convince a man that it is less expensive to attack the primitive forest, than to attempt to clear an old Gambier plantation overrun with the *Lalang* grass; but the cutting down and burning of large forest trees is far less expensive than the extirpation of the *Lalang*, and as the Chinese leave all the stumps of the large trees in the ground, it is also more difficult to remove them in this state, than when you have the powerful lever of the trunk to aid you in tearing up their roots, setting aside the paramount advantage that in the one case you possess a fresh and fertile soil, in the other an effete and barren one, for if there be any one plant more than another capable of impoverishing and wearing out land, it is the Gambier plant.*

(To be continued.)

A BIG CACAO LEAF.—A correspondent writes:—"The leaf I send by today's post is off an experimental tree round the bungalow, I measured it 23 in. by 7 in. What do you think of it as a specimen? The tree is about five years old, healthy and in bearing under slight shade." The leaf is certainly a grand specimen, but the cacao trees are distinguished for large leaves.

* Any observant visitor to Singapore will notice this. Deserted tobacco trunks in Java alone are more exhausted.—ED, L. R.

FIBRE CULTIVATION.

(This and the following article are Extracts from the Annual Report on the Bahamas, by Governor Sir Ambrose Shea, K.C.M.G.)

Steady progress continues to be made in this industry, with increasing faith in its value and permanence. A report of the cultivation to the present time has been prepared by order of the Government, which, though strictly accurate, would not convey true impressions to those at a distance.

The report speaks of 4,100 acres being already planted with 2,500,000 of plants, but it states that there are also 1,300,000 plants in nurseries, which, being in course of growth, adds 50 per cent. to the active cultivation, making an aggregate of over 6,000 acres. Plants are now kept much longer in nurseries to lessen the cost of weeding, which is an expensive operation, and annually attended to after the plants are set out in the fields.

There has been some question as to the time to bring the plantings to maturity, but four years is now the accepted period, while plants retained in the nurseries, as above stated, will mature in three years. There is but little to add to former reports on this enterprise, which has passed out of the experimental stage and will not probably present any new features of interest until exports of fibre begin, which will be, on a moderate scale, in 1892, then developing annually into proportions of increasing importance.

The value of fibre, like that of other products, will, of course, be subject to market condition from time to time, but, in the natural order of things, it will ever be the main export and, regarding all the surrounding circumstances, it is difficult to see how it can fail to pay present investors handsomely and to be, to them, a source of income less liable to fluctuations than is the case with most commercial adventures. The time is now approaching when the machines for separating the fibre from the leaf will acquire practical importance; of those now in use none seem to meet all the requirements. Some of them clean the fibre well; but the process is wasteful, and the correction of this defect is the object to be accomplished. With so great an interest at stake we must suppose inventive genius will be found equal to the occasion. Professor Edison has directed his attention to the matter of decortication and he hopes he has found an effective method which avoids waste. The treatment is by solution of crude petroleum, and this Government is now in communication with the Professor. If the results meet our requirements, a most important end will be attained, which will have the further advantage of enabling small cultivators to dress their own leaves instead of being compelled to sell them at a loss to a large neighbouring planter, who is able to procure a machine.

The process being enterprised by Professors Edison embraces other and most valuable interests in this Colony. Many thousands of tons of pine-apple leaves are now annually left to waste. The fibre commands a high price, from £60 to £80 a ton, for use in fine textiles. The small quantity now produced comes from China, where it is roughly and expensively prepared for want of a machine sufficiently delicate to extract the tender fibre without injury. The proposed mode would seem to meet this difficulty, as all strain or friction is avoided, and the result of pending inquiries is looked for with great interest. The immediate effect of successful experiment would be to turn a waste product into an article of much value, adding substantially to the returns of pine-apple cultivation and this process may be applied to the growing crop. It is understood that the same solution may be used many times, and, if present hopes are realised, the petroleum will be admitted free of the duty now imposed.—Trinidad Agricultural Record.

maintenance is much assisted by these crops. Cotton shows an increase, being £1,593 in value compared with £1,074 in 1889. There is no reason why this business should not be extensively prosecuted, as most of the islands are well adapted for its cultivation. It is hoped that the presence of strangers now coming in to pursue the fibre industry will act on cotton production, to the advantages of which their attention cannot fail to be directed. It is quite possible that, in time, cotton may be found only second to the fibre in the category of exports from the Colony. The pine-apple crop realised £49,795, as compared with £25,558 in 1889. Of canned pine-apples there were exported 26,799 cases, valued at £6,126, and in 1889 the export was 21,683 cases, with a value of £4,500. In oranges there was an export of £3,961, the output of 1889 having been £3,040. Careless culture and a reckless mode of shipping, very often in bulk in vessels' holds, must militate against the success of the orange growers. There are advantages for the cultivation of oranges in these islands not known in Florida, as we are proof against frost, which often visits that country. This branch of employment may also be favourably affected when men of enterprise from outside, appreciating the opportunity, use it with energy and the application of well-ordered methods of packing and shipping.—Trinidad Agricultural Record.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, JANUARY 1ST, 1892.

[No. 7.]

THE INADEQUATE SAMPLING OF TEAS.

What has been stated to our London correspondent relative to the above matter may be accepted as fully correct, we can readily understand the strong feeling on the subject evinced by the Indian Tea

Planters' Association, and can sympathize with the steps that body has seen fit to adopt with reference to it. It is very certain, of course, that a grievance of such a character must be fully shared in by our own planters, and we can only wonder that it has not before evoked remonstrance by them. We are not aware, however, if the facts as now stated to us—if they be really facts—have on any previous occasion received public notice. Some of our upcountry friends and correspondents may possibly have heard complaints of this nature, but if so they have not been communicated to us. The Indian Association may be able single-handed to have the evil remedied, and we are quite sure that Mr. Leake and the Committee of the Ceylon Association in London well co-operate heartily with their Indian *confrères* in the endeavour to secure such a result. But if their combined efforts should prove to be unable to secure success, we hold that it will be the duty of our Planters' Association to unite with both the bodies named and so impress upon the brokers its feeling on the subject as to enforce the observance of what is but a rule of simple and necessary justice to our hard-working tea planters. For how can it be expected that we can avoid hearing of complaints of the quality of Ceylon teas being constantly not up to sample, if, as a matter of fact, those samples have never been in any way tested! As we understand the allegation made, it is that in the rush and hurry of business as it is at present conducted, in the haste to put teas which arrive on the market directly they are landed, the sampling if done at all is most inefficiently done. It would seem to be the case that in very many instances a handful of tea is just taken out of one of the chests of a break, and that without even the necessary

preliminary of liquoring and tasting this is offered as a sample of the contents of perhaps one hundred chests. Now we know from experience, from repeated instances mentioned to us, that perhaps not even two or three of the chests in a break of the size mentioned would fairly represent the average quality of the whole. Some defect in packing on the estate, or injury arising from rough usage or from the unseasoned wood of a particular box, may cause the one selected to be of very inferior quality to the great bulk of such a quantity of tea. As a matter of fact, we should ourselves say that a sample for each five boxes should be subjected to the most careful tasting and description before an average sample should be determined upon. We can fancy we hear shippers on this side. But we can hardly think that, if the difficulty had been fairly represented to them, if the possible loss arising out of undue haste had been fully explained to them, these would continue a course of insistence almost certain to be fraught with bad financial results to themselves. They would, we should think, moderate their demands as to speed of disposal so as to give the brokers a chance of carefully sampling their teas before offering them to public sale. Doubtless we shall soon hear more particulars as to this matter: At present we are without details, and have only heard the statement of one side, so we must suspend judgment as to the degree of blame to be awarded and as to the parties to whom it should be imputed. But although thus compelled to await fuller information to do so, this does not detract from the necessity for calling particular attention to the subject; for if what is stated is practised on any extensive scale, the fact may go largely towards accounting for the very seriously low prices that our teas have been for some months past fetching at the London sales.

BOGUS CEYLON TEA IN ADELAIDE.

A correspondent writes as follows:—

"A friend of mine bought in Adelaide the 1 lb. packet of tea herewith sent for 2s. It bears a label, 'Pure Battigalla Ceylon Tea.' Is there such an estate in Ceylon, or do you think it is meant for 'Battigalla'?" You can make any use of this as you may think fit. Have it tested to see if it is Ceylon tea."

There is no such tea estate in Ceylon, and this, no doubt the person who adopted the false name for a fraudulent article well knew. The opinions of brokers are most decidedly adverse to the so-called Ceylon tea. Mr. A. H. Thompson writes:—

"I have tested the tea. I think the Ceylon men should go for this Company, as I am sure 50 per cent

of it is China to begin with, and the small amount of real Ceylon tea in it is worth about 6d or 25 cents a pound in Colombo: in fact I can buy a better tea at 27 cents in Colombo that will knock it clean out."

Messrs. Somerville & Co., to whom we referred for an opinion, report as follows:—

"Mark Batticola, description broken tea, London value 5d. Colombo equivalent at exchange 1s 5d = to 20c. to 21c. Remarks—blackish, flaky, dusty broken tea: little leafy; liquor thin common, with China shantam flavor.

"P. S.—From the taste of the liquor we are inclined to suspect a mixture of Ceylon and China tea (with a larger proportion of the latter), which however is difficult to trace in the dry leaf, as the tea is very broken and hardly a whole leaf perceptible.

Infused Leaf.—Black."

So much for the "pure" Batticola tea. The sellers deserve to be prosecuted. They seem to have been ashamed to put their name on the packet.

RUBY MINING COMPANY (LIMITED).

Mr. Thomas Dickson, chairman, presided at the half-yearly meeting of the shareholders, and explained that the object was simply to submit the directors' report on the working for the first six months of the year. No accounts were presented, as they were only rendered once in the twelvemonth. He might say he had nothing particularly encouraging to lay before them, or anything the reverse. The mine was one of the most peculiar in the world to deal with. If they found no ore they should be inclined to say they had enough of it, and they would go on no further. But such was not the case. They were continually coming across pipes and veins of ore running in all directions, and they were following these up, but they had not yet succeeded in finding the Bonanza which they were assured must exist somewhere. When the company was reconstructed, they were told by their managers and agents that it would be extremely unwise to abandon the working without a farther trial. The trial they were now making, and they were finding a certain quantity of ore, but not sufficient to make a dividend-paying company. True, their mills were shut down but they were now sending their ore to Salt Lake City to be crushed, with results fully as satisfactory as when they did the work themselves. Meanwhile their exploring was being well and economically done, and they had the utmost confidence in their agents and officers. The report was adopted.—*Pall Mall Gazette*, Nov. 4th.

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LIMITED.

Report of the Directors of the Scottish Trust and Loan Company of Ceylon, Limited, to the Fourteenth Ordinary General Meeting of shareholders, to be held within the Company's Registered Office, No. 123 George Street, Edinburgh, on Monday, the 26th day of October 1891, at 3 o'clock p.m.

The Directors present their Fourteenth Report, being for the year to 31st August 1891.

ESTATES IN COMPANY'S POSSESSION.—The year just closed has, as regards products, been the most successful in the history of the Company. The yield of both Tea and Coffee has exceeded expectations, and the prices obtained in the London market have been satisfactory. It will be observed from the Balance-Sheet that the value of Produce on hand at 31st August last represented a sum of £6993; and the Directors have to state that this valuation is confirmed by sales which have actually taken place subsequent to that date. The prices obtained for Cinchona during the past year have been somewhat disappointing. As in former years, the whole cost of tea cultivation has been charged against Revenue. On the Estate of Kaipogala, the Tea Factory referred to in last year's Report has been erected at a cost of £1760, and there has been expended one

Factory at Annfield and Alnwick sums amounting to £1000. The Directors propose to write off, as formerly, one-fifth of the total expenditure upon this account. The operations during the year at these Factories have been satisfactory, and a large quantity of leaf has been treated.

The Directors have further to report under this head that during the year they entered upon negotiations with the Ceylon Plantations Company for the sale of Ardallie, one of the estates belonging to this Company. These negotiations ended in the acceptance by the Directors of an offer of £7,000 for the estate as it stood at 1st April 1891.

MORTGAGES HELD IN CEYLON BY THE COMPANY.—This Account in the Balance-Sheet shows a considerable reduction as compared with the amount due at 31st August 1890. The sum of £3,000 referred to in last year's Report as a loss on Loans, has been written off, and sums amounting to £4,095, 16s 8d have been received from sundry Borrowers in reduction of and payment of Mortgages. The Company does not now hold any Rupee Loans. The interest on all Mortgages has during the year been paid with regularity, and the Directors have pleasure in recording that at the close of the financial year no interest was in arrear upon any of the Company's Loans. During the current year, the Mortgage Debt due to the Company will be further reduced.

DEBENTURE DEBT.—The liability of the Company under Debentures has, during the year just closed, been reduced by a further sum of £6,155, which represents a considerable saving in interest. At the ensuing terms of Martinmas, 1891, and Whitsunday, 1892, the Directors will be in a position to pay off the whole Debentures then falling due.

ACCOUNTS.—The balance at the credit of Profit and Loss Account is £7,705 6 9 and the Directors propose—
To pay a Dividend of 5 per cent, free of Income Tax .. £2,250 0 0
To pay a Bonus of 5 per cent, do. £2,250 0 0
To transfer to Reserve Fund £1,000 0 0
£5,500 0 0

Thus leaving .. £2,205 6 9 to be carried forward to next account.

The Dividend and Bonus will be payable on 11th November next.

Under the rotation fixed by the Directors, Mr. Henry Johnston, Advocate, retires from office at this Meeting; but he is eligible for re-election in terms of Section 14 of Articles of Association.

The Auditor for the current year falls to be appointed.

By order of the Board, FRANCIS A. BRINGLOE, Secretary.

Edinburgh, 19th October 1891.

GEMMING AND MINING COMPANY.

(From the *Dwarf*, Nov. 3.)

I should much doubt, after the collapse of the Burmah Ruby Mines, Limited, which was brought out under the auspices of Mr. Streeter, whether the Sapphire and Ruby Mines of Montana will be readily subscribed for even by our gullible British public. It is well-known that Tiffany, the eminent New York Jeweller, has not formed a very high opinion of the value of Montana stones, and refused to purchase the property or to assist in bringing it out as a Limited Company. If the ground is so valuable it is extremely unlikely that Cousin Jonathan would have allowed it to go begging in London.

I hear that Streeter will shortly be asked to bring out yet another sapphire mine, this time in Cashmere; and the fact that Colonel Parry Nielsel's name appears on the list of Founders of the Montana Company, rather strengthens me in my belief in the rumour. Recently some very valuable finds of sapphires have been made in Cashmere, and experts are now inspecting the supposed site of the mines.

I also hear of a valuable Mexican silver mine, which will shortly be placed on the market; the argentiferous deposits cover an extensive area, and are unusually rich in ore.

A valuable West-End business, possessing a practical monopoly, is also to be converted into a Limited Company, as the fortunate owner has already realised a large fortune by the business, which is still increasing, and is only converting it into a company to lessen his own individual labour, and to provide for his family. This should afford a far safer investment than even sapphires or rubies.

TEA ANALYSIS.

As an instance of the difficulties to be met with by the unscientific enquirer after truth in the matter of tea analysis, we give the following extract from the *Analyst*:—

"Examination of China Teas. By P. Dvorkovitch. *Journ. of Anal. and Applied Chem.*, Vol. V., p. 345.—The author estimates the amount of theine as follows—10 grammes of tea are carefully ground and 200 c.c. boiling water are poured over it. Five minutes later the infusion is decanted. This operation is repeated three times. The tea is then boiled twice with 203 c.c. water each time, so that the water is not coloured, or but slightly so. The extract thus obtained is diluted to one litre. A portion of this extract is washed with petroleum ether three times, in order to remove the oil and the brown substance found in tea, to which Mulder has already called attention. Then 600 c.c. of this aqueous infusion, corresponding to 6 grammes tea, are taken, washed with petroleum ether, 100 c.c. of a caustic baryta solution, containing 4 grammes in 100 c.c. are added to it, well shaken and filtered immediately from the precipitate obtained. 583 grammes of the filtrate, corresponding to 5 grammes of tea, are then mixed with 100 c.c. of 20 per cent salt solution and the mixture, shaken with chloroform three times, about 400 grammes chloroform being used in all. The solvent is then removed by distillation, and the residue of theine dried at 100° C. Absolutely white theine is obtained in beautiful needle-shaped crystals.

"The washing with petroleum ether is necessary, first, for the removal of the ethereal oil, and next for that of the brown substance alluded to. One and the same tea, washed and not washed with petroleum ether, showed a difference of 0.6 p.c. in its contents of theine. This method gives higher results than that of Peligot, Mulder, or J. Bell. All methods based on Mulder's principle, viz., on the boiling of the tea with magnesia or lime, give results which are too low, on account of the partial destruction of the theine with evolution of ammonia.

"The preliminary fermentation, to which all black teas are subjected, destroys a varying proportion of the tannin. The quality of the tea, to a very great extent, depends upon the method of fermentation, the astrigency not only being lessened thereby, but the aroma being developed. The author worked out a method applicable to the determination of the tannin and to its products of fermentation, based upon the Loewenthal principle. A solution of tea, 10 grammes to the litre is made precisely as above described, 40 c.c. being diluted with 500 c.c. of water, and titrated with permanganate, with indigo carmine as indicator. 80 c.c. of the tea solution are then mixed with 20 c.c. of caustic baryta containing 4 grammes. In 100 c.c. the precipitate is filtered off and 50 c.c. titrated with permanganate. The quantity of permanganate thus expended indicates the quantity of the products of the decomposition of tannin; that is to say, the degree of fermentation to which the leaf was subjected. The longer the fermentation lasted, the more of these products. The percentage both of tannin and the products of fermentation are calculated from the oxalic acid standard of the permanganate solution, 63 grammes of oxalic acid corresponding, according to the author to 31.3 grammes of tannin, and not to 41.2, as found by Neubauer.

"Twenty-nine samples of tea were examined. The best qualities contained the largest amounts of theine.

This was manifested more strongly when the ratio of theine to the total amount of tannin and products of fermentation was calculated. The theine varied from 2.14 in the cheapest, to 3.21 in the best tea; the percentage of theine to total tannin from 16.0 to 24.52.*

"It need hardly be added that these deductions are in direct contradiction with those of many other observers."

The last sentence is evidence of the uncertainty of chemical deductions.—*H. and C. Mail*, Nov. 6th.

CAN WE MAKE IT RAIN.

The October number of the *North American Review* contains two articles under the somewhat startling heading "Can we make it rain?" The first is by General Robert G. Dyrenforth, who has been attempting, and, as he believes, successfully attempting, to produce rain in districts afflicted with drought, by means of dynamite and other explosives. In the second article, Professor Simon Newcomb, the eminent astronomer, tries to drown General Dyrenforth's arguments and conclusions in a cold shower of sarcasm. It has been frequently noticed that heavy cannon-firing has been followed by rain. In 1870 an American author, Mr. Edward Powers, published a book entitled "War and the Weather," in which it is stated that 198 battles of the Civil War, including every battle of importance, were immediately followed by downpours. Results such as these, however, need very careful criticism before any definite conclusion can be drawn from them, and it occurred to several distinguished men in the United States that the question was one of sufficient importance to deserve experimental investigation. A scheme promoted in 1874 by General Garfield, General William Sherman, and others fell through owing to lack of funds. But in 1890 the Hon. C. B. Farwell succeeded in obtaining from the Department of Agriculture and the American Government a sum of 9,000 dollars for a new project, which did not involve, like the former, the expense and difficulty of transporting a large number of cannon from the coast to a rainless district. General Dyrenforth was asked to take charge of the investigations, and he has now published the details of the first experiments made under his direction.

"On the 5th day of August," says General Dyrenforth, "our party arrived at Midland, Texas, a small station on the Texas and Pacific Railway, situated on the Llano Estacado, or Staked Plains, in a region which had been suffering from a severe drought of several months' duration, and a lack of good rains for several years. The party made its headquarters at a point twenty-five miles from Midland, in the midst of a dry prairie bearing little vegetation but scattered clumps of grass and low mesquite bushes, with here and there a cactus. The plan of operations was somewhat as follows:—Three lines were to be formed, each some two miles in length, and placed about one half mile apart. The first line to the windward was to consist of a large number of ground batteries, where heavy charges of dynamite and rack-a-rock powder would be fired at frequent intervals. The next line to the rear was to consist of a number of kites flown to a considerable height by electric wires, bearing dynamite cartridges suspended from them, to be fired high in the air. The third and main line was to consist of explosive balloons,

* So that the proportion of tannin in tea containing 3.21 per cent of theine would be about 12 per cent? —*Ed. T. A.*

(filled with a mixture of hydrogen and oxygen which would produce terrific 'air-quakes' at intervals of one to two hours during the day or during the continuance of the operation.)

Some difficulty was experienced with the kites their wires being often broken by the strong wind which prevailed, and consequently the dynamite explosions at high altitudes seem to have been a failure, but the rest of the project was executed with results which are best described in General Dyrenforth's own words:—"The first operation was made on August 9. At this time the balloon apparatus had not been set up, and only the first line of ground explosions was brought into action. The ground batteries were operated for about an hour, beginning at 5 p.m., August 9, and reopened again for a shorter time at about 7 p.m. The weather was clear on the 9th, and the barometer stood at its nominal height at 7 p.m. At noon of the 10th clouds began to gather directly over the ranch, and during the afternoon and the evening a very heavy rain fell—nearly two inches—transforming the road ways into rushing torrents, and every hollow into a small lake." The next operation was performed on August 13, the ground batteries being kept in action for twelve hours, and the balloon explosions being also brought into play. The meteorological instruments gave no indication of approaching bad weather, but "late in the afternoon heavy clouds gathered and formed, and rain fell in torrents for 2½ hours over the entire southern and eastern portion of Andrews County and most of Midland County and the counties to the south and west of it."

The third and final operation was begun at 11 a.m. on August 25. At 3-30 the barometric pressure was slightly below the normal, but the atmosphere was very dry. The wind blew from the south-east (the usual direction) at a velocity of 18-8 miles per hour, and the sky was clear, except for a few very light scattered cumulus clouds, estimated to be at a height of more than two and a half miles. Seven balloons were exploded, and the ground batteries seem to have been in action for twelve hours. "At 11 p.m. the firing ceased, and our weary party immediately retired for the night. At 3 a.m., however, the heavy rolling of thunder disturbed the sleepers, and, looking out to the west and north, heavy banks of cloud were seen advancing, almost constantly lighted by most brilliant lightning. An hour later the rain began to fall in torrents on the ranch, and did not cease till 8 a.m. The northern portions of this country received the most thorough watering they have had for the past three years, and the reports from incoming cowboys indicate that the storm extended over many hundreds of square miles. Besides these three heavy storms, which occurred after the principal operations," continues General Dyrenforth, "not less than nine showers of much less importance occurred during the sixteen days of our experiments—a most extraordinary occurrence in this locality, and especially at this season of the year. That these results were not produced at an excessive expense of material may be seen from the fact that in the entire series of experiments only two tons of iron, one ton of sulphuric acid, a quarter of a ton of chlorate of potash and manganese dioxide, and one ton of rock-a-rock powder and other explosives were consumed, none of which are expensive materials."

In the opinion of General Dyrenforth, those experiments clearly demonstrate, first "that the concussions from explosions exert a marked and practical effect upon the atmospheric conditions in producing rainfall, probably by disturbing the upper currents;" and secondly, "that when the

atmosphere is in a 'threatening' condition—which is frequently the case in most arid regions without any rain resulting—rain can be caused to fall almost immediately by jarring together the particles of moisture which hang in suspension in the air. This result was repeatedly effected during our operations, the drops sometimes commencing to fall within twelve seconds from the moment of the initial explosion."—*Public Opinion*.

INDIAN TEA DISTRICTS ASSOCIATION.

REGULATION OF SUPPLIES.

The following correspondence relating to this important subject—to which we are asked to give publicity—speaks for itself. We hope the brokers, whose responsibility in this matter is very great, will give due weight to the evident desire both of importers and dealers, and not print teas for sale until they are quite ready to be sampled:—

Indian Tea Districts Association,
Nov. 4th, 1891.

W. C. Price, Esq., Secretary,
Tea Brokers' Association of London,
118, Danster Hoase, E. C.

Dear Sir,—My committee had under their consideration yesterday the complaints of the trade with regard to the short time allowed for sampling and tasting teas offered for sale, and they desired me to call your attention to the remarks of the *Produce Markets' Review* of the 31st ult. on the subject.

Since then I have received a letter from the chairman of the Wholesale Tea Dealers' Association, a copy of which I enclose, and will thank you to take an early opportunity to lay the same before the Brokers' Association, as it rests with them in a great measure to meet the reasonable requirements of the trade.

I shall be glad to learn for the information of my committee, what steps are taken in the matter.—Yours faithfully,
ERNEST TYE, Secretary.

Produce Markets' Review, Oct. 31, 1891.

"If the importers continue to force their teas on the market in opposition to a declining enquiry, which is sure to take place shortly, as the retailer will to a great extent, be absorbed in attending to other goods, they must be prepared for a further decline in the comparatively moderate prices now ruling. No effort appears to have been made to give a reasonable time to sample the teas previous to the day of sale. In several cases this week catalogues have been issued only a day or two prior to the sales being held, consequently the teas were not ready for sampling when applied for, which necessitates a second application, and precludes the trade giving the attention to the teas they otherwise would do if a reasonable time were allowed for sampling and valuing."

London Wholesale Tea Dealers' Association,
4, Fenchurch Street, E.C., Nov. 3rd, 1891.

Ernest Tye, Esq., Secretary Indian Tea Districts Association.

Dear Sir,—I am directed by my committee to draw your attention to the inconvenience caused by the short time which is frequently allowed for sampling tea. In some cases the samples can only be obtained the day before a public sale, and often on the day of sale, and as there are many breaks it is often impossible to carefully taste the samples. As this system is opposed to the interests of the importer as well as the buyer, I trust your committee will take the subject into their favourable consideration, and arrange the public sales so that reasonable time may be allowed for drawing and tasting all samples.—Yours faithfully,
(Signed), FRANCIS PEER, Chairman.

—H. and C. Mail, Nov. 6th.

THE COAL INDUSTRY IN MALAYSIA.

[The following report came to us, marked, in a copy of the *Newcastle Daily Chronicle*, and so we insert it; but our readers will agree with us that Mr. Eekhout of Java would have done well to have

been far more diffident than he showed himself in discounting the future, while performance in the present is so small and imperfect. We think the Newcastle people showed great good nature in thanking the over confident Dutchman, who, on such utterly insufficient grounds, asked them to prepare for the extinction of their coal trade to the east. There is, no doubt, coal in the Malayan region, but it has not yet been discovered or brought to the surface in quantity and quality sufficient to justify such tall talk as Mr. Eekhout indulged in. Coal, some of very good quality, he might have remembered, is being extensively mined in British India.—Ed. O. O.]

Last night, in the Lovaine Hall, Barras Bridge, Newcastle, Mr. R. A. Eekhout, of Java, Fellow of the Royal Dutch Geographic Society, lectured, under the auspices of the Tynesido Geographical Society, on "The Dutch Indian Railways, and the Development of the Coal Industry in the Malaya Archipelago." Ald. Thomas Bell presided.

Mr. Eekhout said that everywhere in Sumatra, Java, and Borneo people were searching for coal, and were asking permission from the Dutch Indian Government for licenses to make mining investigations. Together with that industrial movement the extension of railway building was steadily going on in the Dutch possessions of the far East. For that reason, he thought that it might be of some practical importance to speak in the land of George Stephenson and in the heart of the coal trade, about what is going on that way in those splendid Eastern islands, and to draw their attention to the Dutch Indian railways and the development of the coal industry in the Malaya archipelago. He had lived ten years in Java, where he intended returning very soon, and where he had an opportunity of watching the whole movement very closely. Though in the Dutch Indies coal of different qualities had been known for a long time, it was only a quarter of a century ago that their exploration was taken in hand. The Dutch Indian Government itself worked it at that time in South and East Borneo for the benefit of its navy, but the quality did not give satisfaction. The exploration was at last abandoned, because it did not pay. In the meantime, the coalfields in the highlands of West Sumatra were discovered, and the mineral recognised to be of excellent quality; but it was not till 1888 that the Dutch Indian Government began to execute a serious plan for its exploitation by the building of the railway now in course of construction. There was coal in Borneo, Sumatra, and Java, but the coal in Java and Borneo was of inferior quality. It was suggested that these coals, also, would prove to be of the same quality as the best English kinds as soon as the mines were excavated deeper, and the lower seams opened out, where the coals would be of a far later formation. Before the end of this century, the Dutch Indian coals would count for a considerable portion in the prosperity of the Dutch colonies. A coaling station was to be established at Sumatra, in the Straits of Malacca. The Russian and French Governments had already officially declared that they intended to see that coaling station for their war vessels in the East, and it seemed that the French mail steamers were not unwilling to frequent also that coaling station, as they would benefit by the lower prices. Probably the British coal trade would not be affected by the coal trade in the Summa Islands for some years, but they must consider this fact, that within a certain time the whole consumption of more than two millions of tons a year in the region of the Dutch Indies would pass from the English coal to Dutch Indian coal. This would not only affect the British coal trade, but it would also affect her steamers which now plied to the East with cargoes of British coal, and returned with cargoes of produce. This export trade would then be finished, or at least diminished, unless they consented to sell British coals beyond the ocean at a loss, or to send the steamers without the coal cargoes to bring back the produce; this trade would pass from the hands of those who at present carried on the coal trade; and into the hands of the numerous European steam navigation companies

which provided at present the regular communication between the Orient and the Occident. He had already stated that the price at which the coal could be delivered at the ports was 18s.; he did not think that that would occur very soon, but it might be considered as the definite price of coal in the Malay Archipelago in the future. The coalfields could only be developed by the construction of state railways in the four great Summa Islands and by private enterprise with the interest guarantee of the Dutch Indian Government. Votes of thanks to the lecturer and Chairman concluded the meeting.—*Newcastle Daily Chronicle*, Oct. 24th.

PLANTING NOTES.

(From the *British North Borneo Herald*.)

We hear that Count Geloos, who since Mr. Christian's illness has acted as Manager of the Borneo Coffee Company's Estate, has engaged Malays at 25 cents per diem to work on the coffee estate. This is good news for coffee planters, and is much under the Estimates we have seen which provided for 30 cents a day per cooly. The Coffee Company are fortunate in having their interests in such good hands.

Coffee planting appears to be in favor with the natives. We hear that Mr. Little, Acting Resident West Coast, has requisitioned for coffee seed to be distributed among the chiefs of the Putatan district who have expressed a desire to plant Liberian coffee.

Mr. Henry Walker, Commissioner of Lands who has just visited Ceylon inform us that cocoa planting in Ceylon has ceased to be the precarious cultivation it at one time was now that shade has been introduced and that cocoa planters can now obtain very remunerative returns. One cwt. per acre is sufficient to pay the cost of working the estate and all above that (after allowing for the additional cost of collection and preparation) is profit. We have only to remind our readers that natives in North Borneo have long cultivated cocoa and we should say it is a plant that would be found very remunerative if cultivated on a large scale. The few trees at Silam (of the caracacas variety) have borne well and from notes made at the time it was shown that they came into bearing in the 4th year.

Mr. Walker reports that the patches of Liberian coffee on the Malapi estate on the Kinabatangan, of coffee and cocoa on the Seganan estate are looking remarkably well and are in bearing. Mr. Kennedy of the Seganan estate is fortunate in having soil of a very rich quality and the Bagahah range of mountains near the estates are said to have good soil.

A LADIES' TEA ASSOCIATION IN LONDON.

Housewives will be interested to hear that a Ladies' Tea Association has just been started. The promoters, two enterprising young ladies who have an interest in a tea estate in Ceylon, are Miss R. G. Bartlett and Miss A. M. Lambert, 2, Manchester-square-mansions. They told me that they mean to employ women only to help them in the carrying-out of their project of selling the best tea at a low price. From their deep knowledge of the subject one would think they had been in the tea trade for years. They have certainly managed to get the true knack of blending. When I went to see them the other evening I was given as a sample a cup of the "ladies' own"—the most delightful tea I have ever tasted. And I consider myself something of a connoisseur of tea, too. I drink it whenever I want a stimulant, which is about four times a day on an average. Fresh-made tea doesn't do one much harm. It isn't so demoralizing as wine, and isn't half so likely to give one a red nose. The worst thing that can be said of tea is that it is apt to make havoc of one's nerves.—"Miss Mantalini" in *Pall Mall Budget*, Nov. 5th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Oct. 24th.

CINCHONA.—The fortnightly bark actions on Tuesday were rather larger than usual, but the average standard of the Ceylon and Indian barks offered was exceedingly low. In fact, with the exception of two or three small parcels of yellow and grey barks, the figure of 4d per lb. was only twice reached. The catalogues comprised the following quantities of the various descriptions of bark:—

	Packages.	Packages.
Ceylon... ..	602 of which	602 were sold
East Indian ...	225 "	204 "
Java	64 "	84 "
South America...	532 "	307 "
West Coast African	295 "	295 "
	1,738	1,492

The unusually large quantity of African bark offered was nearly all of very recent import. It was fairly well competed for, and brought not altogether unsatisfactory prices. Much of it was badly harvested. The South American barks consisted exclusively of Calliays, partly of the flat variety normally met with at the drug auctions, and partly of cultivated Bolivian bark. The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works...	73,556
" Brunswick factory...	47,129
" Frankfurt o/M and Stuttgart works	41,555
Messrs. Howards & Sons	29,558
Agents for the American and Italian works ...	17,211
" Auerbach factory	13,805
Sundry druggists..	43,572

Total quantity of bark sold	266,386
Bought in or withdrawn...	25,129

Total quantity offered... .. 291,516

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots, and vice versa.

The next Amsterdam sales will be held on November 12th. The barks from private plantations to be offered on that occasion have not yet been got ready, but from the Government plantations there will be 20 tons of bark, including about 8 tons Succirubra, 1½ tons Officialis, and 19½ tons Ledger barks. One parcel of 42 bales ground Ledger stem bark analyses 97½ per cent.

OILS [VARIOUS].—Coconut oil remains very steady, the spots prices being 24s 9d for Ceylon (c i f, 23s to 23s 3d); and 28s to 29s 6d for Cochin c. l. i., 26s.

QUININE.—A transaction between two brokers is reported today at 9d per oz for second-hand German bulk. The quantity thus sold was only 2,000 oz. This is the lowest price the article has yet touched. It is said that a good deal of business has been done quietly lately, of which no particulars have been allowed to transpire, but it has all been done at the price quoted on the market. The United States official returns show that during the first nine months of 1891 the imports of quinine into the States have been about 500,000 oz. and of cinchona bark 200,000 lb. less than in the corresponding period of 1890.

PEARLS MADE TO ORDER.

An ingenious American has applied for a patent for making real pearls by artificial means. The material of which the oyster makes its pearl is certainly cheap and plentiful enough. If you take the shell of a pearl oyster and scrape or grind off the outer coat you find a sheet of about one-eighth of an inch in thickness of the precise substance which the oyster deposits around any foreign body, as a grain of sand, &c., which gets caught under its mantle, thus producing the pearl of commerce. Why not, says the experimentalist, take this sheet of nauro, dissolve it in acid, and then re-posit the pearl in layers about a shot or a pea suspended in the solution, thus copying the processes of Nature? The idea seems to open up vast possibilities, for in this way pearls of any size or shape might be procured at the fancy of the operator. There would be no difficulty in turning them out as large as billiard balls, or as footballs, even, for the matter of that. The trouble is that concretions thus

obtained are mere lumps of carbonate of lime, which entirely lack the iridescence which in the pearl is due to structure. This little difficulty has always stood in the way of the successful imitation of the oyster's production; but this latest inventor claims that he has entirely overcome it, so as to be able, not only to manufacture pearls, but also to coat articles with the material, just as spoons and forks are plated with silver. Whether the claim will or will not be made good in practice remains to be proved. A possibly easier and more certain mode of pearl production is indicated by an extraordinary treasure which was lately shown at the Smithsonian Institute. This was a pearl, the size of a pigeon's egg, of an exquisite rose colour, and the receptacle containing it was the original freshwater mussel in which it had been formed. The nucleus of this gem beyond compare was nothing more nor less than an oval lump of beeswax, which had been placed a few years ago between the valves of the mollusc, which, to protect itself from the irritation caused by the presence of the foreign body, at once proceeded laboriously to coat it with the pink nauro it secreted for lining its shell. The mussel was kept in an aquarium while engaged in its lengthy task. It belongs to a species common in American rivers, and it is suggested that the success of the experiment opens to everybody the possibility of establishing a small pearl factory for himself by keeping a tank full of tame mussels and humbugging them into making "great pink pearls" for him. Only the intending experimentalist is warned against avarice; the "nucleus" must be introduced well under the mantle of the creature; or it will not irritate sufficiently; and, above all, it must not be too large. A great surface takes a long time to cover, and multiplies the risks always attendant upon artificial culture. If one will be satisfied with pearls the size of peas the chances of success will be so much the more promising.—*Colonies and India.*

THE CELEBRATED MAHWAH TREE,
BASSIA LATIFOLIA.

The Department of Agriculture has successfully introduced for the first time into Australia this famous tree. It is a handsome tree, attaining a height of from 40ft. to 60ft., and a native of Bengal, in India, where it is carefully conserved for the sake of its annual crop of edible flowers. It possesses the advantage of thriving in dry stony ground, but will flourish in almost any kind of soil from the sea-level up to 3,000 ft. altitude. When the tree is a few years old it produces annual crops of flowers in great quantities. These contain about 50 per cent of sugar, and enter largely into consumption, and are considered a very nutritious and wholesome food both for men and for cattle, pigs, poultry, &c. Mahwah-fed pork has a high reputation. A single tree will yield from 200 lb. to 400 lb. of flowers annually. The flowers are eaten both fresh and dried. In a fresh state they possess a peculiar luscious taste. When dried the flavour has some resemblance to that of inferior kinds of figs. In a dried state they will keep a length of time, and are carried long distances for sale in the bazaars.

A wholesome spirit is distilled from the flowers, very similar to Irish whisky. This spirit is manufactured to a great extent in India, and the Government revenue from this source alone is considerable. The seeds yield by expression a large quantity of concrete oil (of the same value as coconut oil) which is used in lamps, to adulterate ghee, in the manufacture of candles and soap, and for oilinary purposes. The cake or residue is good food for cattle, and is a valuable fertiliser to worn-out lands. The timber of this tree is hard and strong, close and oven-grained, and is used for the wheels of carriages, railway sleepers, &c. A gum of some commercial value exudes from the bark.

The cultivation of this famous tree is receiving increased attention among planters and others in various parts of the world, as it is found to be a highly profitable commercial crop.

After giving a few of the trees to the Curator of the Botanic Gardens and the Director-General of Forests, there will be about 25 available for experimental purposes on the department's experimental farms at the Richmond River and amongst surrounding farms.—*Sydney Mail*.

[In Ceylon the tree called *illepai* by the Tamils and *migaha* by the Sinhalese (*Bassia longifolia*) is closely allied to the Mabwa tree of India. We have seen the road about two miles towards Dimbula from Nawalapitiya covered with masses of the white blossoms, as with wreaths of snow.—Ed. T. A.]

THE TEA TRADE.

The rapidity of the growth of the India and Ceylon, and of the decline of the China, tea trade is remarkably exemplified by the British Board of Trade returns for the first nine months of the current year. During that period the importation into the United Kingdom amounted to 160½ millions of lb. or 17½ millions more than in the same period of 1890; the home consumption was 149½ millions, or nearly 6½ millions more than last year; the exportation was 23½ millions, or 5 millions less than in 1890; and the stock of all kinds, on the 30th September, was 87 4-5th millions, against 81½ millions in 1890, and 88½ millions in 1889. The importation from India showed a decrease of 3 millions, and from China of 2 4-5th millions, the total being 61 millions from the former and 45 millions from the latter country; but Ceylon, with its 48½ millions, showed an increase of 1¼ millions of pounds for the nine months. Thus the importation from China was 2¼ millions less than that from Ceylon, and was no less than 6¼ millions less than that from both India and Ceylon. The quantity of India tea taken for home consumption was nearly 71 millions, or nearly twice that of China tea, namely 39 millions, or of Ceylon tea, which was 37½ millions. Two-thirds of the tea now consumed in the United Kingdom is obtained from India and Ceylon. The exportation of India and Ceylon tea is inconsiderable, as it amounted to only 8½ millions for the two products in the nine months; but the exportation of China tea was 18½ millions in 1891, and 24½ millions in 1890. The foreign demand for China tea in the London market thus fell off a fourth in the present year; and it will most probably continue to decline, for India and Ceylon teas are being largely shipped direct, via the Suez Canal, to the Continent, and when once the taste for them has been acquired consumers cannot be easily persuaded to go back to the unblended tea from China. The following extract from a London Market Report of the 21st ultimo shows the estimation in which India and China teas respectively are now held by the trade:—"The Indian auctions today totalled 8,177 packages, and passed throughout with spirit, prices ruling generally steady and strong for fine teas. At the China auctions of 10,572 packages, again a quantity of first crop Nungehwa and Kintucks about 5,500 packages were forced off at phenomenally low prices, quality considered. Good first crop Obing Wo's Kaisaw and Savanes also were hammered for the best prices obtainable, some being described in catalogue as fine thorny truly represented the light in which the importers received them before the sale."

A great deal has been said about the superior delicacy of the flavour of China tea; but the consumer who cannot afford the fancy price demanded for fancy China tea appreciates the broad, even rough flavour of the hiew from India or Ceylon tea, and is content to dispense with the possibly more refined flavour of the highest, or tho, to him, unattainable descriptions of China tea. Pound for pound the India and Ceylon teas go farther in consumption, or are cheaper in use, and are much more tasty than the China teas of an ordinary description. Russia, America, and Australia still consume China teas to the exclusion of other teas*; but this preference is due to an unfa-

miliarity with those other teas which may not last long. Ceylon tea is being pushed in Australia and New Zealand; and the Chicago Exhibition will offer an excellent opportunity for pushing both India and Ceylon teas in the United States. In England tea from Ceylon was regarded as a curiosity only half-a-dozen years ago; but now it is sold and puffed by every grocer, and there is scarcely a railway station, or hotel which is not adorned with an ornamental poster, or card, setting forth the virtues of some special tea from the spicy island. The growth from small beginnings of the India tea trade seemed marvellous, but it is put in the shade by the rate of expansion of the tea trade of Ceylon: By all accounts the island has by no means reached the maximum of its productive power; and it seems probable that, having succeeded in passing its China rival in the British market, it will at an early date run its India rival very close for pre-eminence. The Chinese will not be slow to consume the tea grown in their Empire for which the outside world makes no offer; but there is comparatively very little home consumption of tea in India and Ceylon. The native in this part of the world has yet to acquire a taste for tea; but when he does acquire it, or when such taste, or appetite, is as general in India and Ceylon as it is in China, there may be small difficulty in meeting the local demand that will arise, and in satisfying also the increasing requirements of the world at large.—*E. Mail*.

SEEDING OF THE BAMBOO.

The hardier species of Bamboo are becoming deservedly more popular year by year for the adornment of English pleasure-grounds. One thing, however, seems not unlikely to be lost sight of by many, viz., the fact that the culms of the Bamboo flower but once, the plant perishing immediately after the ripening of the seed. The usefulness of the many species of Bamboo now introduced into England in the embellishment of our gardens cannot be questioned, at the same time there is yet to be considered the eventuality of the flowering, seeding, and consequent death of the plants—which no art of the gardener can stay—after they have reached the climax of their grace and beauty. It would be, I imagine, almost impossible to determine the age at which these hardy Bamboos will produce flowers when grown in this country; most probably the term of years will differ with the various species.

With regard to the great Bamboo of tropical India, *Bambusa arundinacea*, it is a well ascertained fact, that the coming to maturity of this gigantic grass only occurs after a growth of some fifty years' duration; and as the phenomenon of its flowering, seeding, and subsequent death in India and other climes—where it covers with its huge and picturesque clumps many square miles of country—can have been seen but by few Englishmen of the present generation, some account of the extraordinary spectacle by an eye-witness may prove of some little interest to the readers of this journal.

It is unnecessary, of course, to give any lengthy description of the plant; suffice it to say, that in the locality in India where I had the rare fortune of witnessing the flowering and seeding of this gigantic member of the grass family on a large scale, the culms frequently attain a height of from 60 to 70 feet, and a diameter at their thickest part of from 8 to 10 inches. These culms are furnished with lateral branches, throughout their whole length adorned with a profusion of light green leaves. The plant is deciduous, shedding its leaves in India during the dry season, which are again renewed on the approach of the spring showers. The clumps present the appearance of colossal plumes of feathers, and when seen in full leaf are beautiful beyond description.

The soil of the tracts of country the Bamboo affects in South India is mostly of a shallow nature, with a gritty, ferruginous subsoil, and it is not found where the rainfall is excessive. When the clumps are in full vigour, the culms are produced of the above dimensions with amazing rapidity.

* Not now correct of Australia.—Ed. T. A.

It was during the years 1863-64, while engaged in Coffee planting in the district of Wynaad, in the province of Malabar, that I witnessed the phenomenon of the seeding of *Bambusa arundinacea*. The plantation I had charge of at the time was situated in the midst of an extensive Bamboo jungle within but a short distance of the frontier of Mysore, and on the main road from the Malabar coast to Seringapatam and Bangalore. At the time of my arrival in the district, the magnificent Bamboo forest, interspersed with such deciduous hard-wooded trees as Teak, Kino, Rose, and Sandal woods, and others of an equally valuable description, was, although unknown to me at the time, upon the eve of a sudden and wonderful transformation. Hundreds of square miles thickly covered with the exquisitely graceful clumps of the Bamboo, giving to the landscape as far as the eye could reach a beauty difficult to describe, were to be changed in the brief period of a little over a year by fire into a charred and blackened wilderness, the myriads of nodding plumes that for half a century had graced the woodlands were, at the call of Nature to blossom, yield their seed, and disappear from the face of the earth as by the breath of a destroying angel.

The south-west monsoon rains of 1863 had ceased about the middle of September, leaving the jungle tracts of Malabar in the very heyday of their glorious greenery, the Bamboo plumes waving to and fro by the gentle breezes still prevailing from the westward, glistening in the light of a tropical sun, and, as yet, showing no trace of the change they were so soon to undergo. As the season advanced, hot parching winds from the east began to take the place of the mere kindly breezes from the west, and by Christmas, the leaves of the Bamboo thickly covered the ground. Simultaneously with the disappearance of the leaves from the laterals, the inflorescence began to appear, and the aspect of the country in every direction changed as if by magic. No one was prepared for such an eventuality, and the English planters in the district were struck with something akin to alarm when the fact dawned upon them that, in the course of a very brief period, not a living Bamboo would be left in the forest. A few there were who refused to believe that the culms would perish after ripening their seeds, and were only persuaded by the actual realisation of the fact. As nearly as I can remember, the seed was matured by the middle of May, the panicles of grain weighing down the culms to a third of their length, and giving them withal a graceful as well as fruitful appearance. When the seed, which was about the size and had much the appearance of small Oats, had fully matured, it fell to the ground in showers by every passing breeze, and then came a happy season for both man and bird. Sea-fowl, spur-fowl, partridge, jungle-fowl, and quail, with which the jungles abounded, revelled in, and got fat upon, the plentiful supply of good food so suddenly bestowed upon them by the hand of Nature, and man himself was not slow to take advantage of the offering. The coolies from Mysore employed on the Coffee plantations could with difficulty be induced to remain steadily at work during this Bamboo harvest, and the jungle tribes could not be persuaded to work at all, but subsisted solely on the fallen grain of the Bamboo, so long as any could be gathered from the ground. This seed they appeared to highly value, and, judging from appearances, it seemed to be very nutritious. The grain was ground into meal by the aid of small hand-mills, and two modes were employed in its cooking—the one by baking in the form of cakes, and the other in boiling it into a kind of thick porridge. I myself ate the cakes on several occasions, and found them fairly palatable. These jungle tribes, although perfectly aware of the value of the vast granary thus laid at their feet, were, notwithstanding, improvident to a degree. They ate abundantly of the fruit whilst it lay on the ground, but made no provision against the approaching destruction of the whole by jungles fires. So, after these had licked the ground, they had, perforce, to return to work on the Coffee plantations. At the height of the dry season, and when the

earth was thickly covered with a coating of Bamboo leaves and seed, these fires began to do their work, and, apparently, so completely that it was hard to believe that a single Bamboo seed could have escaped destruction, and that in the course of a decade or so, another such magnificent Bamboo forest could be produced; but Nature, in some mysterious way, was equal to the occasion, and before I left India in 1877, the Bamboo zone of Malabar and Mysore was clothed with another jungle, consisting of clumps approaching in size and grandeur those that perished in 1863.

From the date of the seeding of the Bamboo, the clumps stood throughout the following monsoon leafless and dead, but intact; and it was not till nearly a year after that their complete destruction by fire began. When the dead and sapless clumps caught light, the whole country was filled with flame and smoke for weeks together; loud reports were heard night and day without intermission, resulting from the pent-up gases within the hollow culms, and the whole Bamboo zone so picturesque and beautiful but a twelvemonth before was quickly reduced to a scene of desolation. The total destruction of the clumps, however, was not accomplished in one season, many escaping the fires till the second, and some till the third.

The young seedlings soon began to appear, but made but slow progress for several years. As time went on, the annual growth of culms waxed stouter and stouter, till at last a thick undergrowth of low Bamboo tufts covered the ground, which, in the fulness of time began to send up gigantic canes, till the forest was restored to its former strength and beauty.

With reference to the period of time required for the maturation of *Bambusa arundinacea*, I was at some little trouble, while in India, to ascertain from the native tribes inhabiting the jungles of the district the approximate duration of its existence, and was told by several men, apparently about sixty years of age, living widely apart, that they remembered a similar phenomenon of the seeding of the whole of the Bamboos of the district when they were boys. From this I concluded that about fifty years was the limit to the life of this giant species of *Bambusa*.

About three months before the flowering of the Bamboo, I had occasion to clear some 30 or 40 acres of land for the purpose of Coffee planting, the culms of the Bamboo being cut close to the ground. I waited patiently, curious to know the result of such an operation. When the monsoon rains began, the huge stools left in the ground began at once to send up numerous small culms of from 8 to 10 feet in height, and furnished with laterals. On the cessation of the rains these immediately flowered and seeded, after which the old stools perished absolutely, so that the act of cutting down the original culms had only the effect of delaying, not frustrating, Nature in her efforts at reproduction.—*J. Lowrie.*

—*Gardeners' Chronicle.*
[The flowering must take place at shorter intervals than fifty years, for we found the bamboos in South Wynaad, flowering, seeding and dying in 1877. We suspect much depends on seasonal influences. 1887 was a year of famine from drought.—*Ed. T. A.]*

THE STORY of a coffee-plant as told by Dr. Kerr Cross possesses quite a romantic interest. Some ten years ago the authorities of Kew Gardens sent out a number of slips of the coffee-plant to Blantyre, in Central Africa. Only one survived the journey. This slip grew, bore seed proved itself wonderfully productive, and is now the progenitor of a million of plants growing on one estate alone, besides hundreds of thousands of others in that region. In three years the plants give a return. The quantity is also good, as shown by the fact that Shire coffee has recently been fetching wholesale 112s. a hundredweight in the London market.—*M. Mail*, Nov. 25th.

THE REAL POSITION OF THE NATIVE
CULTIVATOR AND THE MEANS
WHEREBY HE CAN IMPROVE IT.

(Communicated.)

The utterances of His Excellency the Governor, and the other speakers who addressed the meeting on Saturday evening (Nov. 28th) at the School of Agriculture, will show to the Ceylonese the deep interest taken by them in the future welfare of the nation as agriculturist, or cultivators of the soil. There is no blinking at the fact that the Ceylon of today is to the Sinhalese cultivator, the Ceylon of 70 years ago. For while commerce has increased and the planting enterprise of the British capitalist has progressed with leaps and bounds, the Sinhalese agriculturist has remained the veritable Rip Van Winkle of the country, to find himself sleeping over decades of progress, which came not to him in the land of his birth. His family has increased in numbers, but the area of his cultivation has remained much the same in extent. Lands available for asweddingizing is of limited extent in the populated villages, and this work itself involves much labour and expense which he cannot readily afford; and the consequence is that the limits of subsistence have been pressed against for some time past now, in different parts of the island in a manner that admits of no further doubt or speculation as to the cause of the widespread distress and despondency that prevails in the country. The next class that threatens to overrun the country without finding adequate employment to maintain themselves, is from among the so-called educated section of the community. Schools, both Government and private, swarm with children of educated and uneducated Sinhalese parents, and the numbers keep increasing with the growing desire for knowledge as a means wherewith to attain an end. The chief end being—after making every allowance for valuing knowledge for its own sake—the purchase of a moal. But out of the thousand who by reason of their scholastic and literary attainments at school and college are found knocking at the doors of Government offices for the privilege of filling a vacancy at R20 a month in exchange for services that are worth R100 in other countries, only the smallest percentage may hope to enter. So at the merchants' offices, so also at the lawyers' offices. What is to become of the rest of this educated class who from their very training are led to live a life rather of hope and expectancy, than of usefulness in the field of manual labours with their brethren, till distress overtakes. The butler or the cook who earns his R20 is better off by far than the educated clerk at R20 a month with his increased artificial wants and cultivated tastes; and disappointment and despair, poverty and its concomitants overtake him, and hold him with firmer grip than the less educated, less favored play-fellow of his childhood from an agricultural population large numbers have passed on to a wage earning section—seeking such services, menial and laborious, as were open to them to enter; while the ranks of the artificers and tradesmen have been glutted to the last limit of profitable labours and investment, leaving still a large and constantly increasing balance or surplus population in the villages and in the towns for whom there is literally no work to do. There are many acres round about his fields and available forest land still in Ceylon for the Sinhalese cultivator if he will avail himself as the British planters have done. But the Sinhalese agriculturist has not been taught the art of cultivation as yet to see it as the China man, the Indian, or even the Jaffna Tamil in Ceylon sees it. Beyond Chena cultivation, in the most primitive manner, even as nomadic races adept it. The vast bulk of Sinhalese cultivators do not care to

venture. The fact that these villagers has often a small garden with palms and jak trees, does not bear on the question materially as it does not provide him and his family with any thing like what his needs demand. But that he does not extend this garden by adding to it year after year, acre after acre is what is ground for just complaint and regret. It is to this class of the population that the pupils going out of the School of Agriculture will carry their apostolic missions. To those who have lived long enough in the island to watch the progress and the poverty of the country growing side by side, it must be painfully clear. That to many—and that a large majority—education and misery have grown as bud and blossom out of the same stem. It may seem rank heresy to some of your readers to hear such an assertion confidently put forward. But there is no denying that the Sinhalese boy has unconsciously and gradually been wearied from the traditions of his ancestors by the glowing prospects of wealth, influence and prosperity, that shines on his horizon in the early morning of his life as he turned his back upon his peaceful village and smiling corn-field to be initiated into the mysteries of English grammar.

The Australian Colonist educated or uneducated sees the necessity for manual labour in the gardens where he grows fruit for home and foreign consumption, as the first occupation for the colonist. Jamaica, as may be gathered from the paper contributed to a periodical this year by one of its ablest Governors, is reviving under the invigorating influence of its fruit trade. Singapore and the islands of the Malayan archipelago are busy with the cultivation of nutmeg, pepper, cloves and other tropical products. But the Ceylon of the Sinhalese is in this respect even under the blessings of British rule today what it was at the capitulation three quarters of a century ago.

AGRICULTURIST.

SCIENTIFIC GOSSIP.

Dr. Langenbeck has critically scrutinised the evidence that has been adduced during the last three years in the controversy between the supporters of Darwin's theory of the formation of coral reefs on areas of subsidence and the advocates of Dr. Murray's rival theory of their formation on areas of elevation, and he arrives at the conclusion that Darwin's theory holds its own as a general explanation, and is the only one that is applicable to the phenomena presented by a large class of well known reefs. It may be added that it is the theory which alone can account for the vast thicknesses of coral strata met with in geological formations. It is evident that when coral grows on an area which is undergoing elevation, the coral stratum must be thin and patchy, while coral which is formed on subsiding foundation, and continues to grow while the subsidence is going on may attain a very great thickness, limited only by the time and vertical extent of the depression. When there is neither subsidence nor elevation, the reef may extend laterally till the depth becomes too great, but cannot become thicker. Of course, coral will grow wherever the proper depth of water and the supply of food are favorable to the life of the coral insect, but this life is most quickly checked on the rising areas, while there will be a rapid growth and accumulation on the areas of subsidence only. Dr. Murray's theory was first brought into prominence by the notice taken of it by the Duke of Argyll, whose fixed faith is that Darwin must invariably be wrong, and that, consequently those who differ from him must be right. There is, no doubt, some obstinacy and delusion on the other side, but hardly to such an extent.—"Eclipus" in *Melbourne Leader*.

[The interesting question of the distance down from the surface at which the polyparia can live and work requires to be settled.—Ed, T. A.]

POULTRY SCRATCHINGS.

Use plenty of white wash in your chicken houses. Green food is needed for young and old chickens. A dust bath with a little carbolic powder mixed is a sure remedy for lice.

Charcoal, oystershell, bonemeal and gravel should be kept within reach of your fowls.

Do not expect that more than three-fourths of all your chicks will live to maturity.

Young turkeys have to be kept out of damp quarters; old turkeys will stand anything.

Try and set your hens so as to have two hatch out at the same time, and give the broods to one hen. Good care, under all circumstances and at all times, is a prime necessity to success in breeding fowls.

Care must be taken that chickens are not brooded on cold, damp ground, and the bed, whatever it be, must be renewed when soiled.

There is no one thing which conduces more to cleanliness and healthfulness in poultry breeding than a liberal and judicious application of whitewash on the in and outside of the poultry house.

Farmers, invest a few dollars in pure bred fowls for the benefit of your boys if they have a fancy in that direction. A boy needs something that he can call his own. Don't compel your son to lead an altogether humdrum life. You were once a boy yourself.—*Rural Californian*.

HINTS ON WATERING PLANTS.

A report of the Ohio Experiment Station contains the following:—

Rain water is better than spring or well water. Hard water may be greatly improved by adding a drop or two of hart-shorn or a little soda—a small nugget about the size of a pea, to every gallon of water used.

Time.—Morning is best, next, the evening. Never water house plants when the sun is shining brightly upon them.

The supply of water must be regulated according to the demand of the plant.

The condition of the plant and of the surface soil is the best guide.

Never give water when the soil is moist to the touch.

Nearly all plants require more water when in bloom than at any other time; they require more in a warm temperature than in a cold; more when in a state of active growth than when at rest.

Plants in open rooms usually require water once a day and some that delight in moisture, need it twice.

All plants should be examined at least once a day with intent to water, if that is necessary. Experience alone determine the proper amount to give each plant.

Cleanliness.—The leaves of plants should be kept free from dust, hence frequent washings are absolutely essential.

Never wet the flowers of a plant, nor allow drops of water to stand on the leaves in the sunshine.

Never allow water to stand in the saucers of the pots unless the plants are semi-aquatic.—*Florida Dispatch*.

WHERE THEY CAME FROM.

"Lemons were used by the Romans to keep moths from their garments, and in the time of Pliny they were considered an excellent poison. They are natives of Asia. Spinach is a Peruvian plant. Horseradish is a native of England. Melons found originally in Asia. Fibberts originally came from Greece. Quinces came originally from Corinth. The turnip is a native of Rome. The peach originally came from Persia. Sage is a native of the south of Europe. Sweet marjoram is a native of Portugal. The bean is said to have a native of Egypt. Damson originally came from Damascus. The nasturtium came originally from Peru. The pea is a native of the south of Europe. Ginger is a native of the East and West Indies. Coriander seed came from the East. The cucumber was originally a tropical vegetable. The

gooseberry is indigenous to Great Britain. Apricots are indigenous to the plains of America. Pears were originally brought from the East by the Romans. Capers originally grew wild in Greece and Northern Africa. The walnut is a native of Persia, the Caucasus, and China. The clove is a native of the Malacca Islands, as is also the nutmeg. Vinegar is derived from two French words, *vin* aigre, sour wine. Cherries were known in Asia as far back as the seventeenth century. Garlic came to us first from Sicily and the shores of the Mediterranean. Asparagus was originally a wild sea coast plant and is a native of Great Britain. Nectarine received its native name from nectar, the principal drink of the gods. The tomato is a native of South America, and it takes its name from a Portuguese word. Greengage is called after the Gage family, who first took it into England from a monastery in Paris. Parsley is said to have come from Egypt, and mythology tells us it was used to adorn the head of Hercules. Apples were originally brought from the East by the Romans. The crab apple is indigenous to Great Britain: It is a curious fact that while the names of our animals are of Saxon origin, Norman names are given to the flesh they yield. The onion was almost an object of worship with the Egyptians 2,000 years before the Christian era. It first came from India. The cantaloupe is a native of America, and so called from the name of a place near Rome, where it was first cultivated in Europe. Before the middle of the seventeenth century tea was not used in England, and was entirely unknown to the Greeks. The word biscuit is French for "twice baked," because originally that was the mode of entirely depriving it of moisture.—*Florida Agriculturist*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Nov. 7th.

CINCHONA.—A supply of more than average extent had been demanded for sale at Tuesday's auctions, but at the last moment about 500 packages of East Indian and Ceylon bark were withdrawn, in consequence, it is believed, of the death of one of the owners and the transference of his interests to trustees. The quantity offered for sale was, therefore, as follows:—

	Pkgs.	Pkgs.
Ceylon	1,311	of which 1,206 were sold
East Indian	433	do 427 do
Java	33	do 33 do
South American	238	do 233 do

Total 2,020 do 1,904 do

The quality of the bark calls for no particular comment—there were no very fine parcels, but the average of the assortment appeared to be a pretty high one. Root bark was offered more plentifully than usual—one Ceylon plantation alone contributing about 12 tons of *succubra* root. Competition was fully active throughout the auctions, and nearly the whole of the supply was taken at prices quite equal to those of the preceding auctions. The nut may be placed at 1-16ths d. to 1½d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lbs.
Agents for the Mannheim and Amsterdam works	209,831
Agents for the Italian and American works	63,615
Agents for the Brunswick factory	63,284
Agents for the Frankfurt O/M. and Stuttgart works	47,591
Messrs. Howards & Sons	32,046
Various manufacturers' agents	14,491
Sundry druggists	42,905

Total quantity of bark sold

.....	473,788
Bought in	29,911

Total quantity of bark offered

.....	503,709
-------	---------

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots and *vice versa*.

ESSENTIAL OILS.—Oil of Citronella offers on the spot at 11-16ths d. per oz. for tins. To arrive there is no business doing.

NATIVE AGRICULTURE IN CEYLON.

"Agriclturist," whose communication appear elsewhere, is too pessimistic. Native agriculture has advanced in area and to some extent improved in modes of tillage and amount of yield since the capitulation and the days of the Madras Civilians and Governor North. The picture drawn by the latter of the scantiness of rice grown in the island in his day was far more marked by Rembrandt-like shadow than the scene depicted by Governor Havelock. Most of the people, however, have never heard of Malthus as a philosopher or of thrift as a virtue; and it is too true that in many parts of the island population is out-growing the means of subsistence. The remedy is either extended cultivation of the land, or improved and intensive cultivation of the portions already brought under the plough or the mamoty.

Let us have extended rice cultivation by all means, but more important still is the duty, which ought to be, we were going to say compulsorily pressed on the people, of so cultivating the lands already under crops, as to increase the yield manifold beyond what is now harvested. The experiments to which Mr. Green alluded and those recorded in Mr. Driebert's comprehensive report show the vast room there is for possible improvement and the extent to which improved methods when adopted are rewarded. If we felt as Governor Havelock seemed from the tone of his utterances to feel, that poor returns from rice culture are the rule, and that such inadequate returns are due, not to the ignorance and carelessness of the cultivators but to natural causes which can be neither controlled nor overcome, of course we should feel as much the necessity of abolishing the paddy tax as His Excellency does. But in view of what was stated in the Hall of the Agricultural College, apart from the opinions of experienced servants of Government and others, previously expressed, we hold that the duty of Government is to retain the tax, using a large proportion of it to encourage not only improved and extended rice culture but the growth of other cereals and food products in the shape of root plants and fruit trees. We are especially glad to notice that the attention of the Principal and pupils of the Agricultural College is specially directed to such leguminous plants as dal and horse gram. The crops from such plants are far richer in nutritive properties than rice is, and the long-voxed question of leguminous plants deriving a large portion of their nitrogen from the air seems to have been settled in the affirmative. Lawes and Gilbert being converts to that proposition. To legumes ought to be added a larger cultivation of Indian corn than at present—the "mealies," to use the Cape Dutch term, for what formed the staple cereal of the colony whenoe Sir Arthur Havelock came to Ceylon. If the natives so used their cattle as to get plentiful supplies of butter as well as milk, the boiled beads of Indian corn, seasoned with butter, would constitute a delicious as well as a nutritive diet. Indian corn, like all other similar products, requires occasional applications of fertilizing matter, and one of the chief duties of the missionaries from the Agricultural College must be to teach the people the value, when collected and properly composted, of refuse matter which, when neglected, becomes not only offensive but injurious and dangerous to life and health." "Agriclturist" draws a gloomy picture of the condition of large numbers of Sinhalese educated to look down on honest labour. But edu-

cation properly conducted, as it is at the Agricultural School, ought ever to recognize the dignity of labour; and knowledge ought not to be a hindrance but a help to the conscientious and industrious tiller of the soil, who ought to feel proud of "eating bread in the sweat of his face." We were specially interested in that portion of Mr. Driebert's report which indicated that a Sinhalese gentleman who had received a training at the Colleges had been successful in raising the tuber known as the common or Irish potato—not to be confounded with the sweet potato, which latter has been so naturalized in Ceylon as to be often regarded as indigenous. Both these valuable roots are really of American origin, and an abundant cultivation of both would largely alleviate that pressure of population on the means of existence which "Agriclturist" truly states is becoming a serious problem. We have alluded to the breeding of cattle and horses,—ponies, such as those for which Java is famous, would be specially useful,—and we have attracted attention to the necessity of increasing our food supplies in the shape of good and wholesome freshwater fish. This question, curiously enough, is an agricultural one. The water of irrigation in Ceylon is plentifully peopled by fish, but we want superior varieties such as the large golden carp of Java in which island, as our late friend Mr. Moens told us, the cultivators gather two harvests, of almost equal value: first the paddy crop and then the teeming wealth of fish. The fewer goats in a country the better; they are the inveterate destroyers of all vegetation. But could we not in regions of the lowcountry too dry for the existence of the land leech, and in our mountains at altitudes too high for the leech pests, breed sheep superior to the long-legged, goat-like creatures which in Jaffna are mainly valuable for manuring tobacco and vegetable fields? And the mention of Jaffna reminds us that great benefit to the Sinhalese would result, were they in many places to imitate the careful and productive well-cultivation for which the northern Peninsula is distinguished.

HERE is an Italian recipe (1659) for making Tea. "Take a pint of water and make it boily then put in it two pinches of Tea, and immediatel; remove it from the fire, for the Tea must not boil; you let it rest and infuso time enough to say two or three paters ('l'espace de deux ou trois pater'), and then serve it with powdered sugar on a porcelain dish; so that each one may sugar to his taste.—*Madras Times*."

In view of the "boom" that there has been in Ceylon Tea of late, it is a little strange to hear that even one tea planter thinks of deserting that island to try his luck in another part of the world. We are informed that a gentleman from Ceylon was in California last month, with a view of embarking in the Tea planting industry on the Pacific coast. He believes the climate and soil favourable for the growth of the plant. He is indeed more sanguine than some section of the American Press. A contemporary on the Pacific coast, says:—"Considering the cheapness of labour employed in this industry in China, Japan, and Ceylon, even if natural conditions on this coast are favourable, it is difficult to see where the hands are to be found willing to work in California Tea plantations for wages anywhere near as low as those paid abroad. Chinese and Japanese labourers are out of the question, and no white man has yet been found in California who will willingly work for less than \$150 per day." And a New York trade paper endorses this with the remark:—"It has been demonstrated that the Tea plant will thrive in the Southern States, but owing to the expensiveness of labour Tea growing cannot be made a profitable industry.—*Madras Times*."

THE AMSTERDAM CINCHONA AUCTIONS.

(Telegram from Our Correspondent.)

AMSTERDAM, Thoraday Evening.

At today's cinchona auction 3,691 packages of bark were sold at an average unit of 6 cents (=11-16d per lb.), showing a barely steady market. Manufacturers' barks in quills, broken quills, and chips sold at 11 to 56 cents (= 2d to 01d. per lb.) ditto root at 16 to 46 cents (2½d to 8½d per lb.). Druggists' barks in quills, broken quills, and chips brought from 13 to 135 cents (=2½d to 2s per lb.), and ditto root 11 to 16 cents (=2d to 2½d per lb.) The principal buyers were the Anerbach factory, Messrs. C. L. Schepp & Zoon, of Rotterdam, the Brunswick Works, and the Amsterdam Works.—*Chemist and Druggist*, Nov. 14th.

THE INDIAN TEA COMMUNITY.

To the Editor of the *Home and Colonial Mail*.

Sir,—While it can hardly, of course, be said that the Indian tea industry is, at the present time, altogether in a bad way; yet, looking to the competition of Ceylon and to the great increase in the production in India itself, there is no doubt that the situation is such as to give rise to some anxiety as regards the immediate future.

Taking current Mincing Lane prices, as represented by the sales of the principal well-known London companies' marks, and comparing them with the averages realised for these companies' entire crops in 1890, I am driven to the conclusion that many of them are at present obtaining much lower prices, and that, in the case of some, it is questionable whether the price of the produce is much in excess of the actual cost of production. In order to bring this home, attention may, with advantage, be drawn to the following comparison of current prices with those ruling during the last three years, taken from Messrs. Gow, Wilson, and Stanton's weekly circular:—

	1888.	1889.	1890.	1891.	Total
Pekoe Soehong	7½d	6½d	8d	5½d	2½d
Common Pekoe	8½d	8½d	8½d	6½d	2d
Medium Pekoe	9½d	10d	9½d	8½d	1½d

What is, then, the attitude which the tea community is prepared to take up in the light of this rather painful conclusion? This is a serious and an important question.

It is undoubtedly a satisfactory feature of recent years that there has been an increasing tendency on the part of tea producers to draw together and combine for their own mutual protection, and in various directions evidence is not wanting of the desire for such mutual support, which only requires some stirring up to ensure its manifestation. It, however, the great industry is to progress, and if it is to continue to be profitable to its members, much more than has hitherto been done must in the future be done to ensure this. The spirit of "No man for a Party, but all men for the Cause," must be much more strongly evoked. There must be more working together, more of the "shoulder to shoulder" which has won Britons their battles, alike in war and in peaceful competition.

This point can but be urged upon your numerous readers, and those who have been backward must be urged to come forward now; better late than never. There are many schemes at present on the tapis for extending consumption and improving the prospects of the tea grower, and it will not be difficult for your readers to inform themselves of what these are. Let them enquire diligently, and then give their support willingly and liberally. One-tenth of 1 per cent of the capital invested Indian tea would furnish a fund of well-nigh £10,000.

As has been frequently pointed out in your columns, the industry already possesses an organization both in London and in Calcutta, whose object is to further the best interests of the planting community; and as component parts of the organization we have "good men and true," men who

"mean business," and have the cause—their own cause and that of their brethren—a heart. These organizations, however, and the master spirits who work for the cause—let it be said with regret—do not always receive that cordial support and backing which is due them. It cannot be too strongly urged that all—that every man who has any, however small an interest in Indian planting, should enrol themselves in the ranks of one or other of the tea associations, and not only enrol themselves and pay their guinea subscription, but that they should work as one man, in every direction, to strengthen the organisation and increase the influence of these bodies and thereby help, if nothing else, to fill their own pockets fuller than would otherwise be the case. After all, I am merely appealing to self-interest, and lowest stimulus.

The world's consumption of tea must be increased if we are to continue to draw profit from our planting enterprise, and to effect this at all rapidly is a difficult matter and can only be done by combination and by push. Indian tea must be promulgated and its merits more widely preached, and money must be spent and "bread thrown broadcast on the waters," so that it may come to shore in future days.—Yours truly,

London, Nov. 11th, 1891.

OBSERVER.

"WICKED" TEA.

In the *Illustrated London News* of Nov. 7th, in the Ladies' Column, Mrs. Fenwick-Miller writes:—

Tea, that precious refuge of the nineteenth-century woman, has been much talked of lately. Here, as in the case of a lady's reputation, to be "talked of" means to be abused. One critic declares that it is no longer women who are the worst tea-drunkards; that the University undergraduate has now far surpassed the weakness of the other sex. "Wicked" tea is Sir Andrew Clark's description of the liquor as it is frequently offered. He is complaining of the tea commonly dispensed as a beverage by ladies in the afternoon, which is allowed to stand in the teapot for half an hour after being made, and warmed up for new-comers by pouring a flood of hot water on the over-drawn leaves. This is "wicked" tea. That which is physiologically righteous, according to the learned physician, must have stood only five minutes after being made: it should be originally black China tea—not Indian—and the old-fashioned allowance of one spoonful for each consumer and one over for "the pot" is the right quantity. Finally, a lady's article in a magazine declares that women "degrade themselves" by their out-of-door lunches, which usually consist of tea and buns; she avers that this habit of lurching on tea, so long as it be continued, will keep women feeble, nervous, and comparatively useless creatures.

These complaints, all appearing in the world of periodical literature, but in very diverse quarters, at one moment, may be taken as an illustration of the cycle of ideas. If we observe, we shall find that notions reappear at regular intervals, like comets. All this about tea has been said before; but, for all that, it is just as well to have our minds impressed now and again with the degree of truth that the lucubrations contain.

Stidious men are, and always have been, quite as great consumers of tea as women, and for the best of all reasons—that there is not any beverage so stimulating to the nerves with so little necessary evil attendant on the stimulation. The evil of a stimulant may be measured by, first its temporary, and next its permanent, results on the constitution. Those which produce depression corresponding to or deeper than the stimulation they produce, and those which after a time injure the structure of the bodily organs, are dangerous. Now, tea can challenge the world of stimulants on both grounds. The great authority on food, Dr. E. Smith, says, "Tea promotes all vital actions"; Dr. Parkes, the standard writer on hygiene, avers, "Tea seems to have a decidedly stimulative and restorative action on the nervous system, and no depression follows"; while the great chemist Liebig

found that tea aided the assimilation of food, and made it "go further." I call that a comforting little list of scientific authorities to back us up in the consumption of our precious "fif o'clocker," as the French fashionable world calls the afternoon meal that it has adopted from the English. I am afraid that I for one should go on taking tea if all the savants abused it; but still it is comfortable to be encouraged with scientific approbation in doing as one likes.

Something we must have when we are deprived by any circumstances of the great natural stimuli, plenty of open-air exercise and long sound slumbers. These natural boons are not to be commanded by students sitting close to work, by women engaged in sedentary employments, or by a large number of housewives, whose fingers must always be busy and whose brains must be, early and late, paying tax to family responsibility. Such classes positively have need of some stimulant to prevent their nerves getting exhausted and their faculties sluggish. Is there anything better than tea?

Certainly not. Alcohol is a thousand times worse, more disastrous to the body, more perilous to the mind. The tribe of narcotics, which have the dangerous peculiarity of stimulating in small doses and soothing in larger ones, are rapidly fatal to the health and energies of those who fall under their control. Even comparatively mild drugs do this, as well as opium and morphia. The nurses in a certain London hospital recently contracted a habit of taking antipyrin as a "pick-me-up," with results that need not be detailed beyond saying that they were quite deplorable. In fine, no beverage has yet been discovered that is for one moment comparable in the combination of efficiency as a stimulant and innocuousness with that so dear to the Englishwoman and the man of highly developed nerves—tea. [Hear! hear!—Ed. T. A.]

But judiciousness is required in its use, of course. The tannin which is drawn out by prolonged infusion tends to cause indigestion; and the too-frequent or violent application of even this mild stimulation to the nervous system makes it over-excited and unstable. There is great truth in what Sir A. Clark says about the wicked tea of many afternoon "At Homes." Tea which has been nursed under a cosy for half an hour* is like corked wine or tarotid fish—it was good once, but it has "gone off," to be disgusting and injurious. The only plan that a hostess can pursue to avoid at one time waste of tea and bad liquor is to have the tea poured off the leaves ten minutes after it is made.† I venture to say ten in place of Sir A. Clark's five, because London water is hard and draws slowly. The liquid can be kept hot afterwards in any way most convenient. It may even be left in a jug on the kitchen stove without doing it any damage. It is the continuous drawing of the leaves, not the standing in heat of the completed infusion, that is mischievous. The tea being made, therefore, in the proportion of one large teaspoonful of the dried leaves to each half pint of boiling water—not over-boiled but fully at boiling point—should be allowed to stand for ten minutes, and then the infusion should be poured off into a big teapot that can be kept under a cosy, or put into a silver urn with a little spirit-lamp burning underneath, not high enough to boil the tea, but just so as to keep it hot.

TEA IN THE UNITED STATES

Is thus noticed without a word about the essential element of cheap labour:—

A correspondent of the *American Garden*, Mr. W. F. Massey, writing from Charleston, S. C., gives some very interesting information about domestic tea culture. He says: "We were very much interested in visiting Dr. Shepard's tea gardens at Summer-ville, twenty-two miles from Charleston. Here Gen. Le Duc, when Commissioner of Agriculture, began some experiments in tea culture, which his short term of office left no time to complete and which his successor abandoned. Dr. Shepard has

bought the old Government plantation, and has planted a large additional area. The old trees planted by the Agricultural Department have been given over to seed bearing, and new nurseries are being started from these and from imported seed. The new tea gardens are all planted with the Assam hybrid tea, but the doctor has orders abroad for seed of all the best sorts from China, Japan and the Himalaya region. His tea has been pronounced very superior by experts. The well-cultivated gardens and the thrifty plant is perfectly at home there. "That a high quality of tea can be easily made in North and South Carolina seems evident. Before going to South Carolina we visited a plantation of tea made over thirty years ago near Fayetteville, North Carolina. We found the tea bushes struggling for existence in a thicket of pine, laurel, cherry, and all manner of wild growth. It has had no culture whatever since the war, and yet from these trees the old lady who owned them gave me a large bundle of tea of remarkably fine quality, which a New York dealer who tested it at the hotel pronounced worth \$1 per pound at wholesale. The ridicule with which the Northern press treated Gen. Le Duc's experiments caused the abandonment of systematic effort in this direction, but it does look as though a new money crop of great value might be added to the South, and I am glad to record the fact that Dr. Shepard is giving the matter a thorough test. I hope his work may be crowned with successful results."

NOTES ON PRODUCE AND FINANCE.

THE IMPORT OF TEA IN OCTOBER.—The Board of Trade Returns for October show that the imports of tea reached the high total of 30,485,170 lb.—about the biggest total ever recorded in one month. India sent 18,263,000 lb., Ceylon 5,651,000 lb., and China, &c., 6,569,000 lb. The greatest proportional increase is of Ceylon, the receipts being more than double those of October, 1890.

LAST WEEK'S SALES.—The *Grocer* says of Indian tea:—"The deliveries continue to progress favourably, and last month equalled 10,520,450 lb., in contrast with 9,822,000 lb. in the former year, but as the imports were uncommonly heavy, stretching to 16,094,850 lb., against 15,236,900 lb. in October, 1890, the stock was further increased to 31,534,200 lb., and at the end of the month presented a comparative excess of 5,477,000 lb. The public sales since our last summary have offered about 42,900 packages Indian tea, which have had to be disposed of, as the saying is, 'by hook or by crook'; and a very trying period it has been for the tasters and valuers, who have had at least two days' hard work to do in the same time usually allowed for only one. This is the third week in succession that the auctions have aggregated over 40,000 packages as the supply to be immediately dealt with by the wholesale dealers, and no wonder that their energies begin to flag. The biddings have lacked sharpness and decisiveness in many cases and been positively spiritless in others, so that several invoices have had to be wholly withdrawn, and where sales have been completed prices have ruled irregularly and lower. The common to fair grades below 9d and 1s, which preponderate largely in the general supplies, have been, as hitherto, most out of favour, and must be considered ½d to ¼d per lb cheaper, or even 1d under the rates secured a month or six weeks ago; but prices for the medium kinds, though here and there weaker, have shown more uniform steadiness, and the finer qualities, being far from plentiful as they might be, have realised relatively firm rates. The landings of Ceylon tea last month amounted to 4,596,600 lb. The *Produce Markets Review* says:—"The demand for Indian tea is well maintained, but at the later sales the common grades sold at irregular, but, on the whole, at rather easier prices. These descriptions have been largely represented at recent auctions, and, as many of the teas are very inferior, it is not surprising that their value shows a drooping tendency. The demand for low-priced teas is also less active than

* Over the leaves.—Ed. T. A.

† Five to seven minutes still better, in most cases.—Ed. T. A.

it was some time ago, the consumption evidently shaping towards better quality than hitherto. The quantity of Ceylon tea brought forward has again been moderate, and prices (with the exception of the commonest grades, which, in sympathy with the lower Indian and China growths, are rather easier to buy) have been firmly maintained. The quality of the teas now coming forward continues to be generally satisfactory, but really fine teas above 1s are somewhat scarce and in strong demand."

HOW TO MAKE AND DRINK COFFEE.—The decline of coffee in public favour is discussed by the *British Medical Journal*, and the reason ascribed in some measure to the ignorance or apathy exhibited as to proper methods of making and drinking it. Notwithstanding the reduction of the duty on coffee, and the fact that the best coffee is sold in Great Britain cheaper than anywhere in Europe, it is steadily falling, we read, in consumption. There are (says the authority referred to) many theories put forward to explain this. One is that coffee is more adulterated here than on the Continent. That is certainly not the case. It is easier to get pure coffee here than in France, Austria, Italy, or Germany. The next and most common explanation is that we don't know how to make good coffee here. But that again is a fallacy and its terms a misstatement. We all know how to make good coffee, and there is no one who cannot make it. All coffee-drinking races, that is to say, all the Latin People and some few of the Teutonic, understand very well that the infusion or the decoction of coffee (and, unlike tea, coffee may be and is made all over Europe almost as well one as the other) is not a fluid like tea, to be imbibed in copious draughts. A weak infusion of coffee is a tasteless and almost nauseous draught; it loses all its aroma and delicacy of flavour when dissipated in an ocean of hot water. The only way to drink coffee in large draughts is to make a small quantity of strong coffee and add to it an amount of hot milk; of course, cold milk is out of the question. That is what we all drink abroad for "the first breakfast," and find it excellent; but in England we miss the lesson, and demand of the breakfast coffee an impossibility; half a pint of an aqueous infusion of coffee, made still more tasteless very often with cold milk. So long as the British coffee-drinker persists in treating coffee as if it were tea, and swallowing it by the pint, he will always find that he gets something unpleasing to his palate.

THE ADULTERATION OF COFFEE.—Commenting on the remarks of the *British Medical Journal*, the *Daily Telegraph* points out, with truth, that: "in all probability the real cause of the falling off in the British consumption of coffee adverted to by our contemporary are precisely those which it positively repudiates as baseless and delusive, that is, the too common adulteration of the article itself with chicory and other even cheaper and nastier substances, and the prevalent ignorance in respect to the true secret of efficient and palatable preparation." It adds: "Coffee-making in its every stage—from the roasting of the berry to its final decoction in the form of powder—is an art, by no means difficult of mastery, but the study and practice of which call for close attention as well as a certain measure of intelligence on the part of its votaries. This is why it has never been adequately cultivated in England, where the rough-and-ready methods of preparing all sorts of meals are still popular, where the foreign 'culinary artist' rapidly becomes demoralised and 'forgets his cunning,' and where the rarest of household treasures is a native cook, at once painstaking in small matters and ambitious to rise above the prosaic level of 'plain roast and boiled' and of the snipid breakfast coffee that 'everybody knows how to make.' In point of fact, it is not only with respect to this beverage, so deliciously prepared in Continental kitchens, that the ignorance and perversity of English cooks make themselves daily manifest in countless insular households, but in relation to 'after-dinner' coffee as well, the native concoction of which in public and private establishments alike, is, for the most part execrable. Of this delectable liquid—at once a relish,

stimulant, and digestive—it may with truth be said that only one of its varieties is known to English coffee-makers, who seldom manufacture even that one in such sort as to make it the crowning joy of a succulent repast."

COFFEE PROSPECTS.—The reaction favouring importers, noticed at the date of our last, is well maintained. The fact of the lowest point being reached was sufficient to induce general buying (says Messrs. Wilson, Smithett & Co.), and as stocks are notably small compared with former years, competition was concentrated on the little catalogued at auction. Every description of coffee on the spot shows a further improvement in price. Considerable transactions at advancing rates are reported in Brazil descriptions, and importers are strong, holders' firmness being owned in the first place by the smallness of the receipts, and again by revolutionary outbreaks in Brazil, which, it was feared, would prevent produce reaching the coast; but this disturbing element now appears less likely. Business is, of course, restricted by the death of arrivals, the trade finding extreme difficulty in executing orders, and the new crops of various growths are anticipated with some eagerness. The only new coffee to hand at present is Jamaica, of which growth one parcel was included in the auctions. The quality of this was better than that of the first shipment, being more carefully garded, but the flavour was not satisfactory. Attention given by the plantors to the careful curing and picking will be well repaid by the enhanced sale value. Jamaica of good even bean, free from black, is in high favour with the home trade, and always commands competition when common parcels for export. Very little Costa Rica or Guatemala were catalogued. More important quantities of Colombian were sold at extreme prices. The rise during the fortnight is from 2s to 4s, making the recovery from the recent lowest point about 8s per cwt. The terminal markets have shown activity, considerable business being effected, and quotations show an irregular advance of 2s to 5s per cwt., some positions having risen even more. The statistical position again favours importers, stocks everywhere showing a further reduction with a decrease in the visible supply of the world. European stocks November 1st (tons): 1891, 48,784; 1890, 47,480; 1889, 85,600; 1888, 71,100; 1887, 140,180. European stocks October 1st (tons): 1891, 54,220; 1890, 62,000; 1889, 101,240; 1888, 76,930; 1887, 159,380. A circular from Holland gives the world's visible supply as:—November 1st (tons): 1891, 151,820; 1890, 128,804; 1889, 175,200; 1888, 150,165; 1887, 231,869. October 1st (tons): 1891, 158,730; 1890, 132,722; 1889, 182,400; 1888, 138,500; 1887, 221,200.—*H. and C. Mail*, Nov. 13th

THE TARE OF TEA.

Commenting on some remarks made in a financial paper to the effect that, by the present mode of taring tea packages, the Government lose £25,000 per annum in the shape of the fourpenny (per pound) duty, and that the producer or importer also suffers to the extent of from 1 to 2 per cent. on the net weight, the *Grocer* says:—"Almost anything can be demonstrated by figures, and, in order to arrive at this sum, an isolated instance of a small consignment of twenty-eight chests of Ceylon tea has been selected, upon which there is apparently a loss of thirty-six pounds on a net weight of 2,492 lb.; but whether this arises from the process of taring alone, or from the two operations of ascertaining first the gross weight and then the tare, is not even mentioned. The remedy for the present assumed unfair state of things is to turn out every package of tea, and have an account taken of each one. This in theory sounds just, but in practice it would be found almost unworkable, considering the very large number of packages imported, and would be undesirable to buyers, and absolutely unjust to grocers in the country. At present the Customs authorities select a certain number of packages in every parcel of tea, and if they find

the variation in the weight of the wood and lead to be of an appreciable extent the whole of the chests are turned out; so that we fail to see how the Government could possibly make any gain on every package imported, and consequently the calculation of £25,000, which is based upon a percentage of the whole of the duty now paid, is simply erroneous and misloading.

"In turning out teas, grocers often find the tare actually more than the Customs have allowed, and the weight of tea is less than they pay the duty upon, and this is compensated by the little over-weight in others, so that by taking an average the out-turn of the tea is a fair one as regards the tare. It is rather curious that Indian and Ceylon teas have been selected, for they are often bulked in London after the tare has been ascertained; and as it is almost impossible to put as much tea back into a chest when turned out, and as teas are sold on the landing weights, the grocer does not get the full weight as imported, although he may get the net weight invoiced to him. Again, Indian, and especially Ceylon, teas are known to lose some of their flavour by keeping, and particularly by exposure to the air, and, if every chest were turned out, the pressure of work at the bonded warehouses would be so great that packages would be left upon longer than necessary, and, although the importers might not suffer, as it is the custom to put teas up to auction as soon as possible after arrival, yet the buyers would have to bear the loss of deterioration by exposure, which in most cases would be not only serious, but quite uncalled for. If there is really any loss by the process of taring worth consideration, the remedy is in the grower's hands, for he can, if he likes, have the packages made of more even weight; the Assam Company do, and have done so for some years, and we have heard from several buyers that the weight of the wood and lead is in many cases so nicely arranged abroad, that the gain in weight upon the tare now is fractional, and in some cases does not cover the weight of the package."—*H. and C. Mail*, Nov. 13th.

SOME ACCOUNT OF THE NUTMEG AND ITS CULTIVATION.

By THOMAS OXLEY, Esq., A.B.,

Senior Surgeon of the Settlement of Prince of Wales' Island, Singapore and Malacca.

(From the "Journal of the Indian Archipelago and Eastern Asia.")

(Continued from page 446.)

Forest land, or jungle as we call it in these parts, can be cleared for about from 25 to 30 Dollars per acre by contract, but the planter had better be careful to have every stump and root of tree removed, ere he ventures to commence planting, or the white ants, attracted by the dead wood, will crowd into the land, and having consumed the food thus prepared for them, will not be slow in attacking the young trees. Whilst the Planter is thus clearing the ground, he may advantageously at the same time be establishing nurseries:—for these the ground ought to be well trenched and mixed with a small quantity of thoroughly decomposed manure and burned earth, making up the curb afterwards into beds of about 3 feet wide with paths between them, for the convenience of weeding and cleaning the young plants. Of course, if the planter can obtain really good plants the produce of well selected seed, it will be a great saving of time and expense to him, but unless the seed be carefully chosen, I would prefer beginning my own nurseries, and in the selection of seed would recommend the most perfectly ripe and spherical nuts. Oval long nuts are to be rejected, particularly any of a pale color at one end. Few things tend more to ultimate success than good seed, therefore too much attention cannot be bestowed upon it. I am of opinion that Planters have been hitherto very careless on this subject, hence we see such varieties of the tree, which is becoming every day what the gardeners in England call more sportive; this also

partly arises from continuing to reproduce plants from those of the place, whereas were the Planters of Penang and Singapore, to interchange their seed, it would be mutually profitable. We know that the Agriculturists of Europe find it to their advantage to obtain seed for their cereal crops from places remote, and even the inhabitants of the British Isles find it necessary to make such interchanges. It is not easy to afford a reason for this, but the fact is well established, and would appear to be the fiat of infinite wisdom for some great good, perhaps to induce indolent and selfish man by the strong stimulus of self interest to a mutual reciprocity and kindness of feeling, by demonstrating to him in so practical a manner that his own good is linked inseparably with that of his neighbour.

The planter having selected his seed, which ought to be put in the ground within 24 hours of being gathered, setting it about 2 inches deep in the beds already prepared, and at the distance of from 12 to 18 inches apart, the whole nursery ought to be well shaded both on top and sides, the earth kept moist and clear of weeds, and well smoked by burning wet grass or weeds in it once a week, to drive away a very small moth-like insect that is apt to infest young plants, laying its eggs on the leaf when they become covered with yellow spots, and perish if not attended to speedily. Washing the leaves with a decoction of the Tuba root is the best remedy I know of, but where only a few plants are affected, if the spots be numerous, I would prefer to pluck up the plant altogether rather than run the risk of the insect becoming more numerous, to the total destruction of the nursery. The nuts germinate in from a month to six weeks and even later, and for many months after germination the seed is attached to the young plant and may be removed apparently as sound as when planted, to the astonishment of the unlearned, who are not aware of the great disproportion in size between the ovule and albumen, the former of which is alone necessary to form the plant. The plants may be kept in nursery with advantage for nearly two years. Should they grow rapidly and the interspaces become too small for them, every second plant had better be removed to fresh nursery and set out a distance of a couple of feet from each other. When transplanted either in this way, or for their ultimate position in the plantation, care should be taken to remove them with a good ball of earth secured by the skin of the plantain, which prevents the ball of earth falling to pieces.

The nurseries being established, the ground cleared and ready, the next proceeding is to lay out and dig holes about 26 or 30 feet apart, and as the quincunx order has many advantages, it is the form I would recommend for adoption. The holes should be at least 6 feet in diameter and about 4 feet deep, and when refilled the surface soil is to be used and not that which is taken out of the hole. Each hole should be filled up about one foot higher than the surrounding ground, to allow for the settling of the soil and sinking of the tree, which planted over at this height will in a few years be found below the level. Over each hole thus filled up a shed, closed on two sides east and west, and proportioned to the size of the plant, is to be erected. The best substance for this purpose is I think the Attap—Malay grass and bamboo, occasionally used, have their disadvantages, the former attracts white ants, the latter when commencing to decay, breeds a black blight that is soon transferred to the plant, injuring it materially. It is not a bad plan to leave an open space in the centre of the top of each shed about 12 inches wide, by which the young plant may obtain the benefit of the dew and gentle rains, which more than compensates for the few rays of sun that can only fall upon it whilst that body is vertical. After the sheds have been completed, each hole should have added to it a couple of baskets of well decomposed manure, and an equal quantity of burned earth, when all is ready for the reception of the plant which, having been set out, if the weather be dry, will require watering for 10 days or a fortnight after, in fact until it takes the soil. As I have mentioned burned earth both for the use of the nursery as well

as final transplanting, I may as well here explain what I mean by that substance, this earth when well prepared is quite black, friable and pungent of smell, containing potash and abundant small portions of charcoal. It is eminently useful in all kinds of cultivation, rendering friable the stiff clay and affording carbonic acid to the plants. The Chinese with good reason place much dependence upon it as a manure, and most of them know very well how to make it, but unfortunately it cannot be made in every locality as it requires a very large quantity of firewood to prepare it properly, and is only really good when made of the peaty substance that forms the top surface of all the bottoms between the hills that spread over nearly the whole island of Singapore. This manure may be useless from two causes, either if over burned when it turns red and is effete, or if not sufficiently burned, when it will be filled with chips and portions of unburned wood and become a source of attraction to the white ants, by no means desirable visitors. The earth so soon as prepared ought to be placed under sheds until required for use, otherwise it loses much of its stimulating properties, particularly if exposed to heavy rains.

The Planter having set out all his trees must not deem his labours completed, they are only commencing. To arrive thus far is simple and easy, but to patiently watch and tend the trees for ten years after, requires all the enthusiasm already mentioned. About three months after planting out, the young trees will receive great benefit if a small quantity of liquid fish manure be given them. In the first six years they ought to be trenched round three times, enlarging the circle each time, the trenches being dug close to the extremities of the roots which generally correspond to the ends of the branches, and each new trench commencing where the old one terminated, they must of course greatly increase in size as the circle extends, requiring a proportionate quantity of manure, but the depth ought never to be less than two feet. The object in trenching is to loosen the soil and permit the roots to spread, otherwise the tree spindles instead of becoming broad and umbrageous. This operation might with much benefit be performed ere the roots arrive at the outer rim of the already prepared soil, instead of the usual plan of waiting until they penetrate the unloosened earth, by which many of the roots are necessarily obliged to be cut and the tree thereby checked for some months. The present plan of manuring has invariably this effect, and might be altered with decided advantage, for it can never benefit a tree to cut and destroy the extremities of the roots by which it is mainly supported. Were the trenches therefore made in an advance of the roots it would be a very great improvement in the cultivation. As the trenches are now dug for the purpose of manuring, the usual mode is to throw into the bottom of the trench all the grass that can be collected, covered by a layer of earth, tilling up the remainder with manure and earth well mixed, part of which ought to be used for top dressing having previously scraped away the surface soil so as just to expose the extremities of the roots. In time the circles extending, will at last meet, and the whole of the ground having been by that time gone over, the trees ought to completely cover the ground and top dressing will then suffice. This latter would at all times be the most economical mode of manuring, and might be given after every heavy crop, but as I before mentioned it is essentially necessary to loosen the whole of the ground, or the thick fibrous root of the nutmeg cannot pierce through, and the plant will be stunted. Some persons apply their manure fresh from the stable or cow yard. There is no question that fresh manure enriches ground more than that which has undergone perfect decomposition, but unfortunately fresh manure when brought into contact with the roots of the tree destroys them, the ends blacken and decay, and in this state, if there be white ants in the ground, they very soon attack and kill it altogether. Manure is beyond all other considerations the most important to the welfare of an estate; it is that which gives quantity and quality of produce, and without it a plantation cannot be carried on. The want of it must limit the cultivation

in the Straits, and will yet bring up many a planter, who having got his plantation to look well up to the eighth year with very little manure, thinks he can go in the same manner. But trees grows readily up to the 7th or 8th year;—it is then that really good cultivation begins to tell, and, even with the best care, trees receive a check upon their first showing fruit, but the skilful Planter about this period will redouble all his energies, knowing that he is near to his reward, and will lose it entirely if he omits to do so. The nutmeg tree likes well all sorts of manures, but that which is best for it seems to be the well rotted stable and cow yard manure mixed with vegetable matter, and when the trees are in bearing the outer covering of the nut itself is about one of the very best things to be thrown into the dung pit. Dead animals buried not too near the roots are very acceptable to the trees, also blood, fish and the oil cake imported from Java, but the greatly lauded manure of the present day, Guano, I decidedly object to. Having tried several tons of it, I am of opinion that it is the least beneficial substance that can be given to the nutmeg tree. It certainly causes the tree to assume a deeper tint of foliage and at first to throw out young shoots, but there seems to come a very unpleasant reaction afterwards, and I am inclined to think the quality of the produce is deteriorated; at least such is my conviction on the subject that I shall never try it as manure again. With respect to the best mode of preparing and keeping manure I am disposed to the plan of placing it in pits, although in Europe stacking it in heaps is I believe generally preferred, but our climate here is so desiccating that manure thus exposed will lose too much of its moisture to ferment properly, and the loss will also be much greater. Besides if it be not required for immediate use, it keeps much better in a pit covered over by a coating of earth to prevent evaporation. When required for use it ought neither to be too dry nor wet, the best state is that of an homogeneous black paste. Equal parts of this substance and burned earth, such as already described, is the stuff to produce nutmegs, and he that uses most will get most. Slovenly cultivation is the most expensive in the end, and by far the least satisfactory.

TIN MINING IN PERAK.—In the report on the Kinta district for September, we have first an account of an "amok" as follows:—

On the 3rd a Malay named Puteh Jafar stabbed his wife, brother-in-law, and brother at Ohumor. The first two died within a few days. Puteh Jafar was arrested at once and handed over to the Police; he acknowledges the crime, but gives no reason for it except that he had fever at the time.

Then comes notice of a rush into tin mining:—

On the 9th I visited the village of Mambang di Awan, in Kampar, on the Dipang-Tapah road, which has during the last two months grown from a little cluster of huts into a large and flourishing mining village with 154 shops in it. It has been laid out by the Assistant Penghulu Imam Prang Jebelumun in 60 ft. streets with the usual blocks of ten 20 ft. building lots, and is now one of the most thriving places in Kinta. There has been a regular rush into this part of Kampar, and over 1,000 acres of mining land have been taken up in the neighbourhood of the new village. Such mines as have been opened show very good prospects, especially that lately opened by Mr. Colongan for the French Société des Etain. The progress made lately in the mukim of Kampar has been extraordinary, and, from the most backward mukim in Kinta, it is fast becoming one of the most prosperous.

Again:—

Mr. Ortlepp, who is looking after the Menanglehu Lode Company's concession, has supplied me with particulars of the sale of the last shipment of lode ore which the company made to England. 100 tons of the ore contained 12½ per cent of oxide of tin and 25 per cent of arsenic, and realized £7 10s a ton. This is a very satisfactory result, and promises well for the future of lode-mining in the country.

The tin and charcoal duty for the month amounted to \$42,912 94.

AT THE ROYAL COLONIAL INSTITUTE.

On Tuesday evening, the 10th instant, I had the honour of being a guest of the Council of the Royal Colonial Institute at the dinner which usually precedes the first meeting of each session, in the Whitehall Rooms of the Métropole. Lord Brassey, looking the veteran skipper, even though a peer, was Chairman, supported by no less than three Colonial Governors or ex-Governors—Sir Wm. Robinson of Western Australia whom I saw in the Colony in 1875 and who maintains his youthful appearance in a wonderful way, Sir Wm. Jervois, the Royal Engineer veteran as well as ex-Governor, and highly artistic looking Sir Henry Blake* who with clever Lady Blake left next morning for Jamaica. There were also Sir Frederick Young (almost the Founder of the Institute), Sir Hugh Low (formerly of Perak), Sir David Tennant, Speaker of the Cape Parliament and Sir John Aokerman, Speaker of the Natal House of Assembly, a venerable genial colonist hearded like a wanderer. I was honoured with a seat not far from the Chairman and had with gentlemen of the Colonial Office, whom I found on each side a very interesting, and, I trust, materially edifying conversation. There was a very large attendance, almost entirely of colonists, and the "function" or business of dining lasted quite a couple of hours, closing with the one toast usual on such occasions—"THE QUEEN AND EMPIRE,"† briefly but felicitously proposed by Lord Brassey. Ceylon was well represented; for, besides the Attorney-General looking a picture of robust health, there were present Mr. J. R. Mosse whom I was glad to find so hale and hearty and who, as a member of Council, takes a special interest in the Institute, as well as in all that concerns Ceylon; Sir George W. R. Campbell, looking as handsome and fresh as ever, though he told me he had had a bad illness since he left Ceylon; Dr. Van Dort and Mr. F. H. M. Corbet were also at the dinner and probably some more Ceylon men—at any rate Messrs. J. L. Shand, Herbert Anderson, J. F. Churehill (white but vigorous looking) and E. B. Hurley were at the after meeting. This was for the reading of a paper by Mr. W. E. Maxwell, C.M.G., Resident at Selangor, on "The Malay Peninsula, its Resources and Prospects." There was quite a crowded gathering in the large hall to listen to this paper and the discussion thereafter. Some letters of apology were read by the Secretary, Mr. O'Halloran, including one from Sir J. F. Dickson which mentioned that he had been called suddenly away on public business, I think to Gibraltar if I heard aright. A very large total of new members was announced for this year, and the Institute altogether is now a most influential as well as representative body, so that it is no wonder if, as Sir Frederick Young told me, the Council and Fellows have no idea of allowing themselves to be swallowed up by the Imperial Institute. If there is to be Union or Amalgamation, it must be on an equal platform. The delicate point is, of course, that H. R. H. the Prince of Wales is President of both Institutes; but there is no immediate movement, the big building for the "Imperial" being now only under construction in West Kensington, while the "Colonial" is very comfortably accommodated in Northumberland street.

Mr. Maxwell's paper proved a very interesting one

* Whom the highly aristocratic Queenslanders refused to receive as Governor, because, forsooth, he had worked his way up from Police Inspector! In that case it was the Colonial snobs and not the Secretary for the Colonies whom Lord Carrington ought to have denounced.—Ed. T. A.

written in a clear, practical fashion, and he himself is evidently the right man for Resident in a Native State, straightforward, energetic and altogether an attractive personality. I send you the complete paper in print, but will only venture to mark a few extracts. He began as follows:—

To the early days of the East India Company it was to the Farther East, rather than to the territories which now constitute British India, that English merchant adventures turned their eyes. In the reign of James I. the East India Company traded with seven ports or states in Sumatra, four in Borneo, and four in Java, and factories were established at most of those places. At Patani, on the East Coast of the Malay Peninsula, they had a factory (that is to say, a place of business where two or three Englishmen traded with the natives and collected produce for shipment to England) from 1612 to 1622. At this time our commerce with Hindustan was in its infancy, and Englishmen at Surat Broach, Agra, and Ajmere were making timid ventures in the country of the Great Mogul. That the men who, settling for trading purposes on the banks of the Hooghly, laid the foundations of the city of Calcutta and the great Bengal Presidency, had served a novitiate in Malayan countries is proved by some of the words which they and their Malay servants and seamen carried westward with them.* These still have a place in the Anglo-Indian jargon which the late Sir Henry Yule has so well described. We have so long been content with a second place in the East Indian Archipelago that the story of the long struggle between English and Dutch traders for supremacy there (the object being the trade of the "Spice Island"†) is almost forgotten. The brilliant history of our achievements on the continent of India supplies the reason for our gradual abandonment of much that we coveted and fought for in remoter regions. Though the places with which the English East India Company traded in India proper gradually fell into the possession of the servants of that Company, their stations in the islands and ports of the Eastern Archipelago were one by one abandoned in favour of the Dutch. We were driven by the Dutch from the Spice Islands in 1620, and from Bantam and Jakarta in Java in 1683. Expelled by their influence from Bantam, we established ourselves in Bencoolen (*Bangka Ulu*) in 1685, "our sole and humble object being to secure a share in the pepper trade."‡ Little more than a hundred years ago the only English station east of Cape Comorin was Bencoolen, on the West Coast of Sumatra.

The Settlements which we now possess in the Straits of Malacca, namely, the islands of Singapore and Penang, and the territory of Malacca, are remarkable as having been originally Indian Colonies. Calcutta, not London, was responsible for their first acquisition, and conducted their government until 1857. Penang, which occupies a commanding position at the Northern end of the Straits of Malacca, was occupied by the orders of the Supreme Government, then under the presidency of Sir John Macpherson, in 1786. Malacca was taken from the Dutch (by an expedition sent from India) in 1795. Singapore was acquired (by cession from the Malays) in 1819, by Sir Stamford Raffles, acting under the authority of the Governor-General of India, the Marquis of Hastings. These places continued to be outlying portions of the great Empire of India until twenty-four years ago, and were, at the time of their recognition as a Crown Colony, being governed from Calcutta.

Early in this century events happened which might have given us that supremacy in the Eastern seas which

* I may instance the following words, well-known in British India, which are really Malay: *Compound*, the Anglo-Indian term for an enclosure round a house, is the Malay *kampung*, a plantation or orchard. *Godown*, a merchant's warehouse, is a corruption of the Malay word *gedong*, a brick house. *Bankshall*, the port-officer's place of business at a seaport, is easily recognisable in the Malay *bangsal*, a shed.

† Amboyna and the Moluccas.

‡ Crawford, *Descriptive Dictionary*, p. 73.

as I have already pointed out, we had gradually resigned to the Dutch. During the occupation of the Netherlands by the French, the Dutch Colonies in the East Indian Archipelago fell into our hands; an expedition, fitted out in India, under the command of the Governor-General, Lord Minto, having taken Java and its dependencies in 1811. We did not keep Java. With the fall of Napoleon, Holland was again made independent and Java was restored to her, no doubt in consequence of a wise and statesmanlike recognition of the fact that the retention by Holland of the principal of her Eastern colonies is essential to her vitality as a European Power. The creation of an important commercial emporium at Singapore was, however, the natural outcome of the surrender of Batavia, and the position of Great Britain in the Far East has since been further strengthened by the acquisition of Hong-Kong, and by the wonderful development of our Colonies in Australasia, to which I may add our recently-established protectorate over Sarawak and North Borneo.

Since 1824, when a treaty was made between Great Britain and Holland defusing the spheroid of action of each in Malayan waters, we have of necessity confined ourselves to the peninsula of Malacca, the islands of Penang and Singapore, and the parts of Borneo just mentioned.

My object in addressing you this evening, at the invitation of the Council of the Royal Colonial Institute, is to attempt a brief description of what is being done towards opening up the Malay Peninsula, the field which we reserved to ourselves when we voluntarily retired from all further political connection with Java and Sumatra. The period of active British interference in the Malay States of the Peninsula dates from 1874 only. For fifty years after the cession to the Dutch of Beencoolen, in Sumatra, in exchange for Malacca, we confined ourselves to the two Indian Colonies (Penang and Singapore) which I have described as having been planted in the Straits of Malacca by the English in Bengal, and to the old Portuguese and Dutch Colony of Malacca, which had become ours by cession. The Government of India called their remote dependencies by the collective title of "the Straits Settlement" (in the singular), and supported them for years at the expense of the Indian tax-payer. Little was known of them in Calcutta, where, however, difficult questions connected with their administration caused infinite trouble from time to time. "These details may appear to your Lordship to be petty," wrote an Indian official apologetically to Lord Auckland in 1837, discussing some project relating to Straits finance, "but then every thing connected with these Settlements is petty, except their annual surplus cost to the Government of India!" It is amusing to recall an official remark of this kind now in 1891, when the Colony of the Straits Settlements, with a history of twenty-four years of independent existence as a Crown Colony, may, in spite of recent temporary reverses, fairly claim to be the most prosperous and successful of all the Crown Colonies, having a revenue of four and a half million dollars, surplus assets (at the beginning of 1891) of two and a half million dollars, and no public debt.

Later on, he referred to the transfer of the Settlement from the Indian to the Colonial Office authorities:—

During the time that the Government of India governed the Straits Settlements their relations with the Malay Rajas of the Peninsula were always friendly; but the native States were rarely visited by British officials, and their internal affairs were scarcely in any way influenced by our advice or counsel. Treaties of alliance and friendship were made from time to time with all the Rajas on the west coast, Kedah, Perak, Selangor, and Johor. When, in 1858, the Queen's sovereignty over India was proclaimed, each Raja found in the proclamation (which was translated into Malay and sent to each native court) a Magna Charta of his rights in the following memorable words:—

"We hereby announce to the native princes of India that all treaties and engagements made with them

by or under the authority of the Honourable East India Company, are by us accepted, and will be scrupulously maintained; and we look for the like observance on their part.

"We desire no extension of our present territorial possessions; and while we will permit no aggression upon our dominions or our rights to be attempted with impunity, we shall sanction no encroachment on those of others. We shall respect the rights, dignity and honour of native princes as our own, and we desire that they, as well as our own subjects, should enjoy that prosperity and that social advancement which can only be secured by internal peace and good government."

I do not think that I need enter into any detailed description of the circumstances which have led to the appointment of British Residents in certain States of the Malay Peninsula, to exercise a control which should secure "the rights, dignity, and honour" of the native princes whom they are instructed to advise. It will be sufficient to say generally that the chief, or, at any rate, the proximate cause has been the presence in large numbers of Chinese in the Peninsula, and the powerlessness of the Malays to control them. Then came the era of Residents for the native states:—

The Sultans of Perak and Selangor, the two States which are the centres of the tin-mining industry, asked in 1874 that British Residents might be associated with them in the government of their respective States. Sungei Ujong, a small State to the south of Selangor, which also possessed a somewhat intractable Chinese mining population, accepted a Resident in 1875. Later, in 1883, Governor Sir Frederick Weld induced the group of small States lying between Sungei Ujong, Pabang, Malacca, and Johor (called the Negri Sembilan, or the Nine States) to confederate and to conduct their government under the advice and with the assistance of a resident British officer. Lastly, in 1888, in pursuance of an agreement between Sir Cecil Clement Smith, the present Governor of the Straits Settlements, and the Sultan, Pabang, a large State on the East Coast of the Peninsula, was added to the number of the Protected States, and its administration on an improved footing was made impossible by the appointment of a British Resident.

The names of the Malay States in which British officers are stationed do not by any means exhaust the list of the States on the Peninsula. To the North of Province Wellesley (a dependency of Penang) there is the ancient kingdom of Kedah, shorn of three of its provinces, Perlis, Sital, and Traug, which now form semi-independent States. These are, in a sense, subject to the suzerainty of Siam. Further north, again, there are numerous small provinces or governorships under the direct control of Siam. The indigenous population here is Siamese and not Malay, and these little States are chiefly interesting to us, because the settlers there include many (Chinese) British subjects. Indeed the Governors of two of these provinces are Penang Chinese, and in many places the authority of the Siamese seems to be overshadowed by that of a powerful Chinese secret society (the Ghi-Hiu). They are visited annually by the Resident Councilor of Penang, who is British Consul for this region.

On the East Coast, the purely Malay States are Patani, which had a long history as an independent State, and where the factors of the East India Company had an "honourable reception from the queen and country people" in 1612. It was laid waste by the Siamese in 1818, and is now subdivided into seven provinces under separate petty chiefs. To the south, again, are Kelantan and Trengganu, virtually independent. At the extreme south of the Peninsula is the protected State of Johor, the government of which is conducted by its energetic and enlightened ruler with the aid of advisers chosen by himself.

Respecting the result, passing over a good deal, I quote as follows:—

The progress of States like Perak and Selangor can be illustrated in a striking manner by statistics, showing the extraordinary growth of the revenue since 1875. But statistics of this kind are, in my

opinion, misleading. Given abundant deposits of a valuable metal (two-thirds of the tin produced in the world is exported from the Straits Settlements), and given a Government, even a bad Government, strong enough to maintain order and to make the trader feel sure that he can keep what he gains, there is certain to be an ample revenue. There is no reason why a corrupt and selfish Government should not have sufficient financial sagacity to discover all reasonable sources of income, and at the same time avoid imposing on the people a burden of taxation which would deter immigration and diminish industry. Again, causes which do not arise within the State itself may unexpectedly, and not as the result of any conscious effort on the part of anyone connected with the Government, produce a great accession of revenue. For instance, the proximity of Johor to Singapore gives the former State a larger Chinese population, and consequently a larger excise revenue, than it would otherwise have. I do not therefore wish to say merely, "Just look at our balance-sheet, and see what we have done." It is by the application of the revenue for, as we believe, the best interests of the people that we and our work must be judged. The revenue of those States which have British Residents has been energetically employed, by their advice, in public works of all kinds, a civil list being first set apart for the maintenance of the Rajas, chiefs, and headmen of the State, and due provision being made for the payment of the police force and of the establishment of the various public offices.

PERAK.—The State (7,940 square miles) is divided into six districts—Larut, Kuala Kangsa, Kinta, Batang Padang, Lower Perak, and Krian. Taiping, in the Larut district, is the principal town, and it is here that the Resident lives. The Sultan (Raja Idris bin Iskandar, c. m. a.) prefers to dwell, like his predecessors from time immemorial, on the banks of the beautiful river Perak, and a palace is being built for him at Kuala Kangsa. A line of railway, eleven and a half miles long, connects the mining districts in Larut with the sea, and in Lower Perak work has commenced on the first section of the Kinta Valley Railway, a line which is designed to run from Teluk Anson to Ipoh, a distance of fifty miles. The open line in Larut is worked at a profit to Government of about 6 per cent.

Perak possesses no less than 138 miles of metalled cart-road, and each year the work of road-making is continued with the object of giving complete communication to all parts of the State. Besides first-class roads, there are unmetalled cart-roads and bridle-paths in many districts. The head judicial authority in the State is the Chief Magistrate (an English barrister). The public buildings in the State include Government offices, houses for officials, excellent barracks for the Sikh police, police-stations in all districts, a prison with cellular wards on the modern system, lighthouses, a museum (chiefly geological and ethnographical, founded by Sir Hugh Low, and well arranged and managed by Mr. L. Wray, junr.), schools, &c. The town of Taiping is provided with excellent drinking water brought in pipes from the nearest range of hills. There is telegraphic communication throughout the length and breadth of the land, and the completion this year of the principle line to a point where it joins the Selangor boundary enables messages to be sent now from Penang to Malacca by the Native States lines. The population, according to a census taken in 1891, is 213,000 including the unexpected number of 100,000 Malays; the revenue in 1890 was \$2,594,116. On Jan. 1, 1891, the State had a surplus balance of more than \$2,000,000, of which about \$1,500,000 was invested in Indian or other securities. There are thus funds in hand to meet the cost of the construction of projected railways.

In Selangor progress has been equally remarkable. The State (3,000 square miles) is divided into six districts—Klang, Kuala Lumpur, Kuala Langat, Ulu Langat, Kuala Selangor, and Ulu Selangor. The town of Kuala Lumpur is picturesque situated in the upper portion of the valley of the Klang River. From it good cart-roads radiate to the Perak frontier on the north-east, fifty-six miles distant, and to the Sungai

Ujong frontier on the south-east, thirty miles distant. A line of railway twenty-four miles long connects the capital with the port of Pangkalan Batn, on the Klang River, the river being crossed by an iron railway-bridge 473 feet long. This short State line is, I suppose one of the most paying railway properties in the world. Having an up and down traffic, that is to say, carrying all the rice and other foodstuffs up to the mines and bringing all the tin down, it pays about 1½ per cent., though the tariff of charges is not a high one. This line is now being extended thirty-eight miles in a north-easterly direction, tapping a district known to be rich in tin. I hope that by the end of this year twenty-three miles of this extension (which was projected by my predecessor, Mr. Swettenham, with the sanction of Sir C. C. Smith) will be open and that 1892 will see the whole completed. Further railway extension is in contemplation; but whether this will take the form of a further advance in the direction of the Pahang border, or whether we shall improve our sea communication by carrying our railway coastward to a point on the Klang Straits where there is a deep sea harbour, I cannot at present say.

The revenue in 1890 was \$1,833,928, and on January 1st, 1891, the Government had a surplus balance of \$720,000. This is being applied in the construction of railways; and in this connection it may be desirable to state that the railways in Perak and Selangor are exclusively the property of the State, and have hitherto and are being constructed out of revenue, no recourse having yet been had to loans.

Then as to Resources in Mining and Planting, the following are representative extracts:—

What field is there, then, for the successful employment of European capital in the Peninsula? I will deal first with mining, and then with agriculture. There were exported from the Protected Native States in 1889, 413,386 *pikuls*, or 26,392 tons, of tin, and in 1890, 450,777 *pikuls*, equal to 28,173 tons of tin. At 86½ a ton, which is a fair average price, the metal exported in 1889 was worth 2,269,712½; while the estimated value of that of 1890 was 2,422,878½. With insignificant exceptions the whole of this money less the royalty or export duty charged by Government, has gone into the pockets of the Chinese. Is it then impossible for Europeans to get a footing in the mining districts and work their claims at a profit? Not at all, I think, if mining adventurers are content to being in a modest way; but the events of the past few years justify the most extreme scepticism as to the possibility of the success of an English company formed to work an untried concession.

To summarise the general purport of these remarks, the European mining adventurer, whether an individual or a company, should, to be successful—(a) Deal direct with the Government for mining land instead of buying from a middle-man. (b) Start with a small capital, and consequently with a small labour force, which can be superintended with moderate ease. As experience is gained the works, if successful, can be extended, and the labour force increased. (c) Imitate the Chinese, and spend as little as possible on anything that is not directly remunerative. The resources of the Peninsula in respect of gold are so vaguely known that I am able to say little about them. The precious metal may be found in sufficient quantities to pique curiosity, arouse avidity, and incite speculation, and yet the most diligent search may result in the discovery of nothing that will pay a dividend. The existence of gold in the Batang Padang district in Perak has long been known. The Perak Administration Report for 1890 mentions the discovery in that district of "tin-stuff rich in coarse gold;" and the Resident adds: "This district has always produced stream gold, but no attempt has been made to make gold the principal object of mining, nor to search for it in the reef."

For every ton of metal produced in a year at least four coolies must be employed. One hundred coolies will work out ¼ acre of an ordinary tin-field in a year. To produce yearly 250 tons (value at 86½, 21,500½.)—and less, I suppose, would not be satisfactory

to investors—1,000 coolies must be employed. Now the European employer who can control a labour force of 1,000 Chinese is rare in the Straits Settlements.

Let us see what advantages the Peninsula has to offer to agriculturists. Rice grows well, and is cultivated by Malays for their own food. The rice of the country is preferred by Malays to imported rice, and commands a slightly better price than the latter. But it cannot be cultivated on a large scale to compete in price with that of Borneo and Siam, which is the staple article of diet of the Chinese population of the Straits Settlements, Natives and States.

Cocoanuts and fruit-trees pay the native proprietor well, and at the various mining towns there is a steady demand for produce of this kind. In market gardening, however, the Malays do not attempt to compete with the industrious Chinaman.

Excellent pineapples can be grown, and in Singapore quite an important trade has sprung up in this fruit, large quantities being preserved in syrup and exported to Europe.

Gambier (*Uncaria gambir*, Roxh.), the shrub which produces the gambier of commerce, largely used in the tanning industry, grows to perfection in the Malay Peninsula, and Chinese have introduced it in Selangor on a concession of 11,000 acres granted for the purpose. It has long been grown extensively in Singapore and Johore, where the Chinese population employed in this industry is very considerable.

Coming now to products with which the English planter is more familiar, I must mention sngar, coffee (both Liberian and Arabian), tea, pepper and tapioca. In respect of all of these we are long past the stage of experiment. Sngar-cans cultivation has long been carried on in Province Wellesley (Penang), and one important estate has been opened in Perak, under European management; while in the same State there are 21 Chinese-owned sugar estates with an area of 21,663 acres which employ about 5,500 labourers, and last year exported 84,352 *piculs* of sugar, valued at 401,122. But here, as in other parts of the world, the competition of beet-sngar is felt, and, with the Straits sugar-planters appealing to Government for special assistance in respect of their labour supply, English capital for new estates may not be forthcoming at present. Our planters probably have much to learn from those of Java in regard to machinery and cultivation; and as long as there are improvements not yet adopted by them for cheapening the cost of producing cane-sugar, they seem to have the alleviation of their difficulties in their own hands.

In Perak, the prospects of the only estate on which the cultivation of Arabian coffee is carried on are said to be excellent, and there are miles and miles of mountain ranges on which this product can be grown. It may be hoped that the check which coffee-planting received in Ceylon will not for ever hinder the extension of this industry in the Malay Peninsula. Liberian coffee, however seems at present to be the favorite, because the safer article of cultivation. English and Scotch planters are hard at work in Perak, Selangor, and Sungei Ujong, and the various Governments are deeply interested in their success. It has been proved in Selangor that a return of nine or ten cwt. per acre may be expected.

Now that Ceylon tea has achieved such a marvellous success, it may be hoped that that Colony may send us some experienced tea-planters, for there is little doubt that the Malay Peninsula is as well adapted as Ceylon for this particular cultivation. A sample of tea grown on a Government plantation in Perak was sent to London in 1889 and favourably reported on, and we do not despair of seeing "Malay tea," as well as "Ceylon tea," an article of consumption in England.

Pepper is doing well on a small scale in Perak and Selangor. This is an old industry which has been resuscitated. It was one of the staple products of the Island of Pinang before 1810, and at one time more than 3,000 *piculs* were exported annually. But a serious fall in price led to the gradual abandonment of the cultivation. The Chinese gambier planters generally unite pepper cultivation with their main industry, as the refuse from the gambier vats makes excellent manure for pepper plants.

Tapioca is extensively grown in Sungei Ujong and Negri Sembilan, and there is one good estate in Selangor. The objection to this cultivation, on the system pursued by the Chinese, is that it involves the exhaustion and abandonment of a great area of land.

An interesting experiment in rearing silkworms has been made in Perak. The mulberry can be successfully grown in the Malay Peninsula, and already the pioneer Chinese cultivator has sent six cases of cocoons to China, where the silk is wanted. It is officially stated that the silk produced is excellent and unusually white, and an extension of this industry may be looked for, as Chinese are already taking up land for mulberry cultivation.

Fortunes have been made in tobacco cultivation in Sumatra, and I wish that I could hold out to my countrymen a reasonable prospect of rivaling on the mainland the plantations of Dell and Langkat. The tobacco leaf produced there is of an attractive, light colour, and fine, silky texture, and it is used almost exclusively for the outside leaf, or wrapper of cigars. There has hitherto been a great demand for it in America as well as in Europe, but it is said that the McKinley tariff is operating unfavorably on the trade in this product, which has been established between Amsterdam and New York. Apart from this, it has yet to be proved that in the Malay Peninsula there is any place where tobacco can be cultivated under the favourable conditions as to soil and climate which are offered on the East Coast of Sumatra. I have seen splendid specimens of tobacco plants grown in Perak, but any successful experiment must satisfy commercial exigencies, both as to quality of leaf and weight to the acre. It is in the latter particular that a tobacco estate on the West Coast of the Peninsula is likely to be found wanting.

Reasoning from the analogy of situation, aspect, &c., I should feel disposed to expect greater success in tobacco cultivation on the East Coast, and I should like to see a really business-like experiment tried by one of the numerous companies who hold land in Pahang.

As far, therefore, as the agricultural resources of the Peninsula are concerned, I may say that we have a climate suited to the production of all kinds of tropical produce, and soil fairly adapted to every sort of tropical cultivation. But, as I have already described the peninsula as being sparsely inhabited, it may be easily surmised that there is considerable difficulty about the supply of labour.

The time at my disposal does not permit me to enter into a disquisition on the labour question, and indeed the details of the subject are foreign to the object of this paper. It is enough to say that as the indigenous population is neither sufficiently numerous nor sufficiently industrious to furnish a permanent and cheap supply of agricultural labour, recourse is had to the labour-markets of India and China. The supply of coolies is a trade, giving employment to recruiters, brokers, shipping-agents, depot-keepers, and a host of other people. An artificial system of this kind, dealing as it does with men's liberties, and perhaps lives, requires careful watching on the part of a Government. The coolie must be protected, but if the labour obtained is not cheap the planter says that it is of no use to him. The difficulty is to secure to the coolie all that he is entitled to, and at the same time satisfy the employer.

Intending planters can get any quantity of good Tamil coolies from India if they will give the rate of wages which is given to men employed on Government works. The term of agreement is three years, at the expiration of which the coolie is free to seek work where he likes. The planter must not expect, nor can I understand why he should wish, to keep on his laborers against their will after the expiration of their agreements. Chinese labour can always be obtained, though the competition of the Sumatra tobacco estates makes the bounty-money high. Javanese coolies are also used a good deal by planters.

Land can be obtained on easy terms. The Perak Government is advertising special inducements to Englishmen of capital and enterprise, and, as the States do not enter into competition with each other, I think that I may say that these terms may be had in any of the Protected States of the Peninsula.

The first ten approved applicants may select blocks of 1,000 acres, or two blocks of 500 acres each, which will be given free. After the end of the second year of occupation, a rent of 20 cents an acre will be payable; or, if desired, this may be commuted by one payment of \$3 an acre. If the block selected has road frontage, the depth must be three times the frontage. A *bona fide* commencement of cultivation must be made within twelve months after selection. Cost of demarcation, survey, etc., must be borne by the lessee. The Government reserve the right to levy an export duty not exceeding 2½ per cent.

Applications addressed to the Resident of any one of the Protected States, or to the Colonial Secretary, Singapore, Straits Settlements, will receive immediate attention.

Finally, by way of summing up, I mark a few passages:—

Our hopes, of course, rest almost entirely on the tin-industry. Tin is the factor which governs everything in these States. We cannot expect to establish in the Straits of Malacca another sea-port for occuboro trade, when we already have Penang on the north and Singapore on the south. And in the absence of an indigenous agricultural population like that which any district in Java possesses, the progress of cultivation must be slow. Even if we could hope for the conspicuous success attending a particular cultivation which we have seen illustrated in Deli (Sumatra) in the case of tobacco, and in Ceylon in coffee and tea, it would not compare in immediate results with a successful mining rush. When the price of tin is high, fresh mines are opened, and coolies and capital pour in from China; with the increase in population the excise revenue goes up, lands and houses increase in value, and a general impulse is given to everything. And so, on the other hand, if low prices rule persistently for some time, inferior mines have to stop work, coolies leave the State, the excise farmers are ruined, and there is general depression.

Supported by splendid mineral resources, the principal States have, unlike the British Settlements in the Straits of Malacca, been able to establish their financial independence within a few years of their first start under British guidance. They can thus construct their roads and railways now out of revenue, acting as if tin might some day fail them. Not that I think that there is any reason to fear that the tin deposits of Perak and Selangor will be exhausted within any period that can practically concern us. We may, I trust, look forward to fresh discoveries in these States when the tin-fields, only partially open out as yet, show signs of diminished production. And, as in the case of gold-mining in Australia, we may hope that when the alluvial deposits are exhausted, lode-mining may take its place. In the Perak Administration Report for 1890, discoveries are mentioned, but lode-mining, which seems to offer to European enterprise a better field than alluvial mining, has not yet taken a foremost place in the industries of the Peninsula.

This brings me to the subject of railway construction in the Peninsula generally. There are advocates for a trunk-line, or inter-State line, which would run north and south, connecting all the States between Singapore and Penang, and which could at some future time be extended northwards through Siamese territory to meet an Indian line at Tenasserim. This is a favourite idea of those who indulge in visions of a short route from India to Australia. It is combated by others who concur in the views expressed by Sir F. Dickson, when administering the Government of the Straits Settlements last year, that, "with so fine a highway as the Straits of Malacca, ready made and costing nothing for maintenance, no such line is required, or can be required, for many years to come." Leaving engineering difficulties out of the question, we may probably assume that neither India nor the Straits Settlements will find the money to carry out at one time an undertaking of this magnitude, and that if ever our Australian fellow-colonists find it absolutely necessary to shorten their sea-voyage to England to this extent, the line must be built with Australian capital.

But the extension of inter State railway communication is much to be desired, and it seems to be not only reasonable but politic to keep in view in all railway extension now projected the possibility of through-communication being established at some time or other. Land-communication by rail with the food-producing districts (Siamese) in the north-eastern part of the Peninsula would be of incalculable benefit in time of war to the Straits Settlements and to the Empire, of which the coaling-station of Singapore is an outpost.

I have often regretted that the studies of learned Dutchmen in the field of Malayan literature, ethnology, &c., are so little known to us, owing to the general want of acquaintance, on the part of Englishmen, with the Dutch language. Among the subjects which candidates for cadetships in the Straits Settlements may take up is Italian. But Dutch has no place, an omission which might well be brought to the notice of the Civil Service Commissioners. I should like to see Dutch made an obligatory subject.

An ample revenue is being realised in Perak and Selangor, even though a temporary check is being experienced in financial progress. Let me say in conclusion that a Resident aims at being nothing more than a faithful agent of the Governor of the Straits Settlements, and faithful friend and adviser of the Malay Sultan whom he advises, and whose government he carries on. A distinguished Governor once quoted to me the candid admission of the chief official member of a Colonial Council that, "when a Colonial Secretary begins to think that he is a statesman, it is time for him to go on leave." Statesmanship the Resident is content to leave to the Governor, occupying himself with the busy post of Administrator, supported and fortified, if he deserves it, by the confidence and goodwill of his chief. I should deprive myself of a pleasure, and should deem myself ungrateful if I did not take this opportunity of acknowledging the lessons learnt and encouragement received from such men as Sir Andrew Clarke, Sir William Jervois, Sir William C. F. Robinson, Sir Frederick Weld, and Sir Cecil Clementi Smith, who have successively governed the Straits Settlements during the last sixteen years—a period untalented for steady advance in the strength of our administration in the colony proper, and in the organisation of civilised government in the Malay Peninsula.

The paper was read after a business-like fashion rather than with elocutionary grace, and then the Chairman called on Sir Wm. Jervois, as an ex-Governor of the Straits, to open the discussion, which he did in a commendatory speech with interesting reminiscences of his experiences in the early days of the Residencies, where he used to be in mortal dread of the Selangor salute, knowing the crazy old gun which was being utilised, and how when he had given an offhand invitation to a Sultan to visit him at Singapore, it resulted in 100 men and 50 women coming down for entertainment in one of Her Majesty's vessels! Sir Wm. Robinson, also an ex-Governor, followed, pleading however that his single year's experience of the Straits, did not enable him to say much. He contented himself chiefly with reading some appropriate and amusing extracts from a lecture delivered in Australia on "Social Life among the Malays." The white-haired and bearded veteran Sir Hugh Low followed with much that was interesting, showing how his heart was still in his old work if only the doctors would permit him to return, and urging that the authorities might adopt a more liberal policy in reference to the planters and their labour requirements, by importing direct all the coolies required for public works, &c. Sir Hugh believes that there is no chance of the tin mines being worked out for many years to come.

I was next, unexpectedly called on by Lord Brassey to speak—I have been asked to take part, but expected somewhat more of a general discussion first, with one or more Straits Colonists leading off—

Mr. J. L. Shand told me afterwards that he had been asked to speak on the paper, but gave me preference—all of which shows how the authority of "Ceylon" is looked up to! My remarks were somewhat as follows:—

"My Lord, Ladies and gentlemen,—I am full of admiration for the clear, concise and practical way in which Mr. Maxwell has prepared his paper considering the largeness of his subject. Some of us may have regretted the omission of all reference to such administrative difficulties as may be connected with the repression of gambling, the regulation of the opium traffic and sale of intoxicating drink; but we can understand how impossible it would be to find room for all that might be said. My interest in the planting divisions of the Malay Peninsula arises through prolonged residence in Ceylon and the opportunity of watching closely the rise and progress of the Straits Settlements. But before alluding to this, I would venture on one correction of Mr. Maxwell's paper where he speaks of the probable reason why, on the peace following on Waterloo, Java was given back to Holland, namely that it was essential to her vitality as a European Power. It must be remembered that the British had taken Ceylon as well as Java from the Dutch and that to the former England had no claim due to previous settlements or occupation, such as told in the case of Java; but the explanation we have always had why the much larger and richer island of Java was given back in place of Ceylon, is that it was urged that Ceylon was vital to the holders of India—that the grand naval harbour of Trincomalee especially was the key to the Bay of Bengal, and commanded the traffic of Calcutta, Madras and Bangoon. I mention this fact because it has an important bearing on certain controverted questions of great interest to us in Ceylon at present. (Hear, hear.) It is very satisfactory to hear of the large surplus revenue saved in the Straits to devote to Railway Extension and other public works, and one cannot help regretting that a similar wise policy was not adopted in Ceylon many years ago with reference to the proceeds from Crown Land Sales and surplus railway receipts. I also cordially endorse Mr. Maxwell's opinion that the Dutch language ought to be learned by Straits cadets, for a recent visit to Amsterdam showed me how much of great value to administrators, planters and merchants was published in that language. But now to turn to "planting." I must be remembered that between 1881 and 1886, some 400 planters left Ceylon in consequence of the failure of "Coffee" and wandered all round the tropical and sub-tropical world. The Straits Settlements, Sumatra and North Borneo especially got a large share—the last was indeed named "New Ceylon." Others went to Queensland and New South Wales, Fiji, Natal, West Indies, South and Central America—the President of Guatemala got a Ceylon planter to open a model coffee and cinchona plantation, and in 1881 I followed some of our ex-planters to California and Florida where they were orange-growing. But in the Malay peninsula—at Johore and at Perak—some of them went to work on the old products, Arabian and Liberian coffee, and although they experienced the usual proportion of disappointment as pioneers, still it is gratifying to know that a certain amount of success has been achieved with the promise of a good deal more. I know this from private as well as official reports, and it is one of the great advantages of Straits planters that from the outset they have the countenance and assistance of most sympathetic and interested officials. (Hear, hear.) It has not been so always in Ceylon. For planters

there too, there is offered forest land on the easiest, cheapest terms; there are roads and railways ensuring cheap transport, and freight to Europe must always be safe at economical rates. As to labour supply, experienced planters of the right sort with a liberal enlightened Government can be trusted to overcome any difficulty in this direction. But now, as to the all-important matter of the products to be cultivated: I have a strong opinion that the Straits planters would do wisely to make coffee and pepper their principal products, as two articles the demand for which at present and in prospect is likely to exceed the supply. In respect of coffee since the failure in Ceylon, India and Java, the world is nearly altogether dependant on Brazil and no one can tell how soon the large crops there may fall off or be interfered with by revolution, &c. Then in the Malay Peninsula, the conditions are favourable for overcoming the fungus pest (should it appear)* which ravaged Ceylon and India: isolated plantations on virgin soil surrounded by forest can be opened, and heavy crops securing high prices have already been reaped; I must certainly offer a word of warning in respect of tea which is already in danger of being overdone, as falling prices show, in Ceylon and India. ("Oh!") I speak as much in the interest of Ceylon planters now connected with the Straits as of our own tea planters. Unless new markets are got for our teas, no one would advise more tea land to be opened. I have just returned from Austria and Germany where I have been trying to get the people and dealers to use more Ceylon tea, and in Holland I was much annoyed to find how little the Java tea planter had done to make a market for their product which, instead, is nearly all sent to London.—In conclusion, My Lord, I would with, I am sure, the concurrence of Australian colonists present, press the importance of developing the planting (or farming) industry as well as mining in the Straits. No country dependent on the latter alone can be said to be in a stable position. As regards the "stream gold" to which Mr. Maxwell alluded, I am reminded of an Indian saying in reference to this most widely distributed of metals, it is that the natives of Southern India when they have no other work go and work for gold in the nearest river and make two *panams* (3d) a day and it is on record that one made one day four *panams* (6d). (Laughter and applause.) Lord BRASSEY moved a cordial vote of thanks to the lecturer in appreciative terms, to which Mr. Maxwell responded, thanking the various speakers and proposing thanks to the Chairman, and so at 10 p.m. ended a very largely attended and pleasant gathering.

SOUTH INDIAN AGRICULTURAL PRO- VERBIAL PHILOSOPHY.

(Concluded.)

Of the next series of proverbs Mr. Benson says:—By far the most interesting series of sayings, &c. regarding the seasons are those which follow, No. 117 to 196. These are all based on a system whereby the year is divided into 27 astral periods, called *Karthulu*, which are specified on the margin. By these the ryot regulates all his agricultural operations, and it is thus that a study of the sayings affords a very good idea of the characteristics the ryot expects, desires, and dreads in the weather throughout the year. The great bulk of the sayings refer to the busiest part of the agricultural year, which is usually over except in so far as harvest is concerned, by December. Rain early in March is unusual, but occasionally

* It has long existed in Java and the Straits, though not quite with such virulent effect as in Ceylon and India.—ED, T. A.

heavy storms (117) do occur. Later on it is not so uncommon and the peculiarities (119) ascribed to its falling at different times between the middle of March and the beginning of May are not easily understood. That rain during the latter part of April should be so unfortunate (No. 120 and 121) is not explicable, especially when the fall of rain rather earlier (No. 118) and rather later (No. 123) is so highly prized. The usual extreme heat experienced in May and in June, if no rain falls, is noticed. Special attention is called to the value and importance attached to the June rains, although, as No. 126 shows, the usual fall in that month is light. The *mongari* crop alluded to in No. 130 is the early crop. A special value is attached to a good opening of the season, and if the rain does not come in Mrugasira it is ardently looked for in Arndra. In the latter period, the fall should be heavy—not drizzling—No. 136, and fears for the future will disappear. Following this, a spell of drier weather with light showers is expected (Nos. 137—142), from the beginning of July to the middle of August, during which the early sowings may be pushed forward.

We quote a few specimens of the proverbs:—

Rain in Mrugasira will make even an old hullook bellow.

If rain falls after thunder in Uttara, if the king acts unjustly, and if the white-ant gets wings, the sequel will be very hard.

If there be no rain in Chitta, even an ant will suffer from heat.

The influences believed to be exercised over the weather by certain stars or their conjunction, and by certain natural phenomena, is shown in the next series of proverbs, from which we quote the following:—

The labours of a grumbler and thunder before rain will end in nothing.

If lightning flashes in the west, even a pig would not approach the water-course.

If the fowl spreads out its wings, it is a sign of heavy rain.

There will be rain in three hours, if a frog croaks in an open place.

If the *gryllus* croaks from a broken or leaky pot, rain is sure to fall.

If sheep flock together, there will be heavy rain.

A web in a paddy-field portends heavy rain.

The appearance of dragon-flies is the sign of good rainfall.

If ants ascend trees, fields will yield in abundance.

The next series of proverbs refers to plants supposed to afford indications of the weather. We quote as follows:—

Mangoes for a good season, tamarinds for a bad one.

Mangoes foretell famine, rose apples a good season.

When the mango yields plentifully, people suffer very much from small-pox.

Then come some proverbs relating to the nature of soils. The last of these is the following curious one:—

The soil under a fowl's foot bears ten million colours.

Mr. Benson explains this as follows:—

In No. 274, the idea conveyed is that every inch of soil varies in colour: colour is, therefore, but a poor guide to classification.

The next series of proverbs relates to tillages and general management. From Mr. Benson's remarks on these we quote the following:—

No. 275 refers to the necessity for ploughing very frequently, as, according to the untivo system, one furrow will not run immediately over another except after crossing and recrossing several times. The succeeding sayings all refer to the necessity for thorough tillage, and No. 280 alludes to the advantages of deep ploughing. No. 281 is very interesting, and refers to the three main-stays of the South Indian farmer. In No. 284, the softness of the wood, which soon makes margoosa wood wear out and the plough made of it become useless, is alluded to, and, in No. 285, the necessity for having a good leader to a string of ploughs.

The *magili* crops system, referred to in Nos. 288 and 289, may be compared to the autumn ploughing of English farming, as the chief feature of it is the breaking up of land immediately after harvest. The *egili* crops, referred to in Nos. 290 and 291, are crops that are restorative (or enriching) from the treatment they receive. The *Mālas* and *Mādigas*, or the *Pariahs*, are regarded as the lowest and least competent members of the community, as being excessively stupid; cf. Nos. 279, 288, 291 and 355.

Nos. 292—297 allude to the essential characters of after cultivation and weeding. In No. 293, the *paitisal* is a harrowing, performed usually three days after sowing, to break up and loosen the surface soil so as to hasten sprouting. The same operation is referred to in No. 249, which shows that it must not be delayed. *Garika*, the *Cyodon dactylon*, is a common weed and if not thoroughly rooted out, soon overrun the land which then becomes useless for cultivation, No. 297.

The value of manure is clearly shown in Nos. 298—301, and the manner in which it should be used in No. 302. Reference to No. 280 should again be made here. A cow trained in the native way will seldom give any milk unless her calf be present. No. 303 has its parallel in—"The feet of the sheep are golden," and shows the value attached sheep-folding. In 304, the practice of the ephphorda hiring out their sheep to manure the land of the actual cultivators is alluded to. The following are some of the proverbs alluded to:—
If land is in good tith, it will yield even to a *Pariah*.

Good tillage prevents disease;
Leaf manure gives luxuriance;
Cattle manure increases the yield.

One hoeing is equal to ten ploughings.
A field without manure is as useless as a cow without her calf.

If there be enough manure, even an idiot will be a successful farmer.

Apply cattle manure to dry land and leaf manure to wet (paddy) land.

If you manure your field with the earth thrown up by whiteants, it will be productive.

The next series of proverbs relates to crops and cropping. From Mr. Benson's remarks we quote as follows:—

The judicious adaption of crop to soil (No. 309) is well understood by the ryot, as also is the use of good seed. No. 311 refers to the practice of sprouting paddy before sowing. The necessity for sowing at the proper time (Nos. 312-316) is strongly insisted on. The benefits of early sowing are also decisively pointed out, as well as the entire dependence of the farmer on the rains, No. 320; the *kist* is the land tax.

The practice of thin sowing, alluded to in Nos. 322-328 is very generally followed on dry land. The effect of thick sowing producing straw and thin sowing grain is well pointed out in Nos. 325-27. Transplanting (No. 329) is chiefly confined to paddy and to garden crops, and with the former is by no means universally followed.

No. 333 alludes to the injury that may be done by part of the crop being unripe and so causing fermentation in the sheaf.

No. 335 insists on the advantages of having rain at any cost, whilst No. 336 refers to the injury it sometimes does if it comes immediately after sowing. As specimens of these proverbs we quote the following:—

Even in dreams, the seed should be sown in proper season.

A thin crop yields well, a thick one looks well.

Rain before the seed sown is as painful to see as the face of an enemy.

Paddy forms the subject of the next series of proverbs. Mr. Benson says:—

Nos. 365 to 389 relate solely to this crop and bring out the main points regarding the treatment of it pretty fully. Paddy does not like a poor soil, No. 365; it requires care and attention, No. 366; and land when being prepared for it should be thoroughly levelled, No. 369; and properly weeded, No. 370. The crop requires a large amount of water, Nos. 375

and 376. No. 379 is tantamount to saying "early planting should be thin, late planting thick." In Nos. 380 and 381, early sowing is shown to be valuable, and in Nos. 382 to 385 the results of late sowing to be disastrous. No. 385, alludes to the fact that such late sowings rarely come to anything. No. 362 the *chitta* (an insect), which attacks the leaves and stalks of the paddy, is believed to do the crop good, if the attack be timely, as it leads to greater vigor. In No. 387, the paddy crop is understood to be speaking: the meaning being that it becomes ripe at that time.

We quote the following:—

Will sugarcane and paddy grow on poor soil?

Watch and you have a paddy field; neglect and you have only a waste.

A paddy field without weeding is like a temple without a god.

Growing tailed paddy is like befriending a blood-sucker.

A stream for a rice field, a troop for a chief. Other crops form the subjects of the next batch of proverbs. The following are some of them—

Cholera succeeding cholera will not grow well.

The first part of a maize cob and the last part of a tobacco leaf are the best parts.

In a bad season, even red gram does not grow.

When you take up land, sow horse gram: before you relinquish it, crop it with gingelly.

An easterly wind to green-gram, and mouth disease to cattle (are injurious).

An impoverished man should sow gingelly.

Did castor cultivation ever pay well?

Ten ploughings for cotton.

If sugarcane runs crooked, it does not get bitter.

The more you press sugarcane, gingelly seed, or a *Sudra*, the better will the result be.

(Transplant) brinjals old and paddy tender.

If we touch a pumpkin it decays, and if we walk over a water-melon plant, it grows well.

Garlic is as good as ten mothers' care.

Water obtained after cleaning rice is injurious to coconut plants.

The last batch of proverbs relates to live stock. From Mr. Benson's remarks we quote as follows:—

The number of sayings on this subject is comparatively limited and they are not very comprehensive.

No. 464 alludes to the real extravagance of purchasing poor cattle. Nos. 466 to 472 give varied advice as to purchasing stock—color, horns, legs and tail, are all to be taken into account. In No. 469 the seven members are the legs, horns and neck. In No. 471, the bullock referred to is one that has been troublesome to brook in. The birth of a short-tailed, or of a blind animal in a man's herd are believed to be followed by the results noticed in No. 472 against each.

No. 473 indicates much carelessness in breeding. Nos. 478—481 allude specially to the necessity for feeding cattle well, the last mentioned alluding specially to the value of fodder given to cattle in the early morning before they go to work. The *Buttukadimi* is the *binauclea parvifolia*. No. 482 alludes to what is seldom practised, i.e., littering cattle well in their stalls. The high value set on dairy cattle is referred to in several sayings, many of which convey practical hints.—Thus No. 487 refers to the great care required by milch cattle; Nos. 488 and 489, to the necessity for feeding them well; No. 490, to the value of brooding; No. 492, to the prevailing idea that a she-buffalo will yield as much whether milked once or twice a day; Nos. 495—498, to the difficulties experienced in milking cows which have lost their calves; No. 500, to the habit of concealing the value of a milker as long as she lives; No. 502, to the practice which prevails in places of turning out the buffalo to act as the village scavenger; and No. 503, to the way in which the calf is usually half-starved. No. 504 alludes to the fact that the care of the she-buffaloes is especially the women's work. Few of the ryots' cows calve annually (No. 505), and the calves of those that do are usually puny. The belief that a cow will invariably kick (No. 506) when they are being milked leads to their legs always being tied.

Nos. 509 and 510 allude to the differences in the qualities of bullocks and he-buffaloes for draught purposes. In No. 513, the necessity for branding in exactly the right spot, being as great as that of speaking to the point, is alluded to.

The following are specimens of the proverbs:—

High-priced cloths and low-priced cattle should not be bought.

Purchase without further inquiry a bull with thin horns.

One word is enough for a good man, and one stroke for a good bullock.

A bullock without a nose-tring and a child brought up by a widow are uncontrollable.

The ploughman who works a bullock for more than ten years is sinful.

Property is the strength of man, feed that of a beast. There will be no want in a house where the churn and the spinning wheel are at work.

There are sixty-six varieties of sweetmeats in the under of the cow.

Look to the mother before you marry the daughter, milk a buffalo before you buy it.

Though a she-buffalo eat filth, will the milk be spoilt?

To keep an elephant a man requires a district; to keep a horse a village; to keep a she-buffalo a maid.

Cultivation with buffaloes is useless.

We have thus given specimens of this interesting collection; and we hope that we shall soon see in print a similar collection of the wise saws of our Ceylon agriculturists.

BRICK TEA AS CURRENCY.—Mr. Julius M. Price, the special artist of the *Illustrated London News*, in his description of his journey across Mongolia writes:—

The currency of Mongolia is peculiar, and requires much experience to understand it. On one occasion I bought some trifling article and paid for it in Russian money, which the Mongols are, at any rate, shrewd enough never to refuse. But imagine my surprise when, for the change, I was handed a small slab of brick-tea and two dirty little bits of floss silk, which I should have passed unnoticed in the gutter. These rags, which intrinsically were probably worth less than a farthing, represented twenty kopeks (sixpence), as I was informed, while the tea was equivalent to thirty kopeks. This tea, by the way, is the only real currency throughout Mongolia: the silk is becoming gradually obsolete because it wears out too soon, whereas the tea will stand almost any amount of hard wear. A "brick" of tea, sixteen inches long by eight wide and about one-and-a-half thick, represents sixty kopeks, equal to one shilling and sixpence. If a smaller sum is necessary, the brick is cut up into sections worth six or ten kopeks each, and even these are again subdivided by the poorer Mongols. It is curious to note that, although Mongolia is really Chinese territory, everything is Russian, so to speak; and even the tea and silk represent an equivalent in Russian and not Chinese money. Some of the Russian merchants in *Ourga* have even adopted a sort of private bank-note system, so as to do away with the bother of having to keep a large stock of loose cash—that is, of "brick"—always handy. These notes represent so many bricks each, and are redeemable on demand; but I hear that the Mongols prefer the bulky article to the flimsy paper substitute. When, after a time, this currency becomes injured by hard usage, and chipped round the edges, it is used for the usual purposes of tea, and it may be imagined what a delightful beverage it makes after it has been passing from hand to hand for some months among the dirty Mongols. However, these children of the desert are not fastidious, and the greasy-looking stuff is broken up and literally put to stew in the common caldron of the "yourt," where, eaten with millet seed, it makes a dish much appreciated for some days.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA IN FRANCE.—In another column we reproduce a report of the first statutory meeting of the Palais Indian Tea Houses, Limited, which was held at the registered office, under the presidency of Mr. R. B. Magor. We would call the attention of our readers to the excellent work which is being done by this company. It is with regret that we learn that this company has received but very limited support from the members of the tea industry, and that for this reason it is in contemplation of appeal for further subscriptions, either to the outside public or to the Ceylon tea growers. It would manifestly be of immense advantage to the Indian tea community to keep, more or less, in its own hands this enterprise, and utilise it for its own purposes. If it is allowed to drop into the hands merely of a circle of shareholders, who may wish to utilise it solely for profit, or into the hands of the Ceylon industry, its special *raison d'être*, namely the pushing of the interests of Indian tea only, will disappear, and it may ultimately descend, some day into a mere Congou-selling establishment, or, at any rate, altogether lose its original and much to be desired character. We urge on our readers—those who have been tardy in supporting it—to obtain a shareholder's footing in the company, either as debenture holders or as preference shareholders. The Board of the company is a thoroughly representative one, the secretary is a gentleman whose interest is altogether bound up in Indian tea planting, and should any one fail to be satisfied with what is known of the company's work, he has only to present himself at the offices of the company at 133, Leadenhall Street, to be furnished with the full information regarding the whole working of the Paris business from its commencement to the present time. Our readers will observe that the next forward movement of the company is to make a great show of Indian tea at the forthcoming Chicago Exhibition, an opportunity which, undoubtedly, should not be neglected.

LOSSES IN THE CHINA TEA TRADE.—As many importers of China tea supposed to have been losing money for years it can only be imagined that either the sums lost are not very large, or that the said importers can thrive on them. There are now rumours in the "Lanc" that further heavy losses have been made in the China tea trade. Those who know most about this business speak of £750,000 as a minimum of the amount of loss to be made up between now and the end of the year. It is quite evident that the game of losing money cannot go on forever. In the absence of any other result the present state of affairs should at least lead in some interesting information being given on the subject of "how to continue to trade on reputed losses."

CEYLON TEA SALE DAYS.—The large supplies of Ceylon tea which have recently been placed on the market have been the means of again raising the question as to whether some alteration in present arrangements could not be made for regulating supplies. A meeting of the Tea Brokers' Association is to be held today, when the question will be considered. At the last meeting of the Tea Committee of the Ceylon Association the matter was under consideration, and the following resolution was adopted:—"That a letter be addressed to the chairman of the Wholesale Tea Dealers' Association enquiring if he has any special suggestion to make on the subject, and asking if it would tend to lessen the pressure if in each week two entire days were devoted to Ceylon sales." As an instance of the large increase, it may be pointed out that the sales for the ten months of the current year have exceeded those of the same period in 1890 by 16,000,000 lb.

TEA SALES WITHOUT RESERVE.—It used to be the custom, when the words "without reserve" were printed in a catalogue, that tea was sold in the Commercial Sale Rooms, Mining Lane, to the highest bidder, but complaints, says the *Grocer*, have been freely made recently of the inconsistency of importers putting up their teas for sale with the intimation referred to, and yet either attending the public sale themselves and buying the tea to, or protecting it

by the bids of their representatives. Of course, every man has a right to do what he likes with his own. If he puts a tea up for sale by public auction in the ordinary way, and the bids do not reach the prices he wishes to obtain, no one can object to his either withdrawing the tea or making a higher bid, either directly or indirectly; but when the words "to be sold without reserve" are printed in the catalogue as an inducement to buyers to attend the sale, the buyer has a right to expect the importer or his broker will accept the highest bid, and thus fulfil one of the conditions upon which the sale is attended and an offer made. There can only be one end to such an inconvenient and irregular proceeding; buyers will abstain from attending the sales of any broker who misleads the public by having such words printed on a catalogue and does not carry them out faithfully. We can hardly think importers have fully considered the consequence of adopting such an ill-advised course, for they cannot wish to drive away their best supporters, and that they will assuredly do unless they maintain the correct principle of selling teas strictly in accordance with the terms of the catalogue. The recognised conditions of public sales are already drawn up almost entirely in favour of the seller, and require amendment in several particulars. In the interests of the importers we advise them not to provoke buyers in the manner indicated, or they may have to consider the whole subject of the public sale conditions, and this, without doubt, would not be to their ultimate advantage.

LAST WEEK'S TEA SALES.—The *Produce Markets' Review* says:—"There has been a considerable falling-off in the quantity of Indian tea brought forward, but the demand for all good grades remains steady, with a hardening tendency in some cases. Well-selected teas of any grade continue to meet with good competition, and have probably now touched the lowest point; they are in many cases cheaper than at any time last season. The excellent value offering, especially for really good liquoring sorts under 1s, is shown by the increasing consumption, and although the exports from Calcutta will probably be 8,000,000 lb. more than last year, most of this increase has already been disposed of. At the public sales 39,369 packages were offered, against about 43,000 last week, of which 3,500 were withdrawn. There was a good enquiry for all good medium and fine descriptions at steady prices, while the finest sorts fetched firm rates. About 20,000 packages of Ceylon teas were offered at Tuesday's sale, but the dealers showed little inclination to buy, except at lower prices, and a reduction of from $\frac{1}{2}$ d to $\frac{3}{4}$ d was established in common to medium teas. A strong impetus has thus been imparted to the country demand, and most of the tea sold has probably already passed into the hands of country buyers. Good teas, however, continue to be enquired for at fully late rates, and for fine liquoring Pekoes at from 10d to 1s 1d there has been increased competition. The quality of the teas shown has again been disappointing, and it is to be hoped it will improve. The arrivals for the week are:—The "Glan Sh elair," "City of Edinburgh," "Dictator," and "Scindia" from Calcutta; "Yorkshire," "Massilia," and "Glan McKinnon," from Colombo; "Sutlej" and "Gaekwar" from Calcutta and Colombo; "Keemun," from Yokohama Shanghai, Foochow, Hong Kong, and Colombo; "Glonfalloch," from Shanghai, Foochow, Hong Kong, and Cebu; and the "Radnorshire" from Hong Kong. The *Grocer* says:—"Quite a low range of prices is now being established in Indian as well as other branches of the tea trade, and the only question left undecided is whether the reduced values ruling are attributable to a deterioration in the quality or to a feeling of heaviness in the market. We are inclined to think that both these facts may be urged as a reason for the present cheapness of Indian tea, which is likely to continue so long as the plethora of supply exists, or at least until importers cease to press forward their consignments to such an extraordinary degree as they have done of late. As an outcome of the increasing pressure to sell Ceylon tea on two days of the week, it is understood that a meeting will shortly be called to consider the expediency of having different arrangements for holding public sales in the future."

THE ADULTERATION OF PRODUCE.—Tea under this category occupies much the same position as the subject-matter of the well-known chapter on "Snakes in Iceland." There is no tea adulteration now if the official report on food analysis issued by the Local Government Board may be taken as conclusive. The following shows samples of some produce examined during the year, and the percentage of cases in which adulteration was reported:—Coffee: Number of samples examined, 1,733; number of samples adulterated, 266; percentage adulterated in 1889, 14.9; percentage adulterated in 1890, 15.3. Sugar: Number of samples examined, 246; number of samples adulterated, 34; percentage adulterated in 1889, 0; percentage adulterated in 1890, 13.8. Pepper: Number of samples examined, 1,329; number of samples adulterated, 75; percentage adulterated in 1889, 5.9; percentage adulterated in 1890, 5.6. Tea: Number of samples examined, 349; number of samples adulterated, 0; percentage adulterated in 1889, 0.5; percentage adulterated in 1890, 0.0. The number of samples of coffee condemned is very high, the adulterant being almost invariably chicory, and the proportion used being often enormous. Proceedings were taken in 171 cases, and fines amounting in the aggregate to £179 were imposed. Of these, one was of £20, two of £10, two between £5 and £10, and four of £5. Of the 246 samples of sugar examined, nearly one-seventh were reported as having been coloured with an aniline dye of an amber tint in order to make white crystals of beet sugar imitate the most valuable Demerara. The quantity of the dye used however, is very minute. In the case of pepper, adulteration a few years ago was on the increase, owing to the use of ginger fibre from which the active properties had been abstracted by the ginger beer manufacturers, and which, after being dried, was ground up with peppercorns. This practice, however, seems to be now out of favour, and the percentage of samples condemned, which in 1886 was no less than 13, sank in 1890 to 5.6.

SMART.—In his monthly journal, *Night and Day*, Dr. Barnardo makes the following announcement:—"The Dalukola Tea Company will give 1d to the Homes for every pound of tea sold, the labels for which are sent to me. As a pound of tea is sold for 2s, this offer amounts to nearly 5 per cent on all sales. As I can personally bear witness to the really fine quality of this tea (every packet of which has been sealed up in Ceylon), I imagine I am doing my readers as good a service in bringing it to their notice as I shall do my Homes if a vast number of labels are forthwith returned to me by purchasers."

A SUGAR BOOM.—There is a "boom" in sugar, the price of which has advanced in Mining Lane more than £1 10s per ton. The advance has been established without the excitement which has characterised similar movements of past years, and has been due, not to the unreasonable fears of bear operators, but to the steadily-growing conviction that without the check of enhanced values, consumption will more than absorb the world's supply. Year by year the production of sugar has been on a more gigantic scale, but this year the crop of beet sugar—the basis of speculation—is stated to be seriously deficient.—*H. and C. Mail*, Nov. 20.

A POSSIBLE COALFIELD NEAR MADRAS.

Twenty years ago Mr. R. Bruce Foote, late of the Geological Survey of India, in company with Messrs. O. A. Oldham and W. King also of the Geological Survey, examined and mapped geologically the District in the neighbourhood of Madras, and published the results in the "Memoirs of the Geological Survey of India" Vol. X., Part I. At that time certain plant beds were indentified as corresponding with the Rajmahal Series of the Upper Gondwana system, but owing to the very level nature of the country, and the difficulty of obtaining sections, it was impossible to say positively what formation lay next below these plant beds. It was however, supposed that the Lower Gondwanas,

the formation in which nearly all the coal seams are found in India, might possibly be found at some depth below. Now, after a lapse of twenty years it has been proved beyond all doubt that the Lower Gondwanas are present and the discovery is due to the enterprise and perseverance of the Rev. S. Dominic, a priest of the Roman Catholic Church, in sinking an artesian boring with the object of obtaining a permanent supply of water. This boring he commenced so far back as April 1886, but owing to various interruptions of the work, it was not sunk further than 272 feet by last May. In that month Mr. Bruce Foote went at Father Dominic's invitation, to inspect the boring which is situated in Place's Gardens, in the Conjevoram taluq of the Chingleput District, and to give his advice on the prospects of the boring. The results of the inspection were published at the end of last August in a Government Order on Mr. Bruce Foote's report, which we publish in another column. The opinion there expressed by Mr. Bruce Foote does not appear to have impressed the Madras Government much, although it sanctioned an additional grant of £500 to Father Dominic for carrying the boring down to a greater depth. Two gentlemen in Madras, however, considered the subject of such enormous importance that they immediately paid a visit to Place's Gardens, carefully inspected the specimens raised from the lowest parts of the boring, and have since obtained regular information in regard to the further indications displayed by its progress downward. The boring as now reached a depth of 286 feet, the last 21 feet being pieced with a bed of black clay, which has become steadily richer in bitumen, and under which there are fair reasons for hoping that a coal seam may be met. In the meanwhile a more detailed report has, we understand, been obtained from Mr. Bruce Foote, who has expressed, in even more decided terms, his opinion that an extensive coal field will probably be found under, or in the neighbourhood of Place's Gardens, Messrs. Leighton and Co., who have the matter in hand, after obtaining Mr. Bruce Foote's advice as to what lands to select, have lost no time in applying to Government for prospecting rights over a large tract, and they have received assurances from the Madras Government that it will do everything in its power to expedite the work of proving whether coal is to be had there or not. A Company, to be called The Arcanum Coal Company, Limited, is already in course of formation, and it is intended to raise capital in the first place to search for coal seams by means of steam boring machinery.—*M. Mail*, Nov. 18th.

[If coal is found near Madras there may yet be hope for coal in Ceylon.—*Ed. T. A.*]

PALAIS INDIEN TEA HOUSES.

The statutory general meeting of the Palais Indien Tea Houses, Limited, was held on Friday at the offices of the company, Rochester Buildings, 138, Leadenhall Street, E. C., Mr. R. B. Major in the chair.

The Secretary (Mr. E. A. Roberts) read the notice convening the meeting.

The Chairman said:—Gentlemen,—As this is merely the statutory meeting, there are no accounts to submit to you. But as it was thought possible there might be some shareholders present who would like to have some information about the progress of the company, and what it has been doing, a few facts and figures have been prepared, which I will submit to you. The origin of the business is familiar to you. The Indian tea importers subscribed the sum of £3,000 to bring forward their products at the Paris Exhibition, 1889. Owing to the very large sum that had to be paid to the British Commission and the unenviable situation of the Indian Palace, it was found that if the committee had withdrawn from Paris at the close of the Exhibition most of the money would have been expended without any pronounced advantage to the tea industry, and any effect that might have been produced in the minds of the French people with re-

gard to the advantages of tea-drinking or the merits of Indian tea would have soon disappeared. The committee therefore wisely resolved to find a little more money, and continue the work in Paris in the hope of recovering at some future date some portion of the outlay. With this in view, a house for the sale of dry Indian teas was opened at 204, Rue de Rivoli. From the experience of the Associated Tea Planters in America it was felt that this alone would not lead to very satisfactory results. It was necessary to reach the tea-drinking public, and no simpler way of doing this could be devised than to continue in outside permanent establishments the work that had been commenced in the Indian Palace. Tea rooms were, therefore, fitted up in the Indian style in the most frequented parts of the city at which pure Indian tea is sold in cup and in packets. The first of these places was only opened on November 25, 1890, almost a year ago, the second in the end of April, and the third in the month of May this year. At this stage the present company was formed. It was thought that the business had sufficiently developed to warrant the enterprise being taken over by those who had hitherto found the bulk of the capital, so that, as it became lucrative, their previous outlay might be recouped. A prospectus was issued in July last, and a scheme arranged under which the previous guarantors mainly found the additional capital necessary for present requirements in Paris. Owing to the short time the branches have been opened it will be seen that opinions as to ultimate success must be more or less speculative. Nevertheless, the time that has passed does much to warrant an opinion being formed. The two first tea-rooms are in the best part of Paris, one near the Opera House and the other in the Avenue des Champs Elysées. They are most conveniently situated for that portion of the French people that have been, even in a small way, accustomed to drink tea. From the moment the doors were opened these establishments received a considerable amount of support. It was evident that they met a want which had been felt. In each, Indian tea is served in a separate pot, with milk and sugar, for half-a-franc (say 4d), and the service is much better than anything of the kind in England. The company took over the business in the midst of the holiday season, when everyone who can afford to do so leaves Paris for about two months. During that period the returns fell off, but they did not sink to a lower point than might fairly have been expected, and with this exception the progress has been continuous from the time each house was opened. It is most satisfactory, therefore, for us to be able to report that at the moment the holiday makers came back the returns at once increased practically to the highest level they had even reached. Now every week and month shows such satisfactory progress that it seems probable that each of these places will be paying within three or four months. As refreshment houses of this nature cannot be expected to make a good return on the day they are opened, probably this is as good a result as could be anywhere achieved. The committee felt that their work in Paris would not be satisfactory if they did not break new ground and try to develop a taste for tea amongst a portion of the population not yet accustomed to drink it. It was with this end in view that the third premises were taken. They are more in the east of Paris, situated in the Boulevard Bonne Nouvelle, nearly opposite the Lycée, and in the neighbourhood of some of the large theatres. This place also is showing steady progress, and as the premises are most advantageously situated, there is every reason to hope that in a little time they will be as satisfactory as the others. Probably these three establishments are the only places in which one is sure of getting a drink of pure Indian tea. Nothing else is supplied in restaurants. Although we consider it advisable to keep other kinds of dry tea, especially Ceylon, in stock, the total sales are over 90 per cent Indian. Every opportunity is taken to attract attention to Indian teas. Since the great exhibition, where a gold and silver medal were

obtained, two other medals have been gained. This year there was a very interesting exhibition opened in the Champs Elysées in the month of August, which remains open till the end of November. The company were offered a large salon here, rent free, subject to a moderate commission on their takings, and in this room an increasing business has been done. In August 800 persons were served there, in September 950, and in October 1,586, showing a satisfactory increase. A business of this nature requires more capital than shops in which dry tea only is served. Suitable fittings and furniture must be provided, and the best situations must be secured, all of which cost a good deal of money. Probably there will be no difficulty in finding of the money that will be required for extension from time to time, if it can be shown that a fair return will be made. The figures that are at our disposal up to the present are, of course, not conclusive; nevertheless, I think they will be regarded as satisfactory. Our total sales in the year 1889 was over 16,000 francs, in 1890 over 30,000 francs, and in 1891 (estimating the two last months of the year on the basis of the others) they will be over 120,000 francs. Seeing that two of the places have only been opened since May, it is fair to anticipate that next year will see a very considerable, if not quite proportionate increase. There is the strictest supervision from the London offices of the company, where daily returns are received. The directors feel that these facts should be sufficient to satisfy the shareholders. It will be asked, "What is to be our future progress?" There is no intention at present to open more branches in Paris. Efforts will be concentrated to improve those already going. There is a strong feeling, however, that something should be done in other quarters. A favourable space for buildings at the Chicago Exhibition has been practically secured, and seeing that the consumption of tea there is about 1½ lb. per head of the population against about ½ oz. in France, good results will probably attend an energetic effort made in the same judicious manner. If the resources of the company admit it the directors would consider the practicability of opening similar branches in other parts of Europe. Possibly good prospects also await such attempts in Nice, Milan, Vienna, and Berlin. There can be no doubt but that the work of opening new markets becomes more important year by year. In the face of the large estimate of the present crop and the low London prices, together with the annually increasing yield, I think that even the busiest should be willing to spare a few moments to consider whether the organisation that is furnished by the Palais Indien Tea Houses Limited, is not one that would pay all those who are interested in Indian tea to support.

Mr. Bullock (chairman of the Upper Assam and Assam Frontier Companies) referred to a visit he had paid to the company's branches in Paris, and expressed a desire that only Indian tea should be sold at them.

Mr. Seton wished to point out, in case there might be any misconception about what Mr. Bullock had said, that the question of a certain admixture of other teas with Indian tea in the first place had been frequently before the Board. The matter had been fully discussed and it was not without a full knowledge of all the aspects of the question that what had been referred to had taken place. Quite recently, however, the Board feeling that there had been a great deal of criticism about the tea sold not being all Indian tea, called for special reports on the subject of the respective quantities of Indian and other teas sold and they were pleased to find from those reports that the tea sold, other than Indian, constituted a very small proportion indeed—only one per cent.

Mr. Thomas Longh said that in the course of a few months Mr. Bullock's wishes would be carried into effect. There were several practical difficulties to deal with, but the board had taken steps to obtain the end desired.

After some further discussion, the proceedings concluded with a vote of thanks to the chairman, proposed by Mr. Bullock and seconded by Mr. Seton.—*H. and C. Mail*, Nov. 20.

LARGE PIECES OF AMBERGRIS.

The exceedingly high prices (equal to fully three times the weight in gold of the drug) which perfumers have been compelled to pay for the finest ambergris lately is the best proof of the indispensability of the drug in the preparation of high-class perfumes. For over a year the price of the best ambergris has now ranged from 180s. to 200s. per oz., and until quite lately there did not seem to be any prospect of an early fall in prices. The small compass within which a very valuable quantity of the drug may be imported without attracting attention, and the ease with which the requirements of the Customs regulations that all goods imported shall be entered under their proper name and at their full value may be circumvented, where it is deemed advisable to keep quiet concerning a consignment of ambergris, render it exceedingly difficult to follow closely the imports of the drug. It is stated, for instance, that although for many months fine ambergris has been thought to be exceedingly scarce in our market—and the visible supply has been so in reality—there has been a far greater supply available than has appeared on the surface. Under these circumstances, the recent importation, to which we drew attention in our trade report, of a piece of ambergris from Melbourne weighing, it is said, 136 lb., and valued at 10,000l., naturally caused a good deal of excitement. The piece is believed to be the same which was captured by a black man in Tasmania some time ago, and of which we gave a description. But the matter still remains shrouded in some mystery, for the London consignees of the parcel refuse to show the piece to anyone, and even decline to give the slightest information of any value. Whether this policy is a wise one or not is an arguable question; it is certain, however, that the mysteriousness of the consignees has not assisted in allaying the fears of a heavy fall in the price of the drug that were the natural outcome of the announcement of the large importation. It may be presumed, however, that the consignees will want to dispose of the drug, and it is certain that they will not be able to do so without showing their hand.

The historical references to ambergris have recently been enriched by the publication, under the auspices of the Hakluyt Society, of the account of the voyages of François Leguat, a French Huguenot, to the isles of Rodriguez and Mauritius, Java, and the Cape of Good Hope. The Sieur Leguat's voyages were made during the years 1691 and 1698, and in his narrative frequent references are found to the precious perfume. He states that it occurs plentifully on the shores of Mauritius, as well as of the island now known as Reunion, in the Indian Ocean, due east of Madagascar, and also on those of the little island of Rodriguez, in the same latitude, where, to quote his words, "the sea brings up yellow amber and ambergreen." The word "ambergris" (grey amber) was, in fact, given to the substance expressly to distinguish it from the ordinary or yellow amber. Possibly both were believed to be of common or allied origin. Ambergris has been a prized and costly luxury for centuries, though the Sieur Leguat does not appear to have been quite alive to the value of the drug until taught by bitter experience. At Rodriguez he found a large piece of the substance, and carried it along as a curiosity, not knowing the true importance of the find. That piece of ambergris wrought its discoverer cruel misfortune. It weighed about 6 lb. and as Leguat's party no longer cared to carry it, they disposed of it for a trifle to a Dutch artisan of the island, which was then a Dutch colony. The colonists were stringently for-

bidden to own or trade in the commodity, which was a monopoly of the Dutch Trading Company, who forwarded to Batavia all the ambergris found on its outlying stations, and from that port shipped the drug to Holland for sale. When the Governor of Rodriguez learnt that Leguat's party had traded in the substance, he seized all their belongings, and finally banished them to a barren island rock, where they suffered great hardships. In the "London Price Current of Colonial Produce" of 1777, which we reproduced in facsimile last year, ambergris is quoted at 40s. to 45s. per oz. troy for "gray fioc," while Irish amber, obtained on the Atlantic coasts of the Emerald Isle, was valued at 25s. per oz. Considering the respective purchasing powers of money two centuries ago and at the present day, these prices are quite equal to the average value of ambergris in recent years.

So plentiful was ambergris on the shores of the islands in the Indian Ocean in the seventeenth and eighteenth centuries that some islets off the north-east coast of Mauritius became known as the "Isles d'ambre." Ambergris was also found in the Japanese waters; and the Dutch traders not only kept Europe supplied with it from their emporium in Batavia, but also imported it into the dominions of the various Eastern potentates with whom they came into contact. A piece almost rivalling the latest giant find was imported from Batavia into Madras in 1699, and is described in contemporary chronicles as a "very stately piece of Ambergreese, upwards of 800 oz." On the Madras islands, again, west of Ceylon, ambergris, according to another seventeenth century-traveller was more plentiful than in any other part of the Indies. Any of it found on shore had to be delivered up to the king, the penalty for failing to comply with this order being the cutting-off of the culprit's hand.

In the writings of earlier travellers references to ambergris are also by no means infrequent. Zanzibar was famous for its ambergris from before the time of Marco Polo. But there is no need to hark back to the half-forgotten worthies who made history in the Indies centuries ago for accounts of gigantic pieces of the valuable drug. It is true that the largest single piece recorded in history as an authentic find (it weighed 182 lb.) was one purchased from the King of Tydore by the Dutch East India Company nearly two centuries ago, but from America stories have since come of pieces many times heavier than that of the King of Tydore's. It is only fair to say, however, that these American stories have never been backed by trustworthy evidence. Hence the account of the find, in the year 1853, by the schooner "Watchman," of Nantucket, of 640 lb. of ambergris in a whale floating on the high seas, with the stories of a 560-lb. piece brought home by an American whaler in 1886, of a 266-lb. trophy captured by a New Bedford whaler, and of a 130-lb. piece taken out of a whale near the Windward Islands, may be dismissed as "not proven"; and the mass of detail with which some of these accounts are embellished may fairly be regarded as having been added simply "to lend artistic verisimilitude to a bold and unconvincing narrative," as Mr. Gilbert has it.

It is a fact, however, that in 1882 a piece of ambergris weighing 12 lb., and found in a gravel-pit in New Zealand, was sold in the London market. It realised an average price of about 85s. per oz. There is also a story current that a well-known Micing Lane broker was instructed some years ago to sell "a barrelful" of ambergris which had been for many years in the unappreciated possession of a gentleman who was altogether unaware

* Maldive!—Ed. T. A.

of the nature of the substance of which he was the fortunate owner. The harroful proved to be ambergris of very fair commercial quality, and was disposed of with careful management, at the full market value of the day, the broker wisely never binting to anyone until the last piece was sold how great was the quantity entrusted to his care, for fear of spoiling the market.

The greater part of the ambergris sold in London during the last few years has been that obtained by the New Zealand and Tasmanian whalers who ply their trade in the Antarctic Ocean. Whaling was once an important industry in Tasmania, and quite a large fleet of whalers was owned by Hobart firms. Now the Tasmanian industry has practically ceased to exist, and there is no hope of its revival. New Zealand still possesses fisheries of some importance, and will probably continue to supply our market with much of its ambergris for many years to come. Meanwhile spermaceti whales are getting scarcer year by year, and the time may soon come when the scarcity of ambergris shall be chronic instead of spasmodic. It is to be hoped that before that date science will have taught us how to supplant nature in the production of ambergris; but at present there are no indication whatever of an efficient synthetic substitute—*Chemist and Druggist.*

NOTES ON POPULAR SCIENCE.

By DR. J. E. TAYLOR, F.R.S., F.G.S., &c.,
EDITOR OF "SCIENCE GOSSIP."

Professor Bailey, an American botanist, has been reporting on the experiments recently made at the station connected with Cornell University with electricity. Professor Lodge, one of our own most eminent scientists, some years ago showed that the electric light dispelled fog. A report on fog just published demonstrates how injurious it is to plant healthiness. Hence, if we can dispel fog, and at the same time stimulate the growth of plants by electricity, the latter will be doubly useful. Professor Bailey's experiments were made during January, February, and March, one forcing-house being exposed to the normal light of the sky during daytime, and illuminated by electricity at night. Another forcing-house containing the same kind of plants, was not lit at night. The difference in the results was so marked that the experiments have been continued this year with a view to noting the effects on colour.

Two distinguished French chemists have just read a paper before the Paris Academy of Sciences on the "Proper Odour of Earth." Everybody in the country is well acquainted with the delicious smell the earth yields after a shower of rain. This is now found to be due to an organic compound of the aromatic family. Its odour is very penetrating, and analogous to that of camphor. Its proportion in the soil is, however, only a few millionths of a grain—indeed, one three-millionth gives a decided smell. The new principle is neither acid, alkali, nor a normal aldehyde. Its concentrated aqueous solutions may be precipitated by carbonate of potassium with the production of a resinous ring. When heated with potash, an acid odour analogous to that of the resin of aldehyde is developed. Under certain conditions, such as by the employment of potash and iodine, iodiform is produced. This property is common to many other substances, but alcohol, acetone, &c., were not found during the experiments just mentioned, although some chemists state they have been met with in vegetable mould.

Here is good news for potato growers. It has long been known that a solution of sulphate of copper checked mildew in vines, and an experienced French agricultural chemist determined to try the effects on the allied species of fungus which causes potato disease. He has been trying it on the potato plants for two summers past, and has recently published a

lengthy statement of the experiments, which are of a very remarkable character. He shows that an application of sulphate of copper not only checks the ravages of the disease, but vastly increases the crop—in some instances to the extra value of £5 an acre.

The fascinating and important problem as to the acquisition of nitrogen from the atmosphere by plants is still occupying the attention of chemists, both in this country, America, and France. In the United States two eminent investigators have arrived at the conclusion that atmospheric nitrogen is undoubtedly acquired during the growth of peas and alfalfa, and that the amount of nitrogen gained increases with the number of root tubercles. Further, that the addition of soil-infusion is not necessary for the production of root-tubercles—a fact which may be accounted for by supposing that the micro-organisms or their spores exist in the air, and are deposited in the pots where the plants grow. Cereals do not, as a rule, manifest the power of acquiring the nitrogen from the atmosphere, nor are root-tubercles formed on them, as in the case of leguminous plants. The latter fact disproves the statement recently made by a French agricultural chemist, that cereals have the power of absorbing atmospheric nitrogen. Professor Gilbert has also arrived at the conclusion that free nitrogen is fixed in the course of the development of the organisms within the nodules, and that the resulting nitrogenous compounds are absorbed and utilized by such leguminous host-plants as the common red clover.

Dr. John Murray has read another paper before the Royal Society of Edinburgh on the much-disputed subject of silica and siliceous formations in modern seas. The facts are of great interest to geologists generally. There is great difficulty in accounting for the number of organisms which secrete silicic acid, and for the remains of such organisms which occur in and on the bed of the ocean. The amount of silicic acid which exists in solution in sea-water is far too small to account for the immense development of such organisms in various parts of the ocean. Dr. Murray and Mr. Irvine have proved that clay and mud carried down by rivers to the sea are to be found in even the least disturbed parts of the ocean. Diatoms can extract from these clays sufficient material for the formation of their flinty shells.—*Australasian.*

HOW TO SET A HEN.

It may seem to be an easy matter to many to do this seemingly simple piece of work, but it is indeed a thing that requires forethought, experience and great care. To set a hen so as to secure best results is indeed no child's play. In the first place, be sure your hen wants to sit. Then be sure she is in a good location; if not, move her to one. If she can be set on the ground, you will find it to be the very place; if not, out a sod, turn it over, scoop out a dish like place, then put the sod in a box, grass side down. A nest made in this way will hold moisture—one of the reasons why a hen sitting on the ground always hatches better than when up in a building. Sprinkle a little litter over the nest and put in your eggs. Always have the nest arranged so that the hen can walk on and not fly down upon the eggs. If you breed, the heavy varieties the best nest can be made by turning down a barrel with only one head out and scooping out a place in the ground so the barrel may be sunk in the ground a little. The hens can then walk on their eggs without danger of breakage. The ground will help to secure moisture for the eggs, and you can close the open end of the barrel every night, preventing rats from interfering. Take the hen off every day or two to give the eggs an airing, if the hen does not go off on her own account.

Be sure and set your hens in such a way that others cannot interfere. Mark the eggs, so that if others lay with the hen you can remove the fresh ones. After a week, test the eggs to see which are fertile and which are not. It is not your policy to have in the nest eggs that will not hatch. After removing the unfruitful eggs you can replace them with fresh ones, marked, and upon the first ones hatching, the

others can be placed under other hens. Always set two or more hens at the same time when possible, that the chicks may all be placed with one of the hens and the other set over. This saves in the way of two mothers for a few chickens. If your hens are sitting high off the ground, where moisture is not sufficient, sprinkle the eggs daily for a week before. A day or two before hatching take a bucket of water, heated to about one hundred degrees, place the eggs in and let them remain for some five minutes. This will soften the shells and inside covering and the chicks can come out of the shells with greater ease. Oh, yes, it is no trouble to set her, but you always find that the persons who take the most pains with their sitting hens always raise the most chickens.

COCONUT TOFFY—Boil one pound of white sugar and two gills of water together, while boiling stir in two ounces of butter. Boil until it will pull between the fingers, add three ounces of grated coconut; pour out to cool, mark in squares.

FROM the annual report of the East Java Agricultural Company, it appears that the crop of coffee has been small and would not cover the cost of production. The profit and loss account closes with a deficit of f. 88,982. Notwithstanding, the reports regarding the condition of the estates are satisfactory. The next year will not answer the high expectations which were formed, and the crop will not be more than about 3,000 piculs. Although the prices made are not unfavourable, the quantity is too small to compensate for the loss. The president further informed the shareholders that, according to a telegram, a fire has broken out on one of the estates, causing considerable damage to the crop, and only the quantity harvested was insured.—*L. and C. Express.*

GERMAN EAST AFRICAN PRODUCE.—The German East African Company and its kindred associations are proceeding energetically with their work of developing the natural resources of their territory. Following the example of their British fellow-organisation in securing the services of a practical Ceylon planter to superintend its new culture, the German East African Plantation Company have engaged a Mr. John Schroeder, an experienced Sumatra tobacco-planter, as export adviser for their cultures. Mr. Schroeder has already commenced his duties and pronounced himself exceedingly satisfied with the produce and the capacities of the Lewa plantations. The German East African Company have been so unfortunate as to lose the services of their plantation-manager, Dr. Hindorf, who has had to resign through ill-health. A successor to that gentleman will be appointed shortly. Dr. Peters, who is now commissioner in the Kilima-njaro district, reports that he is busy with plantation work, and has attained excellent results already.—*Chemist and Druggist*, Nov. 14th.

CINCHONA IN JAVA.—The report by Mr. van Romunde, director of the Government cinchona enterprise in Java, for the third quarter of 1891 states that with the exception of a couple of showers in the latter part of the quarter the three months had been practically rainless. Night frosts were experienced, though in small degree, in places lower than any that have hitherto suffered; but the damage done was trifling. The severe and continuous drought of the quarter caused considerable mortality among the plants put out during March and April of this year, in spite of the grounds having been kept moist by working the soil. This operation was also carried out systematically in those gardens where it had not already been done in the second quarter. On the setting in of the rain, therefore, a vigorous growth of the plants is expected. Of the crop of 1891 some 450,000 half-kilograms of bark were gathered, of which by the end of September 348,272 pounds had been despatched to

Tandjong Priok. The crop of the last few months consisted chiefly of shavings from typical ledgerianas, obtained by the scraping of second and third stems and thick branches. The object of this method of harvesting was not simply nor chiefly to obtain bark, but the formation of single-stemmed trees and the prevention of the caterpillar plague by the sparing of the crowns. For it has been found that by means of a thickly grown plantation the increase of the insects is greatly hindered. The fact is worthy of notice, that the bark obtained by the scraping of second and third stems and branches showed a mean yield of some 10 per cent sulphate of quinine, and that by this harvest of shavings about 200,000 half kilos of bark will be obtained. On 10th July and 3d Sept. sales of bark of the crop of 1890 were held in Amsterdam. The unit price for manufacturers' bark amounted at these two sales respectively to 6½ and 6 cents. At the end of the quarter there were 3,664,000 trees in the Government gardens, viz:—In the nurseries—440,000 ledgeriana (including 50,000 grafts) and 448,000 succirubra—total 888,000. In the open—2,109,000 ledgeriana (including 270,000 grafts and cuttings and exclusive of the 3,000 more or less original ledgerianas), 2,200 calsaya and hasskariana, 621,000 succirubra and caloptera, 47,900 officialis, and 1,500 lancifolia—total 2,781,600.

CINCHONA SAMPLING IN AMSTERDAM.—The *Chemist and Druggist* of Nov. 14th says:—It is well known that for a long time the method of sampling cinchona in Amsterdam has failed to give general satisfaction. The plan hitherto followed has been to allow the analysts appointed by the importers and the agents of the buyers to take against payment each a sample of bark from every bale of a certain parcel. Experience has shown that the analyses of the samples are not only often at variance with that of the bulk of the parcel, but absolute, or even approximate, accord in the results obtained from any one parcel by various analysts is exceedingly rare. This unsatisfactory result probably arises from the fact that the samples are always taken from the top of the bale only, whereas the contents of the packages are made up of parts of various trees, differing in alkaloidal contents. In order to remedy these drawbacks a meeting of gentlemen interested in the subject was held in Amsterdam on October 30th, under the auspices of the Kina-Etablissement or cinchona warehouse. Mr. Gustav Briegleb presided, and there was a full attendance. After some discussion it was decided, practically unanimously, to adopt a fresh system of sampling manufacturing barks. The Kina-Etablissement will provide, at an estimated cost of from 400l to 500l, a 3 or 4 h. p. steam engine, mills and other plant required for drawing samples on the new system. Importers and merchants are still to be allowed, if they like to draw samples on the old plan, but it is thought that few, if any of them will do so. Under the new scheme the samples will be drawn by special instruments from every part of each bale forming a parcel. The whole of this sample will be ground to powder, and a 150 grammo (about 5 oz.) sample of this will be furnished to each applicant. The cost of the new method of sampling to the Kina-Etablissement is computed at about 8l per bale, and to defray this the importers will pay 2d per bale sampled and a charge of 2d per 5 oz. sample will be made to all applicants. The quinine manufacturers declared their approval of the scheme except the agent of the Frankfort works, who announced his intention to adhere to the old method. The Brunswick works stated that they would require samples unground as well as ground.

INJURY TO THE GOOD NAME OF CEYLON TEA.

With depressing shame and bitter indignation, we attract attention to the truly shocking and disgraceful condition of things in regard to our tea enterprise, of the high character of which we were until recently so proud, contained in Mr. John Ferguson's letter "From the Metropolis." That tea, properly plucked and as carefully as possible prepared, should suffer from meteorological conditions and be inferior in quality to the high standard once enjoyed by our teas, is a matter for regret, but not a cause of shame or an occasion for censure. But what are we to say to the unprincipled enemies of Ceylon and its best interests who have managed to creep in amongst an honourable body of men and who have been guilty of the gross iniquity of deliberately sending into the market, as Ceylon tea, trash only fit for the dungbill, consisting of old leaves, twigs, and not contented with that, earthy dirt! What was called Ceylon tea has, to our ineffable injury and disgrace been condemned by the customs authorities as unfit for human food and how much better can the rubbish have been which sold in Mining Lane down to a penny per pound. When the husbandman found tares in his field, he was justified in saying, "An enemy hath done this." Equally legitimate is such language applied to the persons who prepared and those who sent into the London market, the abominable trash described by the absent editor. Typical specimens of inferior teas, sent to us by Messrs. Gow, Wilson & Stanton, can be seen at the *Observer* Office, and we only regret that specimens of the old leaves, twigs and dirt were not also sent out. The time has surely come when the names of the wrong-doers should be published and for measures being taken to prevent the despatch from our shores in the future of stuff which can yield no profit to the exporters, but which is calculated most seriously to injure a great enterprise, on which the fortunes of the colony as well as of the mass of honourable men engaged in it so largely depend. If, as is indicated, the rubbish complained of was exposed for sale at Colombo, surely there was a failure of duty amongst members of the Tea Association?

FROM THE METROPOLIS.

CEYLON TEA IN THE LONDON MARKET.

Nov. 20th, 1891.

I have been this week more than once with Mr. Stanton of Messrs. Gow, Wilson & Stanton (the well-known brokers) arranging for a very much fuller telegraphic message each week, by a new code, respecting Ceylon tea; and during these visits to Rood Lane, as well as others to the adjacent Mining and Philpot Lanes, I have been much distressed to have indubitable evidence presented to me by the brokers and by such firms as Messrs. Anderson Brothers and others of the really deplorable character of some of the teas sent over from Ceylon to London this year. I need not refer to the published lists of late when sales at 6s. 5d and even less carry their own tale and must read a wholesome lesson; for, of course such prices must mean a downright loss to those concerned in preparing and shipping them. But I have actually seen samples of "Ceylon tea" sold at 3d, 2d and dust at 1d, and have had to hang my head in dismay before the absolute trash liquored for my conviction in the brokers' offices. To think

that we who have been proclaiming the absolute purity and good quality of Ceylon, as contrasted with dirty, adulterated China teas, should have proof given that Ceylon tea planters or shippers are capable of sending over to London, parcels unworthy of the name of tea, in some cases made up of twigs and big tea leaves (not flush) and even—mixed with foreign earthy matter—even dirt. Some of the worst, I am told, are teas sold in Colombo (at the weekly auction) and re-shipped. If so, surely a remedy can be applied by the Chamber of Commerce and Planters' Association? Something must be done; for, (tell it not in Gath, publish it not in the streets of Aekelon, but) it cannot be too soon known by these bodies and Ceylon planters generally that one parcel of so-called "Ceylon tea" sold in the Lane, has been refused delivery by the Customs authorities, as being unfit for human food. Now this we must hope is a climax to be reached only once in our history as a tea-producing country. But to ensure no repetition of an act which almost amount to a crime against the good name of Ceylon, it is absolutely necessary that public opinion through the two representative planting and mercantile bodies should be brought to bear on such offences. I know nothing of names in the case; but if there is a repetition, it must be a necessity forced on Ceylon-London journalists to get full particulars and to publish them. Perhaps the Ceylon-London Association Tea Committee may take some steps; but certainly the Kandy P. A. should not wait for this, but make some move of its own. Excuse can be made for tea being occasionally injured in the course of preparation—bad withering, an error in rolling, fermentation, or even drying; but there is no excuse for preparing twigs, big leaves of tea bushes or for allowing earthy matter to get mixed with tea; for packing and shipping trash condemned as unfit for human food. As matters stand, I (and others) will be afraid to open our mouths as we have been doing in Venice, Vienna, Prague, Karlsbad, Munich and a host of other places about the purity of Ceylon teas. Some of the county dealers in England have even been returning purchases made on their account as unsaleable, and others writing sneeringly, that it is a good thing for Ceylon that they don't sell such teas unblended.

I have asked that certain samples of teas that never ought to have left Colombo should be sent out to be shown at the *Observer* office to any interested, and perhaps circulated through the the Port offices. The news I got yesterday in the Lane is that some were poor, if not bad, teas may be looked for from wet districts, consequently perhaps, on the heavy burst of north east monsoon. But all allowance can be made for this cause of hurried imperfect preparation; but not for the admixture of foreign substances, twigs and absolute dust. Let us trust that the comparatively good prices offering for fine teas will make all planters careful to see that their "plucking" is looked after; for even now there is an indisputable absence of much of the really good high-class teas that first gave a name to Ceylon. I heard of a buyer at Tuesday's sale who wanted "a tippy parcel of tea" for a special market (the South America) and who could find only one in the sale with a value properly at about 1s 5s, but for which he had to pay over 1s 8d, because the quality was in such poor supply. This ought not to be.

It is gratifying to learn of new markets opening like those in South America as well as North America. In one case of a dealer in a North American coast town to whom Messrs. Gow, Wilson, & Stanton sent a trial chest of Ceylon tea, he has responded with an order which has

doubled in quantity each time it has come until the latest one was for 100 chests. For Russia too, the demand through London for Ceylon tea is very steadily bettering. Much can no doubt be done to advertise our tea at the Chicago Exhibition if gone about in the right way, and in this connection it is of interest to read the speech of the Secretary to the Society of Arts at the opening meeting two nights ago. I quote as follows:—

The Attorney-General (Sir Richard Webster, M.P.), chairman of the council, last night delivered the opening address of the hundred and thirty-eighth session of the Society for the Encouragement of Arts, Manufactures, and Commerce at their rooms, in John-street, Adelphi. The Queen had appointed the president, vice-president, and council of the Society of Arts a Royal Commission for the International Exposition at Chicago in 1893, and he appealed to the members to justify the selection. The founders of the Society of Arts, or those who controlled its operations during the earliest periods of its existence, were the inventors of industrial exhibitions, and the council were fully qualified to secure efficient representation of British interests at the coming exhibition. It was most important that the manufactures and art productions of the United Kingdom should be worthily represented. Jackson Park, in which the exhibition to be held was almost as large as Hyde Park, and the whole of its area would be devoted to buildings appropriated to the various sections. No doubt the Chicago Exposition would be a great success, but he looked forward to another international exhibition in the metropolis in a few years, which should eclipse the American and every other display of the kind. (Cheers.) Our great Indian Empire and the British colonies would all show up well, and England must make a supreme effort to sustain its high prestige. (Cheers.) The Attorney-General then presented the medals to those who had rendered distinguished service to the society and its members by the merit of those papers read during the last session, and the usual complimentary votes concluded the meeting.

You will doubtless have had some particulars of the meeting of tea dealers, brokers, &c., at the Ceylon room on the 11th to consider the need of some further means of accommodating the sales of increasing quantities of our teas. I did not hear of the meeting from Mr. Leake, when I saw him on the 7th, or I should gladly have been present, if only to look on the men dealing and interested in our produce: better luck next time, as Messrs. Gow, Wilson & Stanton will keep me apprized of any tea business or gatherings of interest. Buyers complain of the short time often allowed to draw and test samples before Tuesday's sale to which all Ceylon agents, &c., wish to send their teas. It is true that nominally, Ceylon teas may be offered on Thursday, after the Indian teas; but, as a rule, there is seldom time and still less chance of doing justice then. The remedy is to have a separate room for Ceylon teas, and two clear days for the sales each week. There may be disadvantages though, and in any case the change is not one to be made without deliberation and the full consent of buyers or dealers, brokers, &c.

THE GREAT LOSSES IN CHINA TEA form one topic of City conversation at present. Our friends in Philpot Lane were making a calculation of the totals some days ago, and one of the partners worked the total out at £800,000 for the present season to London buyers. How near he was may be seen from the following extract which appeared in a daily, a few days after:—[Cannot find paragraph at last moment, but it gave the losses at £750,000.]

I regret to learn through Mrs. Alex. Ross that bad news has arrived concerning our

good friend and old colonist Mr. Arthur Sinclair, one of the Commissioners to Peru. While Mr. Ross, with his spare, lithé figure, kept his health in crossing the higher passes of the Andes, Mr. Sinclair being much stouter and heavier seems to have suffered a good deal—liver and heart got affected and in place of riding, he had to be carried. The latest news as I gather is that he was at a point close to the Amazon and hoped to get down the river by steamer, but was not yet well enough to travel. Mr. Ross, I gather, had to return to the West Coast again. I earnestly trust that Mr. Sinclair may soon be enabled to start and that both Commissioners may return in safety. Mr. Clarke of the Peradeniya Gardens has already come back, bringing various articles of interest, a sight of which I am promised on an early day. Possibly you may have later news direct from Peru. From Aberdeen I learn that Mr. Sinclair is expected before Christmas; but I do not know if the news of the illness was sent there.

THE CEYLON TEA CROP AND DELIVERIES OF CEYLON TEA IN LONDON.

We have already shown that the export of tea from Ceylon in 1891, will not exceed, if even it reaches 65 millions of pounds, and, of course the whole of this quantity will not reach the London market in the year. There is the quantity which will go into the imports of Britain in 1892 apart from the now considerable portion diverted to the Australian and other markets. But it may be interesting to compare deliveries with crop. In the 10 months ended October, then, the deliveries of Ceylon tea in London were 44,416,000 lb. Adding for the remaining two months of the year at the same rate we get a total of deliveries for all 1891 equal to 53,300,000 lb. or 11 to 12 millions less than our probable exports. Considering, as we have said that a very considerably less quantity than 65 millions, say 60 at the utmost will reach Britain in 1891, the figures would be satisfactory but for the evil name and the low prices which much of our tea has obtained. The comparative figures for deliveries for the 10 months in London, were:—

	lb.
Indian...	81,868,000
China ...	67,698,000
Ceylon...	44,416,000

In one, or at most two years, Ceylon will supersede China in the second place, and with good and wholesome and high quality tea we trust. All our efforts to obtain new markets will be in vain if strenuous efforts are not made to wipe away the disgrace which unprincipled (in some cases perhaps, thoughtless,) persons have brought on Ceylon tea.

TEA IN FOOCHOW.—We are assured by tea-men, well known to us, that they and all other holders of fine teas will keep them until next season. They probably exaggerate the real state of the case when they tell us that present prices would not do more than cover the cost of labour carriage, chests, lekin, &c., but there is no doubt their losses are extremely heavy. Some are still so comparatively well off that they will live through those bad times, but others will be ruined. Whether they will do better by carrying over these teas to the new season remains to be seen. From all we can learn it is exceedingly doubtful.—*Foochow Echo.*

NOTES FROM OUR LONDON LETTER.

INADEQUATE SAMPLING OF CEYLON TEAS—SUGGESTIONS WITH REGARD TO MINING LANE SALES—MR. ROGIVUE'S MISSION IN RUSSIA—CEYLON AND INDIAN TEA IN FRANCE—CEYLON TEA IN AMERICA AND MR. BLWOOD MAY—STANLEY WRIGHTSON TEA CHESTS—CEYLON ESTATES TEA COMPANY—LANKA COMPANY—A NEW COMPANY FOR BRITISH NORTH BORNEO.

LONDON, Nov. 20.

My last letter contained very full reference to the question at present under discussion with respect to the insufficiency of time allowed for the efficient testing of the samples of Ceylon teas. During last week the Tea Committee of the Ceylon Association considered this matter, but was unable to arrive at any decision as to the course to be taken, though it made several suggestions to be conveyed to the parties interesting themselves as to some remedial action being taken. The nature of these suggestions has already been conveyed to you by me, and the leading brokers have expressed the opinion that if they can be acted upon great relief will be obtained.

But the experience of last Tuesday's sales proves very conclusively that the real remedy rests to a very great extent with the brokers themselves, though these complain that they are not free agents in consequence of the pressure referred to in my previous letter put upon them by their constituents to press sales on. Now the sales of Ceylon tea of last Tuesday week included no less than 18,716 packages in 793 breaks. In each of the latter there was a sample. These were not, except in a few instances, available for tasting before the day preceding. It was a manifest impossibility for the intending purchasers to properly test these before the sales opened. Competent authority has expressed the view that the irregularity of the sales and the depressed prices obtained on that particular Tuesday were almost entirely due to this fact. On the Tuesday in this week there were less than half the number of breaks offering as compared with the week previous. The result to this was thus expressed in the market report of the day following the sale:—

"17th November 1891. Supplies were offered in a more manageable quantity of samples, there being less than half the number of breaks that were offered last week. Consequently the sales passed off with a very firm tone, and the irregularity noticed last week has to a large extent disappeared."

Manifestly it is the duty of the brokers to so arrange their sales that such an overcrowding of the market on any particular day should be avoided. It cannot be difficult, one would think, to average the supplies to be put forward. If your planters are to secure the proper result to their labour, they should take steps to place the brokers in a position to do this; and this can only be done by allowing to them a greater latitude in selection of a day for offering than is at present given to them.

The *Citizen* of the 14th November contained the following paragraph, certainly extracted from Messrs. Gow, Wilson & Stanton's tea circular. You will see it embodies the main point upon which I have previously written you:—

"The following will interest those in the tea trade:—The present rule of devoting Mondays and Wednesdays to auctioning Indian teas, Tuesdays to Ceylon teas, and Thursdays to both kinds, has now been in force more than three years. Since its institution the output from both countries has so vastly increased, that an alteration in the arrangement of public auctions is now

generally recognised as likely to be beneficial to both industries. Not only have Monday's auctions of Indian tea of late been occasionally very heavy, but last Tuesday's Ceylon sale of 18,716 packages comprised so large a number of breaks (793) that it was impossible for buyers to give careful attention to the entire sale—the result proving most unfortunate for importers. The obvious course to pursue, now that Ceylon has grown so enormously since the present plan was adopted, seems to me to devote more days to the sale of Ceylon tea. This would enable dealers to distribute their purchases over a longer time instead of operating practically only once a week, as they are now compelled to do, owing to the objection of Ceylon importers to sell late on Thursdays. To facilitate this operation, it may become necessary to hold auctions of Ceylon tea in a separate room from Indians, a result which might ultimately be advantageous to both industries, although perhaps at first attended with some slight inconvenience."

With reference to the final suggestion of the above extract, it has been mentioned to me that if Ceylon sales were to proceed simultaneously with Indian sales, and in a separate room, buyers would be placed in a considerable difficulty. They might want to purchase of both kinds, and it would be impossible for them, of course, to be in both rooms at once. Some, however, think that this difficulty would prove in practice to be more fancied than real. As to the provision of a second room, I have been told this week that it would be perfectly practicable, there being no sparseness of the accommodation required in the existing building. What course will be determined upon remains yet to be seen. Possibly, I should say, all the remedies I have suggested may be given a trial to, or even all of them, viz:—1st, greater discretionary power given to the brokers by your consignors; 2nd, the averaging of quantities to be offered on particular days; 3rdly, the conducting of the Ceylon sales in a separate room from that devoted to Indian, and simultaneous selling; and 4thly, an alteration in priority of offering at the Thursday's sales. Either one or other of these several courses must afford considerable relief, and it seems certain that the trade will not allow the present unworkable system to much longer continue.

My letters recently mentioned to you that Mr. Rogivue had experimented with a Ceylon tea kioska at the great Russian fair at Nijni-Novgorod. At the time of my writing, the source from which funds for this experiment had been derived was unknown to me; but from what has since reached me it would appear that Messrs. Spence, Willis & Co. undertook the whole financial responsibility of it. From what has before been written you upon this matter by me, you will have learned that Mr. Rogivue considered the result of that firm's enterprise to have been a successful one.

You will recollect that very recently, as the final result to rather disagreeable correspondence between the Ceylon Association in London and your Planters' Association, the latter approved of suggestions made by the first-mentioned body as regards the agency for the sale of your teas in France. In this connexion it will interest you to know what progress has been made by that agency which works the *Palais Indien* tea houses in Paris. At the statutory general meeting of his Company the Chairman gave very full details of what had been accomplished. He told his auditors that their work had been taken up in continuance of what had been done at the Paris Exhibition, and to prevent the fruits of their labour there from being lost tea-rooms had been fitted up in the Indian style in the most frequented parts of the city, at which pure Indian tea is sold in cup and in packets.

The first of these was opened about a twelve-month back, the second towards the end of April, and the third in the month of May of this year. The Company took over these establishments on its formation, and sufficient time had now elapsed to warrant an opinion being formed as to the prospects of success. From the moment of the establishment being opened they had secured a considerable measure of support. Each customer is supplied with a separate pot of tea, with milk and sugar, for half a franc (4^d). The service was decidedly superior to anything of the kind in England. Progress since the holiday season of the Parisian had been continuous. Every week and month showed, the chairman said, such satisfactory progress that it seemed probable that each of these places will be paying within three or four months. The third establishment was designedly opened away from the fashionable quarters of the city in the Boulevard Bourse Nouvelle in the neighborhood of some of the large theatres. Ceylon tea was kept in stock, but 90 per cent of their sales was of Indian tea. They had done well at an exhibition opened in the Champs Elysées in August, which remains open till the end of November and each succeeding month had increased the number of their customers. The Chairman continued:—"Our total sales in the year 1889 were over 16,000 francs, in 1890 over 30,000 francs, and in 1891 (estimating the two last months of the year on the basis of the others) they will be over 120,000 francs." No intention was at present formed to open further establishments in Paris, but the directors thought of trying branches in other parts of Europe and had secured a site at the Chicago Exhibition. Mr. Bullock (Chairman of the Upper Assam and Assam Frontier Companies) expressed an objection to any but Indian tea being sold. Mr. Seton said that the proportions of other teas sold was only one per cent of the total sale, and Mr. Thomas Lough remarked that "In the course of a few months Mr. Bullock's wishes would be carried into effect. There were several practical difficulties to deal with, but the board had taken steps to obtain the end desired."

It is to the closing utterance by Mr. Thomas Lough that it seems desirable to call the special attention of your Planters' Association, as I shall also take care that it has that of the Ceylon Association in London's Tea Committee, if it has not already been under that Committee's consideration. Mr. Lough was, as you know, appointed on his own application the recognized agent for Ceylon teas in Paris. Yet to judge from the words he is reported to have used, he would seem to be doing his best to exclude Ceylon tea from sale by the company he represents in Paris! I may, of course, be mistaken. You will notice that the Chairman stated that ten per cent of the teas sold were other than Indian. Did he use Indian as a generic term to include Ceylon; and did the ten per cent mean China or other teas used for blending purposes? If he did not include this, then Mr. Lough is apparently aiding him to keep Ceylon teas out of sight. It is to be hoped that we misunderstand this; but it is difficult to put any other construction upon what Mr. Lough is reported to have said. No doubt the *Palais Indien* Company is doing a good work in popularizing tea-drinking among the Parisians, and the taste for this established Ceylon teas are sure in time to find many patrons. But the question we are more particularly concerned with is how far, to judge from what he has said, Mr. Lough is fulfilling his compact as the recognised Agent for Ceylon teas in Paris? The matter certainly merits inquiry.

I have this week seen a letter from Mr. Elwood May to Mr. Leake in which he complains of the difficulties arising from want of adequate capital. He says that neither in England nor Ceylon have any of his Company's shares been taken up, and that it is very difficult to get the necessary cash capital from Americans. This does not surprise me, any more than it surprises me to learn that capital has not been subscribed either by people here or in Ceylon. We have perfect reliance on Mr. Elwood May and his good faith and intentions, but capitalists here are now very shy of investments outside of Great Britain or her colonies; and we fear Mr. May will have to depend entirely upon what capital he can raise locally. He tells Mr. Leake that "Our advertising contracts, for which we pay only in the stock of this Company, already amount to over 160,000 dollars."

Mr. Arkell, whom you will know to have been the gentleman who entered into the first of these contracts with Mr. May, has written to that gentleman:—"I expect from the present outlook to have the whole 300,000 dollars of your advertising placed within the next six months. To place this properly, it takes a long time, as I wish to get the very best results; therefore, it cannot be done in a hurry. From a close study of your enterprise I am fully convinced that a very large and profitable business can be made of it. I think your Company ought to expend, in addition to this 200,000 dollars in stock, 200,000 dollars in cash, and that certainly would put the Ceylon tea upon the market under all hazards. If your Company, or members of it, would raise 175,000 dollars in cash to be used in this direction, I would be willing to 'chip in' 25,000 dollars and take it in stock at par, with understanding that no stock is to be sold less than par."

Evidently Mr. May wants cash to work his enterprise, but it is much to be feared he will not obtain it on this side of the Atlantic. The question is if he was not too sanguine of the support to be obtained in England and Ceylon. He would seem to have forgotten the many other quarters in which you are making efforts to introduce your teas, and that nearly all the capital which might otherwise have flowed in his direction has been absorbed by such ventures.

Mr. May has been obtaining the opinion of certain strawboard manufacturers in America as to the cost of making the Stanley-Wrightson tea chests by them, and we are surprised at hearing from him that their price quoted is 1 dollar 50 cents, equivalent to about 6 shillings per chest. Making every allowance for the higher cost of labour in America, it is impossible to see how such an estimate can be justified, for the boxes were made here at a cost of 2 shillings each! If the price quoted cannot be reduced, it is not likely that the States will furnish an opening for the Stanley-Wrightson boxes.

The Ceylon Estates Tea Company has opened a very neat-looking establishment at 166, Fenchurch Street, the agents working it being Messrs. Edwards & Co. Fenchurch Street is, of course, an admirable locality for such an establishment, and we have no doubt the Company will find its full account in it.

The Lanka Company has removed from its former office in the Old Jewry and has taken fresh ones at No. 12, Fenchurch Street. The report of this Company should now be in course of preparation, and no doubt is, but it was too late when I called at the old address this week to return to make inquiry at the changed one.

Borneo seems still to attract investors, though we have not yet heard of very successful results

to any enterprise connected with it. The following extract refers to a new venture of the kind:—
 The British North Borneo Development Corporation (Limited) is a new company, with a capital of £300,000, divided into 299,500 Ordinary shares of £1 each and 500 Founders' shares of £1 each. The present is an issue of 200,000 Ordinary shares and 350 Founders' shares, of which 29,650 Ordinary shares and 350 Founders' share will be issued as fully paid to the vendor in part payment of the purchase-money, and the balance of 170,350 Ordinary shares are now offered for subscription. The company has been formed for the purpose of acquiring and developing several concessions of lands and other advantages in British North Borneo, at and near Saadakan, capital of that country.
 —London Cor.

THE JAFFNA TOBACCO TRADE AND THE GOVERNMENT OF TRAVANCORE

We quote the following from the *Hindu Organ*:—
 We referred at some length, in our issue of the 28th ultimo, to the wretched plight into which the Jaffna tobacco trade with Travancore has been reduced by the Government of that State, reducing the duty on Coimbatore tobacco without at the same time reducing the duty on Jaffna tobacco also. Not content with the injury thus caused to the Jaffna tobacco, that Government, according to recent intelligence received here, is now enforcing without any previous notice or warning, another new order, equally prejudicial to the interests of the Jaffna tobacco. It has been the practice hitherto to store the tobacco imported into Travancore in the several Government bankshalls and to weigh it for duty when it is sold and removed away from them. The native Government now insist that the tobacco should be weighed immediately after landing in the customs, and that the duty should be paid according to this weight, and not as heretofore according to the weight at the time of its removal from the bankshalls. The Jaffna tobacco is prepared here to suit the Travancore market, moistened with tea water, and it will not become dry and fit for consumption till after some months of its landing there. In the meantime, every bale will be reduced several pounds in weight. The merchants are, therefore, against custom and long continued practice, now forced to pay duty for weight which does not actually exist at the time of its removal from the Government bankshalls. Judging from these proceedings, it seems that the Government of Travancore are determined to favour the Coimbatore tobacco at the expense of the Jaffna product. The merchants who suffer these wrongs at the hands of that Government are British subjects, who have been enticed by the just and equal laws that had prevailed there to invest their all in that trade, but who now find themselves in a helpless condition, these laws being suddenly altered to compass their ruin. We feel sure that if the whole case were properly laid before the Colonial Government, a strong representation will be sent by them to the Government of India protesting against these questionable proceedings of the native State.

SOME ACCOUNT OF THE NUTMEG AND ITS CULTIVATION.

By THOMAS OXLEY, Esq., A. B.,
Senior Surgeon of the Settlement of Prince of Wales' Island, Singapore and Malacca.
 (From the "Journal of the Indian Archipelago and Eastern Asia.")

(Continued from page 464.)
 But although unarriving is the chief element in successful cultivation, there are many other matters for the planter to attend to during the period that his trees are growing. All bad grasses must be carefully kept out of the plantation, at least from between the trees, and the harmless grasses rather encouraged as they keep the surface cool. I have seen the reflected rays of the sun from an uncovered whitish soil, regularly scorch up the leaves although

the plant was covered over on two sides and the top by the usual artificial shade. The trunk of the tree ought to be carefully washed with soap and water once a year to keep it clear of moss, this has been ridiculed as being a work of supererogation;—let those who think so, omit the operation. Parasitical plants of the genus *Loranthus* are very apt to attach themselves to the branches, and if not removed do great injury, in fact if altogether unattended to, they will in time destroy the tree. The enemies of the Nutmeg tree are fortunately not numerous, but they have a few; white ants among the number. I know of no remedy for these but cleanly and good cultivation, they seldom if ever attack a vigorous plant; it is upon the first symptoms of decay that they commence their depredations,—their nests may surround a tree and their small tunnels pierce the earth in every direction about its roots without the plant giving any indications of decay, but whenever I have discovered them in such localities I have always endeavoured and often successfully, to dislodge them by a dose of a solution of pig dung, an article apparently not at all to their taste, although fresh cow dung is a strong source of attraction, another reason to those I have already given for using this latter substance in a perfectly decomposed state when it can be well mixed up with the soil, and appears no longer to have an attraction for those destructive insects, which cannot be too jealously watched, for when once they attack a tree the case is hopeless. The first notice a planter has is the withering of the leaves, and when he comes to examine he generally finds it necessary to dig up and uproot the plant at once, rather than leave it as a nidus for those voracious depredators; every planter must lay his account to losing occasional trees by them, but he who has his ground cleared and most free of old roots and stumps of trees will lose fewest. There are several species of insects which lay their eggs on the leaves but they are not all of equal importance; that which manifests itself by the discolorization of the leaf, and the larvae of which are embedded in the substance and rot on the surface, appears the worst, but all ought to be carefully watched and removed or they rapidly spread and cause great havoc amongst the trees. For this purpose it is necessary to wash the leaves with a decoction of Tuba root, and syringe them by means of a bamboo with Chunam and water of the consistence of white wash, this adheres to the leaves and will remain even after several heavy showers giving for the time rather an unsightly appearance to the tree, but making amends by clearing it of the larvae already alluded to; another nuisance is the nest of the large red ant; these collect and glue the leaves together forming a cavity for the deposition of their larvae. All leaves thus made use of turn yellow and die; they do not that I have observed otherwise injure the tree, but trees so infested do not bear well and the ants bite the collectors severely, and indeed any person incautious enough to brush against the tree. The best mode of destroying them is to hang a portion of some animal substance such as the entrails of a fowl or the like to the end of a pole, the opposite extremity of which is allowed to pass through the branches, the ants will run along the pole and collect in immense quantities around the bait, when by a lighted faggot they can be burned by thousands. This operation repeated a couple of times a day for a week or so, will rid the tree of the invaders, their nests should be broken up by the collectors as they go their rounds, but this they are very unwilling to do seeing that there are few insects more ready to revenge themselves, and the coolies never fail of a good biting whenever they try the experiment of disturbing them. I have now made the planter tolerably well aware of what he has to do and of most of the difficulties he has to encounter. I shall now endeavour to give some notion of the prices of labour and material, and speak of the work best done by contract and that which one had better perform with the labourers on the estate.
 The first operations of clearing ground and digging the holes can be done more cheaply by contract labor than by men on monthly hire, very little

supervision in such case being required as it is easy to see whether the ground be well cleared or not, and the size of holes being determined previously, there can be no dispute about the matter afterwards. It is surprising how much better the Chinese work when they are paid by the task rather than the day, and singular enough they are better content, working harder and earning less by the former system than the latter. Few labourers in the world can equal them when working on their own account, but on regular wages they are most complete eye servants: they are however upon the whole the best class of field labourers. The usual monthly pay to good strong men is 3 to 3½ Spanish dollars per month, but those who have become expert at any particular work very soon discover their value and cannot be kept without an increase of wages. Malays are to be had for dollars 2½ per month, and it is well to mix them with the Chinese; in making sheds for trees and all work where the rattan is used, they are more expert, they are also more to be trusted, and are a very wholesome check upon the vagabond sons of Han. Patience and temper are eminently necessary to get on with the Malay; they are not to be driven, but kindness and a little banter occasionally have excellent effect upon them. The Boyans are the most quiet, the most honest, and the most to be trusted of any of the races we see here; they are very slow and not over bright, but they perform their work as well in the absence of the overseer as before him, and they are by far the best nut gatherers. The Klings, or natives from the east of Coromandel, are good workers if they choose to exert themselves, but they are the most wretched eye servants, and seem to delight in chicanery of all sorts: unlike the Malay, fear is the only motive capable of exciting them to action, and the application of the Mandor's or Superintendent's rattan seems the only argument they understand; they are chiefly valuable in taking care of horses or cattle, cutting grass and driving carts; all other work is better done by Chinese or Malay; their wages is about the same as Chinese labourers, that is from 3 to 3½ dollars per month.

Manuring, making sheds over young plants, and extirpating bad grasses, are works which had better be performed by the regular monthly labourers on the estate, and indeed so soon as a plantation comes into bearing all contract labour must cease, as by admitting strangers the facilities for robbery would be more than any supervision could frustrate. The number of men to be kept on an estate, to preserve it in first rate order, after it has come into bearing, must depend of course upon the size of the plantation, but in general one man for every 100 trees will be found sufficient, provided there be some 4 to 5 thousand trees. On a small scale the proportion must be greater, as the idlers, such as those who take care of and repair the spics, gather the nuts, and manage the horses and carts, tell more upon a small than a large scale. A man by planting the Guinea grass and feeding cattle may make his own manure, and I believe it to be the best mode of proceeding; those who depend upon the town for their supplies will frequently meet with disappointment and never obtain such good manure. The price of manure generally speaking is about 8 cart loads for the dollar, each cart containing 20 baskets. I conceive that two such carts with a similar amount of burned earth to be little enough manure for a tree of 12 years of age. It is almost impossible for a Planter to manure the whole of his trees in the same season, if they amount to several thousands: in this case the best plan is to divide the property into sections, manuring them in regular rotation, and to apply a few baskets of manure as top dressing to any particular trees that show symptoms of flagging.

The nutmeg Planter is under the necessity of keeping up nurseries throughout the whole of his operations, for the replacement of bad plants and redundant males. Of the latter, ten per cent seems to be about the best proportion to keep, but I would have completely discarding trees. No person can boast to get a plantation completely filled up and in perfect order much sooner than 15 years. Of the first batch planted

not more than one half will turn out perfect females, for I do not take into account Mombosious trees which I have already condemned. The tree shows flower about the 7th year, but the looger it is before doing so, the better and stronger will it be. I cannot refrain from a smile when a sauguine planter informs me with exultation that he has obtained a nut from a tree only 3 or 4 years planted out,—so much the worse for his chance of success, too great precocity being incompatible with strength and longevity. The best trees do not show flower before the 9th year, and one such is worth a score of the others. This will be evident when it is stated that I have seen several trees yield more than ten thousand nuts each in one year, whereas I do not believe that there is a plantation in the Straits that averages 1000 from every tree. This very great disparity of bearing shows plainly that the cultivation of the plant is not yet thoroughly understood, or greater uniformity would prevail, and I think it clearly enough points out that a higher degree of cultivation would meet its reward. It is not quite safe to cut down the male plants upon first showing flower, as they many times show perfectly female flowers the following year, and in that case are generally the strongest and finest trees. But there is some indication of this in the first mode of flowering. When the racemes are many times divided and have numerous flowers, there is no chance of its becoming entirely female, but where there are only two or three flowers on a raceme there is a fair prospect of its doing so. The tree has not been introduced into the Straits sufficiently long to determine its longevity, but those introduced and planted in the beginning of the present century as yet show no symptoms of decay. The experiment of grafting the trees, which at first view presents so many advantages, both in securing the finest quality of nut and the certainty of the sex, has still to be tried in this cultivation. Some three years ago, I succeeded in grafting several plants by approach, those are not sufficiently old for me to decide whether it be desirable or not, for although the plants are looking well and growing, they as yet have thrown out their branches in a straggling irregular manner, having no leaders, and consequently they cannot throw their branches in the regular verticles necessary for the perfect formation of the tree, without which they must ever be small and stunted, and consequently incapable of yielding any quantity of produce. The grafts have succeeded so far as stock and scion becoming one, and in time a perpendicular shoot from the wood may appear. If after this it should increase in size and strength so as to form a tree of full dimensions the advantage gained would be worth any trouble, the quality of some nuts being so far above that of others it would make a difference beyond present calculation; in short 1000 such planted trees at the present prices would yield something equivalent to twenty thousand dollars per annum, for \$20 per tree would be a low estimate for such plants. If this ever does occur it will oblige the aspect of the cultivation altogether, and I see no good reason why it should not, except that those possessing trees of the quality alluded to, would not very willingly permit others to graft from them, so it is only the already successful planter who can try the experiment properly.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Nov. 21st.

CINCHONA.—The periodical actions of cinchona bark were barely up to the average as regards quantity offered. The total supply in the catalogues consisted of

	Packages.	Packages.
Ceylon...	999 of which	972 were so d
East Indian ...	463 "	379 "
Java ...	102 "	87 "
South America ...	193 "	110 "
	1,754	1,518

The bark offered contained a more than average portion of Officialis parcels from India and Ceylon, and also included a supply of about 113 packages of Darjeeling bark, a variety which has not been offered in public

sale for several years. The offerings of South American barks were small, and in no way remarkable. Competition throughout the sale was fairly active, nearly all manufacturers participating in it. Prices showed no notable change, but there was, perhaps, some slight tendency towards greater firmness. The unit remarks at 1 1-16ths d. to 1/4 per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amstordam works...	120,543
Messrs. Howards & Sons ...	89,825
Agents for the Italian and American works ...	56,742
" Auerbach factory ...	31,248
" Frankfort o/M and Stnttg ...	27,461
" Bronswick works ...	23,985
" French works ...	8,850
Mr. Thomas Whiffen ...	1,431
Sundry druggists.. ...	25,829
Total quantity of bark sold ...	368,235
Bought in or withdrawn... ..	85,872
Total quantity of bark offered the ...	404,107

It should be well understood that the mere weight of bark purchased offers no guide whatever to the quinine yield represented by it; firms who buy a small quantity of bark by weight frequently take the richest lots, and vice versa.

CINCHONA.—A parcel of 4 bales of Huacoco bark, the first of this variety which has been imported this year has just arrived; the last price paid for this class of bark was 1s 3d per lb., but in view of the great scarcity the importers expect to get a trifle more now. The following are the approximate quantities of bark, with their equivalents in sulphate of quinine added in (), purchased by the various competitors at the last Amsterdam auctions:—Auerbach 100,570 kilos (4,240 ko.); Philadelphia 66,929 kilos (2,775 ko.); Mannheim and Amstordam 43,228 kilos (2,052 ko.); Brunswick 33,234 kilos (1,879 ko.); Paris 19,789 kilos (900 ko.); Howard & Sons 19,378 kilos (1,080 ko.); Frankfort and Stuttgart 12,925 kilos (640 ko.); Hoppert & Heyse, Amstardam 5,177 kilos (228 ko.); druggists 16,700 kilos.

CINNAMON.—The market has advanced further, and sales of 200 bales Ceylon, second quality, have been made this week at 7 7-16ths d. to 7/4d per lb. At auction yesterday 250 bags chips were partly sold at 2 1/2 per lb.

QUININE.—Very flat; a sale of 5,000 oz at 9/4d second-hand was reported, yesterday, but has not since been confirmed. The B & S agents sold a small quantity this afternoon at 9/4d per oz. The following are the present quotations of the manufacturers:—Howard & Sons 1s 1d to 1s 2d in tins, 1s 3d to 1s 4d in 1 oz vials; Thomas Whiffen 1s 1d in tins, 1s 3d in 1 oz vials; Zimmer and Jobst 1s in tins; Milan 1 1/4d in tins, 1s 1/4d in 1 oz vials; Pelletier's 1s 9d in 1 oz vials; Auerbach, Brunswick, Mannheim 10d per oz in tins.

THE LANKA PLANTATIONS COMPANY, LIMITED.

Report to be presented at the Eleventh Ordinary General Meeting of the Lanka Plantations Company, Limited, to be held at the Offices of the Company, on Wednesday, the 2nd December, 1891, at 3 o'clock in the afternoon.

1. The Directors submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date.

2. The coffee crop was 2,031 cwt., and the amount realised therefrom was £9,603 18s 9d. All fields of good coffee are receiving liberal cultivation, but each year the acreage becomes unavoidably smaller. The Thotulagalla estate continues to give satisfactory returns, as well as some fields on Ampittiake, Arnhall, Rappahannock and Gonagalla.

3. The cinchona bark shipped has been 61,905 lb., which has been realised, and produced £731 12s 10 1/2. There is no improvement in this market, and the only outlay made on this product is that of harvesting Bark from trees which are oakened, or which injuriously affect the Tea or coffee beneath them.

4. Cocoa realised £5,071 10s 6d, the quantity gathered from the 311 acres now in bearing being 1,106 cwt., shewing a profit thereon on the 12 months' working of £2,856. The following extract is taken from the Superintendent's Report dated 15th July:—

"Last year I planted 18 acres of cardamom with cocoa, the growth is remarkably good even for Yatta-

watta. I have noticed also along the jungle boundaries, and through the jungle, that cocoa plants from seeds carried by monkeys are springing up wild and competing with the natural growth, which shows that the plant has thoroughly established itself in this locality."

The cocoa trees are very favourably reported on and there is every prospect of a good crop again this season.

As the acreage in Ceylon suitable for the successful cultivation of cocoa is limited, the Directors confidently look forward to present quotations being maintained for this product.

It seems therefore most desirable that a very considerable extension of acreage under cultivation should at once be made, but the Directors cannot undertake this expenditure out of income, and unless the Shareholders will take up a substantial amount of the unissued 6 per cent. Cumulative Preference Stock it cannot be carried out. The cost of planting and cultivating Cocoa, until the plants begin to bear enough crop to pay expenses, is about £12 per acre, or £2,400 for 200 acres; a moderate subscription from each Shareholder would produce this sum. The calls could be spread over the year, and the interest would be but a slight burden on the net profits. The Directors therefore enclose a form of application for Preference stock and will open as much land as the subscriptions justify.

5. The cardamoms have produced 3,224 lb. The amount realised therefrom was £271 1s 4d.

6. The tea received from the Company's estates, without purchase of any outside leaf, has amounted to 248,574 lb., which have realised £9,627 11s 2d, an average of 9 1/4d per lb. nett. The leaf from Rappahannock and Rillamulle is manufactured in adjacent factories, the rest in the Company's own factories. A small amount of leaf is being plucked on Thotulagalla, and this for the present will be sold to a neighbouring estate.

The following Statement shows the acreage and state of cultivation of the Company's estates on the 30th June last:—

Estate.	Coffee.	Cin- cna.	Tea.	Cocoa.	Carda- moms, &c.
Ampittiake	100	...	193
Arnhall	132	40	124
Fruit Hill	220
Fordyce Garbawn, Gonagalla and Paramatta	235	...	527
Rappahannock	40	21	270
Rillamulle	28	...	187	...	15
Thotulagalla	220	...	145*
Yattawatte	384	41
	755	61	1,666	884	56

* Partly in Coffee.

	Grass.	Pattina.	Forest & Timber	Total.
Ampittiake	2	3	34	39
Arnhall	15	37	25	77
Fruit Hill	25	25
Fordyce, Garbawn, Gonagalla and Paramatta	23	16	185	224
Rappahannock	25	62 1/2	55	142 1/2
Rillamulle	2	6	20	28
Thotulagalla	...	143	50	193
Yattawatte	95	150	277	522
	162	417 1/2	596	1,175 1/2

The profits for the past year amounted to £6,443 2s 6d, and had the rate of exchange during the first half of the year not ruled higher than it has done during the last few months, the profits would have been much better; as it is, they are sufficient for the dividend on the Preference Shares and also to pay nearly 4 per cent on the Ordinary Shares, but deeming it expedient, having regard to possible depreciation, to reduce the Machinery Account by £410 Os. 10d., and having to reduce the Suspense Account by £1,427

0s. 6d., the Directors have taken £1,837 1s. 4d. from the profits for these purposes, and they now recommend the payment of the dividend of 6 per cent. on the Preference Shares, and a dividend of 5/- per Share (free of Income Tax) on the Ordinary Shares, carrying forward a balance of £727 19s. to the next account.

Sir R. P. Harding and Mr. Edward Pottit retire on this occasion, and being eligible offer themselves for re-election.

Mr. John Smith, the Auditor (a Shareholder), also retires and offers himself for re-election.

The Directors regret exceedingly that they have had to accept the resignation, from failing health, of Mr. Wm. Bois, who since the formation of the Company filled the post of Secretary to their entire satisfaction, and who still remains a Shareholder.

A Summary with the details and the Report of the Agents may be seen at the office.

By Order, C. M. ROBERTSON, Secretary.
12, Fenchurch Street, E. C. Nov. 1891.

These papers have now been continued over the month when the north-east monsoon should have proved itself, and yet we see that even in November there was a north-east wind only on the 6th of the month, and the only other day on which the wind was east was on the 28th, when it was E. S. E., and for not less than 15 days out of the 30 there was a west wind, and only for 9 out of that 15 partaking of a direction partly north. The maximum thermometer on the 11th when it was 85° drew on a heavy fall of rain, over four inches, only to remind us of the heavy fall in October, and to ensure that the rest of the month would be comparatively dry. There was evidently nothing connected with the changes of the moon or harmonic changes deserving of special mention. The sensation of heat continued throughout, and continued to be normally unaffected by the fall of rain. The nights were perhaps cooler in other parts of the island; but in Galle it is only when near December that there is any promise of improvement in this respect. And so, we close our little observatory for the present.

T.

A TALK ON TOWER HILL.

THE other day that famous physician Sir Andrew Clark gave a prescription for a really nice cup o' tea, which appeared in these pages. This has excited so much interest in the bosoms of so many correspondents that we sent one of our representatives to have an afternoon tea talk with another famous Tea Doctor—namely, Dr. "Mazawattee," whose consulting-room is on Tower-hill. The following is a short account of our representative's visit:—

The Mazawattee tea warehouse is an immense brick pile that stands on Tower-hill. There were so many doors in the building, so many windows, so many pairs of stairs, so many chests of tea, that they would have furnished a mathematician with examples for a new arithmetic, especially if he possessed the gift of a Hamblin Smith for such matters. After fighting our way between the horses and vans—there was a big crowd despatching and receiving—we made our way to the lift and rattled up to the top of building. In a few seconds we were in the printing-room in the centre of a busy crowd; men and boys turning out labels for the packets of tea, stamping diaries—a neat little book of 144 pp. printed by constable of Edinburgh—with the names of clients; binding up an abridged English dictionary, and "A Language of Flowers," both of which have been distributed in millions by the firm as a *vade mecum* to their wares; sorting out Mazawattee envelopes with the firm's patent "loving cup" opener; or rattling off at the printing-presses' bit-heads and account-books for the customers. In another room the whirl of the steam saw might be heard, and the hammers of the joiners making old packing-cases into new ones. On the next floor we came across the secret of the success of the Mazawattee tea. It was a section of the blending department. In one instance nineteen and in another fifteen chests of different sorts of tea stood ready to be poured into the mixers to get the standard quality for one or other particular blend; for the principle is that, once having discovered an acceptable blend, it is registered. The taster consults past records, spreading over from that of the last mix to that compiled often six months ago, and aims always at producing a tea similar in taste and quality to that which has been acquired before. This, of course, can only be accomplished in very large establishments, and it is this order of things and the sealed packet system, such as that of the Mazawattee tea people, which ensures the customer receiving a uniform article time after time. The rows of mixers looked monstrous. Each holds a ton of tea. We wondered how all the tea was consumed. The wonder was removed when Mr. Lloyd, who was kindly showing us over the building, pointed out that the firm have agents in every village, town and city from Land's End to the Shetlands, from Cape Clear to Rathlin, and that the yearly output by the firm exceeded 12,000,000 packets of tea. We took a peep inside the mixers. They are lined with a series of shelves; the tea is shuffled off from one shelf to the other and so ensures a perfect blending. In this room there stood other machines for breaking up the large loaf, from which, in its original state, it is practically impossible to obtain a perfect brew, but when broken up in this way the big leaf makes an excellent beverage. Another and yet another flight down; both rooms were filled with a crowd busy at work. Here the tea was being run from the accumulators; a hundred hands were weighing it, and doing it up in the now familiar twofold packets with their labels of yellow, dark red, black, brown, and green, with gold letterings, and storing the pound and half-pound packets in trays of 10 lb. divisions, ready for the packer. Tea bloom in these rooms appeared to permeate everywhere. The men and boys looked as if they had been in a shower of gold, and the aromatic odour from the bloom made one feel full of delight. Somewhere November, on the morning of our visit, seemed to have taken a leaf out of spring's book. The sun was shining brightly on London's most ancient pile, the Tower, as we wended our way out to Messrs. Densham's tasting-

rooms in Philpot-lane, through the tiers and piles of cases waiting for despatch by the numerous carriers to their respective destinations. For, though "Mazawattee" is comparatively a new definition, the firm of Densham and Sons is an old one, and one of wide experience, and this is all in all to the consumer. As we tramped along Great Tower-street we gathered from Mr. Lloyd that it may be taken as an invariable rule that, although cheap teas are good, the higher priced ones are better. "Sir Andrew Clark tells his patient to get a 'good cup of tea,' does he? Now, of course, all our teas are good, and cheap teas are equally carefully selected, but you can't expect the same same fine quality at one shilling and tenpence per pound that you get in our Golden Tips!" In the tasting-room there stood piles of small, flat round tin boxes, filled with samples from the chests, under consideration for the blenders, and rows of little white tea-gauges with lids and basins lined other counters. A boy, kettle in hand, was making the round of other tastegroups into which samples had already been turned, pouring piping-hot water into them, and setting the saucer-glass in order to know how long to keep the brew going. As we sniffed this pot of tea and wetted our lips with that one we were compelled to confess to being novices. Neither did we envy the taster his profession—certainly not when we learnt that an ordinary daily task with him was to make some six hundred tastings.—*Pall Mall Budget*, Nov. 26.

THE COFFEE DRINKER'S LAMENT.

Mr. John Hughes writes:—Analytical Laboratory, 79, Mark Lane, London, E. C. Nov. 20th.—A correspondent in the *Daily Telegraph* having written a long letter lamenting that no good coffee was obtainable in this country the following replies were the consequence.

Various correspondents write to express their views upon this subject. Mr. George Newton disputes the assertion of "Purple Drup" that the finer growths of coffee rarely reach England, and only in small quantities imported to special order. He says, "I am acquainted with one firm in this city—whose address I enclose for your satisfaction—who import and sell on this market from 500 to 700 cwt. of Mocha coffee annually, and although they are the largest importers of the article, there are other firms doing similar business. Moreover, it must not be forgotten that we import largely of other coffees—Brazilian, Java, Mysore—a good proportion of the finest quality, and by some preferred to Mocha. Beyond all controversy there are numerous retail shops, both in and out of the City, where the pure article can be bought, but either the prolonged habit of swallowing the nauseous compound which prevails here has destroyed the appreciation for that which is good, or the public will not give the price necessary to secure berries of fine quality. Hence the abomination you are expected to swallow in nine cases out of ten, both in public and private life." With regard to the proper way of making coffee for the table, he remarks: "Years ago—thirty or forty—and, for all I know, now, it was the custom to boil (and perforce to spoil) coffee; and although this generation is conspicuous for the number and variety of contrivances specially designed for making it, the outcome of all inventive effort is a variety of machines of greater or less complexity for the performance of an operation of the simplest nature conceivable. I am a great lover of coffee, and I believe, somewhat of a connoisseur, and during my whole life have never used anything but an ordinary covered hot water jug for its manufacture. One of your correspondents asks for a recipe for making this delicious beverage. Here it is for any who care to use it. Heat the aforesaid jug by pouring into it and out again boiling water, put therein coffee in the proportion of three piled teaspoonfuls for half a pint of the beverage, and pour on it sufficient boiling water, five minutes later pour a little into a teacup and return it to the jug twice, and then let it stand in a warm place for 15 minutes. Result, a

cup fit for the gods. Much insistence is made by some that the coffee be freshly roasted and ground. My experience is that the value of both operations is much exaggerated. I roast and grind my coffee—pure Mocha—and if it is kept in a closed vessel of metal, earthenware, or glass, no discoverable deterioration takes place by keeping."

Mr. John Hoock, of 29, Bishopsgate-street Without, as one "who knows what is going on in the great coffee markets of the world," also controverts the statement that pure Mocha never reaches England, and quotes Professor Palgrave's report in the "Encyclopædia Britannica" to the contrary. "With regard," he adds, "to the other choice coffees which your correspondent boldly asserts never reach London, I may tell him that in the opinion of men who spend their lives tasting coffee and comparing values, Java and Martinique never have produced coffee that would in any way approach the splendid flavor of Vera Paz, which until recently has been sold under the name of Honduras, and which is considered by experts to be the finest coffee ground."

"Amateur" writes to give modes of making both tea and coffee. He says: "For tea, use freshly boiling water, infusing the leaves for not less than three or more than four and a half minutes, removing the leaves, and using the liquor, with new milk to taste. The use of condensed milk, I think, improves coffee or cocoa, but spoils tea. For coffee, I use not less than two ounces, to one pint of cold water, or one pound to one gallon, stirring it into, and allowing to stand not less than twenty-four hours, in an earthenware vessel. I object to metal utensils for coffee, and also boiling the liquor; so when the coffee is required I stand my earthen, or china, pot in a vessel of boiling water until the temperature of the coffee reaches, say, 210 deg., or just short of boiling point, and it is ready for use to flavour my hot milk to taste."

Mr. W. Maxwell Maynard, writing from Broomrigg, Dumfriesshire, desires to "try and relieve the sufferings of 'Victim,' whose pathetic cry found expression in your columns." As to kinds of coffee, he believes Mysore plantation is as good as anything ordinarily to be procured in the markets, and proceeds to give a recipe for making it. "Supposing a pint of good coffee is required for breakfast, grind some coffee the night before, take an earthenware jug of suitable size, warm it and put three ounces of the ground coffee into it and pour upon it one pint of boiling water. Stir it well with a spoon, cover it with a clean damp cloth, folded five or six times, to keep in the aroma, and stand it at the cool side of the kitchen range. Give it a good stirring three or four times in the course of the evening, then remove the spoon, replace the cloth, and put it anywhere where it will not be disturbed till next morning. Before breakfast gently raise the jug and pour off the liquid through a bit of thick wet flannel (well washed), and this will catch any floating grains. Put the clear liquid into a china-lined saucepan, warm it, and serve in a jug. In pouring out coffee the rule is, half coffee and half boiled milk and a little cream. Also avoid putting the coffee into a metal pot—it is infinitely bitter if it never touches metal at all. Never use less than three ounces of coffee to every pint of boiling water."

THE WILD FLOWERS OF FLORIDA.

I will endeavor to give your readers a description of our wild flowers, shrubs, etc. Florida is called "the land of flowers," and I think she justly deserves the title. If we were to gather up the wild plants in our woods, what a beautiful flower garden we might have. Many of our native plants have been introduced and bring good prices, while many have been passed unnoticed. In early spring, January, and February, we have Violets, three distinct varieties,—the Pine-woods Violet, which is supple and slender in habit with large flowers varying from white and palest blue to deep blue and reddish violet; the Hammock Violet, which grows close to the ground, firm and compact in habit, with deep blue

violets on short firm stems, the leaves are similar to the English Violet. Then there is the White Violet which grows in low lands and swamps, has a mass of long narrow leaves and any quantity of small white violets. They are beautifully marked, and I have often thought how much handsomer they would be for Bouttonieros than the blue ones—the flowers are the same size as the English Violet—sometimes larger. They are slightly fragrant.

The Yellow Jessamine (*Gelsemium Sempervirens*) with its deliciously fragrant bell-shaped flowers and lovely foliage makes attractive many an unsightly stump and neglected cottage, and decks the woods with its glory. The wild honeysuckle (*Azalea Nudiflora*) is a shrub found growing on edges of creeks and branches. The flowers are borne in clusters, very fragrant and in all shades of pink and light red. The pistils of the flowers are very long—hence the name—Wild Honeysuckle. This is a valuable plant for bees. The White Elder makes a tree here, and is also found near water. The flowers are valuable for bouquets, etc., and the berries make fine jellies, jam and pies. The jelly is very beneficial when used as cough medicine. The flowers make a tea excellent in cases of dropsy, and it is useful in many ways, in fact everyone ought to plant an Elder in their yard. We have any quantity of the Prickly Pear Cactus which has large brilliant yellow flowers in the spring, and is followed by small fruit a pear, which becomes a deep red when ripe, and is fine for jelly and pickles. The Prickly Pear has medicinal qualities, but I am not "posted." The Dog Banana (*Asimina Grandiflora*) is a low growing shrub with large straw colored and deep maroon flowers, followed by clusters of small bananas which are said to be edible. The Easter Lily (*Zephyranthes Tretea*) a pure white delicately scented lily, springs up singly out of the ground in low places. It is much used in floral decorations. A species of clematis with beautiful foliage and delicate flowers renders the low swampy lands very attractive in spring. We have a large variety of ferns, mosses, etc., fine for aquariums, also a species of the Resurrection fern. Then there is the Milkweed with its long pods containing silky floss. I hear it is a rubber plant. The Magnolia blooms in April and May. We have the Swamp and Highland. The Swamp Magnolia has the handsomest foliage. The Sweet Bay makes a large tree, the flowers are about the size of the top of a small teacup. The Bay does not bear seed, but the Magnolia produces an abundance.

During the summer and fall we have an endless variety of flowers—Lillian Luteum a double yellow pond lily—fills our creeks. They are showy but have an obnoxious odor. We have the double white Pond Lily in swamps and lakes, also in little arms of the river. The white "Crimum" or Spider Lily is very sweet and thrives in the creek edges. The Veiled Lily (*Paneratium*) is found in Southern Florida. The purple Iris (Flour du Luce) grows along the creeks and swamps. It is a showy flower. The Scarlet Hibiscus waves its flaming banner in the grey marsh grass, and two species of Althea with handsome silvery leaves flourish there also. One has a medium sized deep rose flower, the other a very large light pink with maroon centre and pistil like the Calla. Bullrushes and a species of Agapanthus are also at home here. We have a miniature snow-ball, cream colored and fragrant, which grows along the creek. Two species of Begonia, one with coarse leaves and dull red trumpet shaped flowers and the other with handsome foliage and brilliant red flowers. The Virginia Creeper (*Ampelopsis Quinquefolia*) grows luxuriantly here. We have one lovely species of Passion flower (*Passiflora Incarnata*). In the low land is found the Wild Tiger Lily (*Lilium Catesbaei*). It is deep orange red with dark spots. Golden rod grows to perfection here, and I must not forget the purple Thistle, which furnishes us with silky white pompons for our hats. In the swamps there is the Tulip tree and wild Laurel, the latter is good for flavoring meats and sauces. *Sassafras* grows wild here. "Life everlasting" is a small plant gathered (the roots) by the colored people and sold

at the drug stores. They also skin our prickly Ash for the same purpose. It seems a pity! We have a Sumac, too, and numerous other vines and flowers which I will not mention for this grows already too long. The "Yucca"—commonly called Spanish Bayonet—is a grand old shrub. It sends up a head, or spiko rather, from which hang suspended dozens of pure white waxy bells.

I feel that I have only told you half, but space forbids. This neighborhood before the war was an indigo plantation, and many bushes still remain as an emblem of past and gone grandeur. I read the letters of our sisters with great interest and hope you will all come forward and tell us of the flora of your State.—"Aida," in *Homo Journal*.—*Florida Agriculturist*.

THE INDIARUBBER INDUSTRY OF DUTCH GUIANA.

The caoutchouc, or indiarubber, is produced in Dutch Guiana under different species, the most important of which is "balata" or "milk of the bullet tree," the export of which, says Consul Wyndham, of Paramaribo, is attaining considerable proportions, and will, it is believed, be very productive for a time only, as there is no forest conservancy law in the colony. Persons who are granted tracts of land for the gathering of this product are uncontrolled in their method of drawing the milk, which results in trees being totally destroyed to get the greatest amount of milk by the quickest and most inexpensive method. The district where the largest quantity of "balata" trees are known to exist in the colony is that bordering on the Correntyne River, known in Dutch Guiana as the "Nickerie district" and large tracts of land have been given to an English firm to collect balata. Balata is treated by the manufacturers simply as a superior kind of gutta-percha, and therefore its name disappears when manufactured; nevertheless balata is distinctly different from gutta-percha, and this is manifested in some of its physical characters—for instance, it is somewhat softer at ordinary temperature and not so rigid in the cold. Besides the bullet tree, there are trees or plants known as the *Tonekong*, which gives a valuable rubber, and again *Bartabulli* and *Bushrope*, to which collectors do not appear to have given a name. The indiarubber balata industry, although carried on in the colony of Dutch Guiana in a desultory way for a long time, has never until quite recently assumed sufficient importance to cause the local government to legislate upon it. As yet the law only lays down the regulations under which concessions are granted, and does not deal with the supervision or treatment of the trees, or the method of extracting the milk. Caoutchouc or indiarubber is yielded both by trees and vines. Those already mentioned are, as far as it is known, the principal ones in the colony, and the method of collecting the milk is by cutting down trees, by incisions, and by circling the tree. In each case there is no protective law, and the trees are generally ruined. The chief port of export is Demerara, and as yet no export duty exists, but as the production increases it is expected that it will not escape taxation. Nothing has been done to cultivate the plant, neither does the soil seem to favour its growth except in some peculiar circumstances. Consul Wyndham says that now laws are contemplated for the leasing of lands to prospect for balata. An article on the "Balata Industry," taken from the report of Mr. G. S. Jenman, Government Botanist, British Guiana, will be found in the *Journal*, vol. xxxii, p. 92 3.—*Journal of the Society of Arts*.

TEA is called by some physiologists a "savings bank," in which tissue is preserved. Tea is classed by scientific men as coming under the head of paratriptics, a class of substances which serve to prevent waste in the body, so that by their help and stimulus greater privation can be endured and more work accomplished. Coffee and Tobacco come under the same classification.—*American Grocer*.

THE PLANTERS AND THE CHICAGO EXHIBITION FUND.

The following is a copy of the circular that is being sent round the Dimbula district, and we reprint it for the benefit of the planting community in general. The amount estimated as likely to be given by the Colombo mercantile community has already been considerably exceeded; so that the planters should do their best to try and make up even more than the sum put down here as their quota. The Agrapatana planters are setting a good example, their list including R200 from Mr. Wm. Mackenzie, R200 from Mr. Ashton, and R250 from Mr. Seton. We would draw special attention to the statement that "the measure of usefulness attained depends upon the balance left over after all initial expenses are paid." Let Ceylon aim high and act accordingly.

Resolution passed at the Dimbula Planters' Association on November 6th, 1891.

"That in the opinion of this Association the Chicago Exhibition should, in consideration of the great importance of gaining a footing in America for Ceylon Tea, receive the support of every member of the Planting Community; and it is earnestly hoped that the members of this district at any rate will subscribe liberally, either through the Ceylon Tea Fund or by special subscription, towards the Exhibition."

The Committee appointed to collect subscriptions in Dimbula is of opinion that it cannot do better than quote the words of the Chairman of the Planters' Association in his circular to non-subscribers to the Tea Fund:—

"I appeal to you not to leave it entirely to others to supply the necessary funds. I cannot but feel that those who have subscribed to the Tea Fund throughout have been somewhat ungenerously treated by those who do not subscribe, since the benefits reaped—and of these there can be no doubt—are reaped by non-subscribers equally with subscribers. I ask you, therefore, with confidence to contribute a special donation towards the Chicago Exhibition Fund, and I would suggest for your consideration that this should be based on the rate of $\frac{1}{4}$ of a cent per lb. made tea for the current year."

The Committee would point out that in this district alone there are over 80 estates which have not hitherto subscribed to the Fund, and earnestly treats the consideration of owners or managers of such estates to the extreme urgency which has called forth the above appeal.

The mere fact that our Teas are falling in price at this season—although quality is wired good, consumption of Ceylon tea is increasing, and stocks decreasing, in England—points with irresistible conviction to the conclusion that the trade is possessed with the idea of imminent enormous over-production. One authority at home, writing last month, estimates the production of India and Ceylon Tea in 1891 at 300,000,000 lb. Without agreeing with this estimate, it must be apparent to all that it is absolutely necessary to endeavor to open up new markets, and such an occasion as the Chicago Exhibition is not likely to occur again for many years.

The Committee would point out the success already attained in Australia, where almost 9,000,000 lb. of India and Ceylon tea will be consumed this year, all of which would otherwise have found its way to swell the stocks in England.

Considering the vast extent of the Exhibition, covering as it does 300 acres, and the efforts all nations are making to secure adequate representation, the Committee is of opinion no time should be lost in arriving at a knowledge of the amount likely to be at the disposal of our Commissioners. Upon this depends the amount of space for which Ceylon can apply. It has been said that £10,000 is the very lowest sum with which a start should be made. But the Committee would point out that for £15,000 not only 50 per cent. more could be done, but many times the number of

people attracted, as the measure of usefulness attained depends upon the balance left over after all initial expenses are paid, such balance to be expended in advertising, covering expense of a Ceylonese band, or in the many other ways necessary to conform to the American methods of drawing attention to specialties.

With £20,000 the degree of usefulness might again be enhanced many times. For an object so vital to our existence as Tea Planters, it should not be difficult to raise £14,000 (leaving the Government and the Tea Fund to make up £6,000) from dependents on an industry covering 240,000 acres. It amounts to 1s 2d per acre or two-thirds of the monthly cost of weeding.

The Committee would suggest that the above sum (£14,000) may be raised, provided subscriptions be apportioned somewhat as follows:—

	R.
Supposing Estates which have not contributed to the Tea Fund give R1 per cultivated acre—say, 100,000 acre	100,000
Special subscriptions from estates which have paid, Superintendents, and Assistants	50,000
From Agents, Brokers, and Shippers	12,500
Donations from wealthy natives (who are to be asked to subscribe by Hon. L. H. Kelly)	12,500
	185,000

The Committee suggest the above merely to show what an average subscription should be; not doubting, however, that many hitherto non-subscribers, and even shrewd and far-seeing subscribers, will contribute largely without respect to average.

The Committee would point out that Dimbula, being the first district in which subscriptions have been started, as well as the largest in the Island, the degree of liberality displayed here is certain to be the measure of the liberality of other districts. For this reason a sense of responsibility rests upon Dimbula Planters.

In proportion to our area, our share of the total should be R25,000, or about R140 from each estate, and its European staff.

The Committee hopes every man will do his duty.

NOTES FROM OUR LONDON LETTER.

CHINA *versus* INDIAN TEAS—MORE ACCOMMODATION FOR CEYLON TEA SALES—LANKA PLANTATIONS COMPANY—LOSSES FROM CHINA TEAS.

LONDON, Nov. 27.

There is very considerable excitement shown here respecting a statement made by Sir Andrew Clark recently when lecturing to the students at the London Hospital that he considered China teas to be infinitely less harmful than Indian teas. By making such a statement Sir Andrew Clark has thrown out a challenge which is being freely taken up by the London newspapers, as well as by many of those published throughout our provinces. My space would not admit of my quoting the many extracts that might be made from these. We suspect that it will be found that the distinguished *medico* has got his head into a hornets' nest. It seems to be the generally entertained view that it is quite impossible, as well as unfair, for any medical man to formulate a proposition as to the relative wholesomeness or otherwise of various teas which could hold good in all cases. As one man well qualified to judge remarked to me:—"Indian and Ceylon teas are both of them stronger than China. It may be that, the condition, of infusion being in all cases the same, the China teas might suit some of the weaker stomachs better than Ceylon or India; but if either of the last were dealt with as they should be in such case, and the tea only allowed to draw for say three minutes

at the very outside, the result would be no difference in the constituents of the liquor, while the superior flavour of the Ceylon would still remain manifest."

Now this, we think, would have been a fair way for Sir Andrew Clark to have dealt with the subject. It is manifestly quite the reverse for him to have condemned as inferior certain growths of tea, which, if dealt with according to circumstances, would yield exactly the same results that he asserted to be so beneficial in the use of China tea. No doubt a good many of his younger professional brethren may follow the lead that has been set by Sir Andrew, and a deal of harm may follow. In a letter from Sir William Gregory shown to me this week, he recommends that the Ceylon Association should take the matter up. He wrote that he thought the statement made was likely to have a very bad effect if not strongly combated in the papers, and further told his correspondent that a Dr. Little, a leading Dublin physician, was also recommending his patients to drink nothing but China tea. We hear that the Tea Committee of the Association had Sir William Gregory's proposition under consideration, but that it deemed that, as Sir Andrew Clark had not specifically mentioned Ceylon tea—though doubtless he had intended to include it under the category of Indian—it was scarcely worth while for the Association to take the matter up.

It has been mentioned above that the references to this topic by the Home Press are too numerous for notice here, but I should like to quote the following from *Trade and Finance* because it agrees so well with my own former experience and those, it is quite certain, of many other tea drinkers:—

Sir Andrew Clark, in a recent lecture to the students of the London Hospital, informed them that the proper quantity of tea was one spoonful to each person and one for the pot. Who does not know this? As for his very strong condemnation of Indian tea, and the statement that a cup taken early in the morning "disorders the nervous system and induces a state of tea intoxication and nerve disturbance most painful to witness," like most such sweeping assertions, it is not founded on fact. The writer was for six years in India, and every morning during that time—2,190 mornings—took one, and often two cups of Indian tea for his *chota hatti*, besides what he may have drunk at breakfast and in the afternoon, and his nerves are still unshaken. Of all the hundreds of people he knows who do the same, he has never seen one intoxicated from Indian tea.

Too much tea, either Indian or Chinese, is probably bad for anyone predisposed to nerve disorders. A man in the position of Sir Andrew Clark should be especially careful not to be carried away in the heat of oratory. His remarks are calculated to unnecessarily prejudice many against the tea of India.

The resolution arrived at by the Tea Committee of the Ceylon Association in London to address the Tea Brokers' Association on the subject of inefficient accommodation for Ceylon tea sales has led to the receipt by it of a letter from the latter body dated 23rd November, informing it that a special general meeting had been called, and that the following resolution had been adopted at it:— "That this meeting is of opinion that a further Ceylon tea sale should be held on two days, at least, during the week, and that the Brokers' Association approach the Directors of the London commercial sale-room without delay to request them to set aside a special room for that purpose."

If the request of the brokers above indicated be complied with, it is probable we shall hear of no further difficulties of the kind which have lately been so fully discussed. This will not, however, altogether relieve your planters from the necessity of giving their

brokers more time between the arrival of their teas and these being put up for sale. It is quite impossible under present conditions insisted upon that the breaks of tea can be properly judged of by intending buyers. One day cannot suffice for all of these to taste the teas, even although, by the yielding of a separate room and a second day, the pressure will be very materially reduced.

With this you will receive copy of the report of the Lanka Plantations Company, which is to be presented to the shareholders at their general meeting to be held on December 2nd. You will find it to be a document, when consideration is given to all the circumstances, of a very satisfactory character. The Company seems at length, and after many years of arduous working, to have turned the course of the difficulties which have so long beset it, and now by far the larger area of its proportion is under tea cultivation and yielding well. You will note, however, that 755 acres are still under coffee, and that efforts are being made to retain so much of this as promises to repay high cultivation. During the year to which the report refers this coffee area seems to have done well, though some of it certainly has given but a poor return. Taking it all round, barely 3 cwt. per acre was secured; but some estates, no doubt, such as are referred to in the report, gave a very much higher average. Fortunately the price obtained throughout the year was good, and altogether a sum of £9,608 was obtained from this source. Of cinchona 61,905 lb. was shipped, but for this only £731 was obtained, and no effort was made either to maintain or extend this particular cultivation. Cacao is reported most favourably of, and some of the estates owned by the Company seem to be particularly well adapted to the growth of the plant. So much is this the case that the directors are anxious to widen the area now devoted to it, but they state that their capital is insufficient to do this effectively, and ask the shareholders to subscribe additional debenture capital for the undertaking. £5,071 was obtained from this item. Of tea, the estates yielded from 1,666 acres 248,574 lb. This sold for £9,627, an average of about 9½d per lb. net. The total acreage of the Company's nine estates is 4,097½ acres. The proposals of the directors as regards dividend justify what has been said above as to past difficulties being now surmounted, and the profit and loss account has warranted them in recommending a dividend of 6 per cent on the preference shares and of 5s per share on the ordinary shares. This second dividend might have been made at a rate of nearly 4 per cent, but that the directors wisely thought it desirable to write off a sum of £110 for depreciation on machinery account and to reduce the suspense account by £1,427. The dividends recommended will be paid free of income tax.

A friend interested in the China tea trade having recently described to me the methods he has seen adopted in the preparation of green tea and the prices realised here for the finer qualities, I was induced to ask a gentleman well up in all matters respecting Ceylon tea if any effort had been made to send home similar teas from your island. He told me that some 18 months back a very fine lot was received, and that it fetched a high price at the sales. Perhaps that price was too high, for the purchaser was unable to dispose of it to the retail trade save at a heavy loss. The result to the first venture having proved so good to the shipper, orders were wired out to send home more of the same sort, but the buyers had taken alarm, and when the fresh lot was put forward there was scarcely any bidding at all. In the

course of time, however, the purchaser of the first lot not only sold off all he had bought but found fresh demands made upon him for a further supply. This he now finds himself unable to obtain, the manufacture having been stopped by orders from home. It is questionable, however, if your planters would do wisely to recommence shipping green tea, for it has been told me that the market for it is most precarious. A demand may spring up for a short time and then die away suddenly, and any attempt to supply so capricious a market would almost certainly result in disappointment. There is no doubt that the prices obtained for the first shipment could never again be got. From all I can learn, it appears to be the case that all the green tea coming from China is more or less coloured, some of it so thickly that the scum can be taken off the infusion with a spoon; others so delicately that not a trace is observable on the surface of the hot water. The Chinese are said to be remarkably skilful in the manipulation of the colouring matter. A man will take a handful of this, and with it stir up a quantity of tea leaf with such judgment and deftness that not a single leaf will remain uncoloured, and not one with more than its due proportion.

The state of the China tea market is, it would seem, a ruling factor just at present in paralysing all business on the Stock Exchange. At least the *Echo* seems to think this. That paper has declared that the losses this year in dealings connected with China tea have amounted to no less than £750,000 and that until the embarrassment caused by this loss has disappeared, the present difficulties of the Stock Exchange must remain and speculation be slack and dangerous. And yet we have not heard of any serious failure among the firms which deal mainly in tea from the Celestial Empire. There is, however, probably some basis of truth for what the *Echo* has stated, though it may be doubted if the loss has been as that it could have the effect mentioned on such enormous transactions as those of the Stock Exchange. Still, of course, the loss must mean diminished capital in this country to the amount, whatever it may be, of the losses if sustained.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the "Ceylon Tea Fund" held within the Planters' Association's Rooms, Kandy, on Friday, the 11th December 1891, at half past nine o'clock (9.30 a.m.) in the morning.

Present:—Mr. Giles F. Walker (Chairman, Planters' Association of Ceylon), Messrs. W. D. Gibbon (Kandy), T. O. Huxley (Kandy), W. S. Thomas (Chairman, Dimbulla Association), A. M. White (Kandy and Kelibokka), A. W. S. Saokville (Chairman, Maskeliya Association), Sholto G. D. Skrine (Chairman, Dikoya Association), T. O. Owen (Kandy), John Aymer (Honorary Secretary, Dolosbage and Yakkessa Association), A. E. Wright (Maskeliya), L. Stuart (Chairman, Dolosbage and Yakkessa Association), A. G. K. Borron (Kandy), Hon. L. H. Kelly (M. J. C., Kandy), Messrs. Wm. Forbes Laurio (Kandy and Kurunegala), A. Phillip (Kandy, Secretary to the Planters' Association, of Ceylon).

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee of the "Ceylon Tea Fund" held at Nuwara Eliya on Friday, the 9th October, were taken as read and were confirmed.

CEYLON TEA FUND SUBSCRIPTIONS.—Read letter from Mr. A. G. Lizard, Detonagala Estate, Bogawantalawa. Read letter from the Honorary Secretary, Dikoya Planters' Association. Read letter from the Chairman, Dimbulla Association. Read letter from the Honorary Secretary, Maskeliya Association. Read letter from the Chairman, Knultera Association. Read letter from Mr. Robert Young, Benvenla Estate Wattogama, intimating

that from 1st January 1892 his estate will subscribe to the "Ceylon Tea Fund." Read letter from Mr. George Beek, Henfeld, Lindina, enclosing cheque to Ceylon Tea Fund, and inviting attention to his proposal to increase the rate of subscription to the Fund on the ground that the funds at present available are far too small for the vast undertakings before the Committee. Read letter from A. Bethune, proprietor Madooltenne, Veyangoda, intimating that it is his wish that the estate should subscribe to the "Ceylon Tea Fund" on the usual terms. Read letter from R. Innes Berry on behalf of Mr. Thomas J. Liptona' Peoprasio group stating that he has been instructed to notify that the subscription is discontinued from date. Read letter from Messrs. J. M. Robertson & Co, Resolved:—"That the letter be acknowledged." Read letter from Mr. A. H. Mallet intimating that the proprietor of Ruanwella estate would subscribe to the "Ceylon Tea Fund" in 1893.

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.

NOMINATION OF A COMMISSIONER.—Read letter from Mr. Morey, United States Consulate of Ceylon, enclosing copy of his letter to the Hon. Geo. R. Davis, Director-General, Columbian Exposition 1893, Chicago. Read letters from Messrs. W. M. Smith & Co, Walter Agar, H. F. Dunbar, J. M. Macmartin, J. A. Roberts, A. Rossio Ashton, Thos. Dickson, Junior, James Westland, F. J. Whittall, P. E. Radloy, J. Manley Power, Arthur Anson, Chas Ogilvie, W. Lamy Smith, Reginald Ellis, L. B. H. Dickinson, E. R. Wiggin, H. W. Hornby, R. B. Hector, W. Harman, J. H. Wynell-Mayow, F. D. S. Amarasuriya, E. V. Carey, E. de Foubleanque, H. D. Deane, E. Rodwell, Walker, A. M. Ferguson, Junior, and Honorary Secretary, Dikoya Association.

Resolved (1):—"That the nomination of the Hon. J. J. Grinlinton as a Commissioner to represent the planting interests of Ceylon at the World's Columbian Exposition, Chicago 1893 meets with the approval of the Standing Committee of the Ceylon Tea Fund and that the Chairman do submit his name for approval at the general meeting of the Planters' Association of Ceylon to be held this day."

Resolved (2):—"That the sum of £30,000 granted towards the Chicago Exhibition be raised to £35,000 and that the half yearly instalments be made accordingly."

CEYLON TEA IN RUSSIA.—Read extract of letter from the Secretary, Ceylon Association in London, on the subject.

CEYLON TEA IN VIENNA, PRAGUE, KARLSBAD &c.—Read letter from Mr. John Ferguson of the *Ceylon Observer* making suggestions as to further pushing the sale of and making known Ceylon Tea in Vienna, Prague, Karlsbad &c. Resolved:—"That the Standing Committee of the Ceylon Tea Fund do convey to Mr. John Ferguson their thanks for the interest he has taken in pushing Ceylon Tea in Austria, and inform him that his recommendations will receive full consideration."

CEYLON TEA IN ITALY.—Read letter from Messrs. Whittall & Co. notifying that the Tea for presentation to Her Majesty the Queen of Italy (100 lb. finest Ceylon tea packed in two ornamental half-chests—one of eilandamer and the other of tamarind wood) had been handed to Mr. Geo. Vanderspar, the Italian Consul. Read letter from Mr. George Vanderspar intimating that the tea had been duly shipped.

CEYLON TEA IN GERMANY.—Read letter from Mr. Shelton Agar enclosing a letter from Mr. E. Schrader on the subject of further pushing the sale of and making known Ceylon tea in Germany. Mr. E. Schrader addressed the Committee on the subject. Resolved:—"That a special meeting of the Standing Committee of the 'Tea Fund' be held in Kandy on Monday, the 4th January 1892, at 3 o'clock in the afternoon, to consider the question of a subsidy of tea to Mr. Schrader."

ANALYSES OF SAMPLES OF CEYLON TEAS.—Submitted letter from Mr. H. Atkinson. Resolved:—"That its consideration be postponed to next meeting."

CEYLON TEA AT THE KIMBERLEY EXHIBITION 1892.—Submitted letter from the Secretary Ceylon Chamber of Commerce.

NEW ZEALAND AND SOUTH SEAS EXHIBITION.—Submitted letter to the Government Agent, Western Province, dated 10th November 1891, transmitting to him Bill of Lading duly endorsed in his favor for a case said to contain fancy goods referred to in the extract of the letter received from Lord Onslow, Governor of New Zealand, and requesting an acknowledgment which, however, up to date has not been received.

PURE CEYLON TEA.—Read letter from Mr. Geo. J. Jameson submitting proposal for introducing and pushing the sale of pure Ceylon Tea in Manchester, and the Lancashire districts generally. Received:—"That the Standing Committee of the Tea Fund would recommend to the General Committee of the Planters' Association of Ceylon that Mr. Jameson be recognised as an agent of the Planters' Association of Ceylon for the sale of pure Ceylon Tea in Manchester, and the Lancashire districts generally."

The Standing Committee of the Tea Fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon:

NOTES ON PRODUCE AND FINANCE.

LOSSES IN CHINA TEA TRADE.—*Apropos* of our remarks on this subject last week, the *Financial News* says:—"For a long time the China tea trade has been in process of displacement so far as England is concerned. Although our consumption of tea has enormously increased during the past ten years, it is mainly Indian tea that we consume. China has had to send its produce to Russia, although mostly by way of Mincing Lane; but now there is a curious change apparent in the course of this trade. Either Russia is importing less tea—which is doubtful—or it is importing more from China direct. It is said that the losses of English speculators in the China tea trade have, thanks to this cause, been enormous during the past twelve months. The figure is even put as high as £750,000."

LAST WEEK'S TEA SALES.—"So far as it relates to Indian tea," says the *Grocer*, "the process of deluging the market with supplies seems to go on apace, for, notwithstanding the unheeded quantity put forward since the early part of October, the total amount offered by auction during the present week has embraced no less than 39,830 packages, which, strange to say, and despite the excessive preponderance of inferior qualities, have been taken off, and that, too, without signs of such exhaustion on the part of the dealers in their efforts to clear the market as were apparent a short time back. With such an enormous supply as the above to handle in two or three days, it is no matter for surprise that there has been some unevenness in prices; but, admitting that the tendency here and there has been rather against the seller, it has been chiefly for poor low stuff which hardly deserves the epithet of tea, and with these and one or two other unimportant exceptions the auctions have had a tolerably favorable result. The grades that have seemed to engage most attention have been leafy Pekoes, which at 9d and over are unmistakably cheap, and the only wonder is that the trade in the country are not fully awake to the discovery. Really fine teas are scarce, and realize firm rates. Smaller supplies of Ceylon tea have come as an unmitigated relief to the market, and the irregularity of last week's prices has disappeared. Quotations have shown no recovery, sellers having to buy in when offers were too low to accept, and common grades constituting the chief supply, tend to prevent any appreciable improvement in values, especially as Indian teas of a similar character enter sharply into competition. The *Produce Markets Review* says:—"There has been no falling-off in the demand for Indian tea. The quantity brought forward has not been excessive, and there was a hardening tendency at the earlier sales for the good common sorts. These teas offer better value than for a considerable time past, and the trade are not slow to take advantage of this, as is shown by the freedom with which they are buying. A slight check in the demand, however, is not improbable during

next month, but if the importers regulate the supplies, and avoid weighting the market too heavily, prices may remain steady. The medium kinds of both whole and broken leaf have been well bid for, at steady, and in some cases rather firmer, rates. The finest kinds continue to sell readily, and as they are not too plentiful, they command high prices."

THE COFFEE MARKET.—Discussing the position of coffee, Messrs. Wilson, Smithett and Co. say:—"The position of this article has altered but slightly since the date of our last. The attention of the trade is still fixed on the political crisis in Brazil, as in the event of serious disturbances there, which would delay the shipment of Rio and of Santos coffee, the long-continued scarcity would extend into the New Year; and with exhausted stocks in every port a rapid appreciation of value would probably take place. It is expected that difference will be peaceably arranged, and confidence seems more general; the most recent daily receipts are also on a larger scale. In this market great scarcity prevails, and all grades show a further advance. The speculative markets have shown excitement during the past fortnight, but business was of small extent, although quotations fluctuated considerably.—*H. and C. Mail*, Nov. 27."

THE RETICULATED OR SPONGE-BEARING CUCUMBER.

Under the name of "Luffa," or "Cucumber Sponge," we now import in compressed bales, from Japan and Egypt, the reticulated skeletons of two varieties of what Ebn Baitar, the Arabian botanist, twelve hundred years ago described as the "Luffah," taking his title from the Egyptian name of "Luff." Dr. John Veslingius, of Holland, in 1638, in writing a work upon the plants of Egypt, as a sequel to that of Prospero Alpini, describes, with two engravings, the Cucumber-plant that now furnishes the commercial Luffa of Egypt, under the title of *Luffa Arabum* or *Cucumis reticulatus Aegyptius*. The Japanese and Egyptian commercial varieties so closely resemble each other that the pictures of Veslingius, which were taken from plants grown by himself, are excellent representations of the Japanese *Luffa macrocarpa*. Had he cultivated the Japanese variety, which comes to maturity much earlier, he would not have fallen into the error of describing the seeds as white instead of black. From a very early period the reticulated skeletons of *Luffa Arabum* were used by the Egyptians in their bath-rooms, and it is probable that the Japanese did the same with that of the *L. macrocarpa*.

Sponge-bearing Cucumbers may be found in a large number of hot countries, and vary in size from that of a plum to three feet in length. In some the skeleton is very thick and strong, and capable of being made of use in the household, but in the majority the netting is thin and delicate, and can only be regarded as a curiosity. Like ordinary Cucumbers, some are edible and are grown for the table, while others are more or less medicinal, and are used as domestic remedies. As the reticulation forms at a late period, the Luffa, when of an edible sort, can readily be cooked as a vegetable when young; the rank odor of the fruit would be an objection to its use with us, but this has not availed much against the tomato.

But little attention has been paid by botanists either ancient or modern, towards collecting, arranging and describing the class of cucumbers which is distinguished by bearing a subterraneous or a complete internal skeleton. Under the name of Momordica, Cucumis, Pepo and Luffa we may find several varieties described in old botanical works, chiefly in Latin, Dutch and French; and may also discover that several, as the *Luffa Petala*, *L. acutangula*, *L. Aegyptia*, etc., have been very correctly represented by large plates.

The Luffa is fully entitled to membership in the Cucumber family, and is in no sense a Gourd, as it has sometimes been called. It is unnoctuous, having separate staminate and pistillate flowers, of which the former are much the larger, or more conspicuous; and the leaves much more closely resemble in form those of our common cucumber than do many in Egypt, Palestine and India, upon

plants producing the best table varieties, some of which are much more like Cantaloupe-vines than Cucumbers, as we know them.

My first trial in growing Luffa-seeds was a failure, because I made the attempt with a variety that required so long a season in which to perfect its net-work, that frost came, even before it had begun to form. The fruits grow half a yard in length, and the vine was vigorous, but the season required was too long for this latitude. My second venture was with the *L. macrocarpa* of Japan, which produced fully matured fruits in five months from the day of planting. This is the best sort to grow in a temperate climate, and bears the most symmetrical of all the sponge cucumbers; the fibre of the netting is coarser than that found in the Egyptian variety, and not so well adapted for use as a scrubber in bathing. *L. macrocarpa* bears cucumbers from thirteen to fifteen inches long, and some of them are very nearly straight. The vine is a vigorous grower, and, in favourable seasons, a fair crop of cucumbers. In very dry weather there will be a scarcity of pistillate flowers until after a supply of rain, when they will appear in almost every joint. The cucumbers develop rapidly, and, but for the slow growth of the vine in the early season, would come to maturity in large proportion; as it is, however, there will be many fruits that will only be partly grown when frost arrests their development. Much time may be saved by having the plants grown a yard or two in height in a greenhouse, and then setting them out on the 10th of June; as the plant is tropical, it will stand the full heat of the sun all day without drooping, and grow all the better for it. My best success came from planting against a trellis on the south side of a wooden building, with an all-day exposure to the sun.

Next to *L. macrocarpa*, the wild Cuban does the best in Philadelphia, as it comes to maturity early, and grows much larger than in its native island. The Egyptian variety grows well and sets many fruits; but these are late in maturing, so that as yet I have not produced any with black seeds. The Petola I have not tested yet; it looks promising in its picture, and is one of the few that produce a good reticulation. A hybrid between the Japanese and Egyptian varieties might readily be produced with a brush, and, theoretically, should be finer than the Japanese in its netting, and shorter-season than the Egyptian. Hybridization should be produced each way between the two parents, and plantings tested with seeds from several experiments, as this way of producing new varieties has much uncertainty in its final results.

The first Luffa sponges sold in this city were grown from Cuban seed; the second came from Japan, and the third from Cairo, in Egypt. Japanese seed were grown in Louisiana before there were any sponges of *L. macrocarpa* for sale here, and my first stock came from that state. Under the name of the Bonnet Gourd and Dishcloth Gourd, this and the Cuban Luffa are now well known in several of the southern states, although, as I have stated, the name of Gourd is a misnomer. Bonnets are sometimes made from the opened sponges, shaped out with some woven fabric, but the entire head-covering was not produced of the net-work until the large white Luffas of Egypt furnished the material for cutting and fitting.

The *Cucumis reticulatus* of Egypt is grown in large quantities, and has become quite an article of commerce, being exported mainly to England and Germany, the packages containing 1,000 to 1,500 each; but a small proportion of these are sponges of the whiteness and quality that indicate a proper care in preparation. When a sponge cucumber is dried whole the netting is easily separated; but its fibre will have a brownish color and will have lost much of its tensile strength. Naturally, the reticulation is of silvery whiteness, and this can only be preserved by a proper method of cleaning it from rind, seeds and pulp when the cucumber is matured, but still green; and the whole must be done at one operation or the sponge will change in color. When a Luffa has reached its maturity of

growth it will be known by its green rind lightening in color and becoming more dry; it should then be cut off and hung up in the house for a week or more until the juice in large measure dries out of the rind. The cucumber should then be pared and the cap at the lower end removed, which will open the seed channels; it should then be kneaded and squeezed under a large pan of hot water until the seeds and pulp are washed out. When fully ripe the seeds are jet black, and will number from 400 to 600 in very large fruits. When the reticulated skeleton has been well cleaned, hang it up on a pin-hook and string to dry in-doors, when it should become of silvery whiteness and weigh three-quarters of an ounce to an ounce.

By exposure, to the air, even when kept in darkness, the whitest Luffa-sponges gradually change to a light orange-yellow. This color is largely soluble in hot water with soap, and much of it may be washed out, leaving the fluid of a decidedly yellow tint and the sponge much lighter in color. Sponges in frequent use become of a light grayish white tint and slowly weaken in fibre, particularly in the outer or circular layer, which is not so tough as the internal longitudinal one. The sponges are quite durable when compared with those obtained from the sea, and are odorless when well washed; no fabric when wet has as decided an effect as a rubefacient upon the skin, and care must be taken that it does not take too deep a hold where the surface is young and tender. For delicate skins and children the immature skeletons should be selected, or the small end of the mature ones, which is much finer in fibre than the base.

My record of varieties in the *Cucumis reticulatus* amounts to twenty, and these belong to Japan, Moluccas, China, India, Africa, Spain, Cuba, Brazil and Mexico. The tests thus far made go to show that but very few of the varieties will perfect fruit in this latitude, and that it is useless to grow the others, except for ornament or curiosity. The *Macrocarpa* stands at the head of the list, as it has been repeatedly grown; the *Acutangula*, as a curiosity, grown equally well; the Cuban comes to perfection; and by starting under glass, the Egyptian may likewise; the *Petola* and *Mexicana* are yet to be tested in a favorable season. Some others have grown well, but the character of the cucumbers does not make their propagation desirable.

The plants designated are quite ornamental and interesting, with their beautiful leaves, large staminate flowers and hanging fruits, some sometimes as high as a second-story veranda. The Egyptian flower is about four inches in diameter, and others are nearly as large. The staminate-buds grow in bunches and bloom singly, so that the vines are constantly in flower; all of the blossoms are a bright yellow. The pistil of the productive flower develops into the point of the cucumber, and the long ovary into the fruit, the sepals of the blossom long remaining attached.—Dr. R. P. Harris before the Pennsylvania Horticultural Society.—Garden and Forest.

◆
 WHY DO WE STIR THE SOIL?—If compacting the soil make it retain moisture, why do we advise frequent stirring of the soil in times of drought? The question is a legitimate one, and we will answer. It is necessary to plant seed near the surface, especially in the spring, for the soil is warmer there and the conditions of germination more readily supplied. But after the seeds have germinated, the roots strike downward and the moisture is supplied largely by the soil water rising from below by capillary attraction. If the surface is left hard, then the water will ascend to the surface and be rapidly evaporated. But if a steel rake or hoe is frequently used to stir an inch or two of the surface, it breaks the capillary tubes and the moisture ascends to the roots of the plants and there stops until absorbed by the roots and reaches the air by passing through the cells of the roots and plants and leaves, depositing the dissolved plant food by the way.—*Queenland Planter*.

MARKET FOR TEA SHARES.

To the Editor of the *Home and Colonial Mail*.

Sir,—The attention of my Board has been called to a statement in your issue of 20th inst. under the above heading, in reference to an offer for this company's property having been unconditionally refused by the directors.

The facts are:—Two offers were received, and both the offering companies were informed that the offers would be submitted to the shareholders, but before this could be done both were withdrawn. I shall be obliged by your inserting this correction in your next issue.—I remain, sir, yours &c.,

EDWARD CARTER, Secretary.

The Wilton Tea Company of Assam, Limited,
27, Austin Friars, London, Nov. 25th, 1891.

THE INDIAN TEA COMMUNITY.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL"

Sir,—I notice that your correspondent, Mr. D. F. Shillington, responds, in your last, to my letter of the previous week. My remarks had reference, not so much to matters such as Mr. Shillington alludes to, as to others bearing a wider bearing such as the questions of opening new markets and generally pushing the merits of Indian tea. I am fully in accord, however, with Mr. Shillington as to arranging upon a better basis the sales in Mincing Lane, which are now so very large. I believe most persons engaged in the trade, whether importers and growers on the one side, or dealers and buyers on the other, are agreed that it is merely a matter of arrangement; unless, however, there is some pulling together and co-ordinal co-operation amongst the principal parties controlling the trade, it is manifest that things will go from bad to worse, very much, as Mr. Shillington points out, to the detriment alike of buyer and seller. Last year at the urgent call of the most goodly representatives of the large importing houses and companies, a sub-committee was appointed by the Indian Tea Districts' Association to deal with this matter, and an instruction to them was to arrange with the Mincing Lane "broking" firms to formulate some scheme which would obviate the present rather suicidal system (or, rather, lack of system) which prevails. Unfortunately, the "broking" houses, powerful though they are, appear to have altogether failed to accomplish what was required. It is inconceivable how this has been the case, and the failure to effect the desired object points as its cause to party jealousy among the "broking" houses very unworthy of the standing which they occupy. Perhaps it may put some of them "on their mettle" to know that quite recently proposals have been made in certain quarters for the formation of a co-operative selling agency among the importing houses, which, if really carried out, would probably result in doing away altogether with the necessity for the presently-existing broking houses.

I do not mean to say that such a scheme is just at present practicable, nor even desirable; but I allude to it in order to impress upon the "broking" fraternity that owing to the lack of combative power which appears to exist among them, a scheme of this sort is actually "in the air," and is regarded in certain quarters as not only possible but quite feasible.

Before tea importers are driven to such a course, surely the large "broking" houses, whose usefulness the importers are quite ready to recognise, will be able to find some method whereby the present difficulty can be overcome and the necessity for such a step altogether avoided.

What Mr. Editor, I would ask, is the so-called Brokers' Association doing that it permits a scheme such as this, which would practically out-weigh the ground from beneath the feet of the whole Mincing Lane broking fraternity, being every mooted?—I am, Sir, yours &c.,

London, Nov. 25th.

OBSERVER.

SUPPLIES OF INDIAN AND CEYLON TEAS.

Judging by the correspondence in our last two issues, it is evident that the future supply of Indian and Ceylon teas is causing both buyers and sellers to look forward with some degree of apprehension. We have always favoured the view that the more the better, and that if it became a choice between Indian and China tea the latter would be displaced rather than the former; but since Ceylon tea has arrived in such rapidly increasing quantities year by year the situation has become more complicated, and all parties are now agreed that the overwhelming power of the English market has been overtaken by such a superabundant supply that unless new outlets can be opened there must be a further decline in values to an utterly unremunerative point. Our contemporary, the *Produce Markets' Review*, makes the following very pertinent observations on the subject:—

"The future development in the production of Indian tea points to a large increase, and according to the figures recently issued by the Indian Tea Planters' Association, it will reach 150,000,000 lb. during the next two years, without any additional increase of cultivation. This coupled with a probable increase of from 30 to 40 per cent in the production of Ceylon tea during a similar period, will give a supply more than equal to the total delivery of all tea, both for home consumption and export, for the past twelve months. Should this take place, and it is certainly not improbable, it will be necessary to open up new outlets for the surplus supply, as otherwise prices must fall to a disastrously low level, which would, however, have the effect of checking production. The export of Indian tea though comparatively small, are steadily increasing, but they will require to be greatly accelerated if they are to keep pace with the increased supplies. Those interested in this industry, therefore, will do well to study both the manufacture of the tea and the likely packages to meet with favour, where the prospects are most encouraging or breaking new ground. Judging of the probabilities of the future export demand, the United States of America and Canada are the countries most likely to show the greatest development. One of the most important considerations is to assimilate the leaf to that of China Congou, as appearance is a leading feature. There is also an objection to the largeness of present Indian packages, and to meet this complaint it will be obviously necessary that a certain portion of the tea, and especially that most suitable for export, should be packed in half-chests containing from fifty to sixty pounds, and at uniform rates."

We see no reason why our own Eastern dependencies should not seek to supply the world with tea. Everywhere in which Indian and Ceylon teas have hitherto found a market, the result has been a certain growth in the demand and a manifest appreciation of the quality. But, we confess, we view with regret the very marked depreciation in the average quality of the tea sent to the London market this season. We cannot think that the best interests of either India or Ceylon are served by unduly increasing the production of what the buyers class as very third-rate. Perhaps this season are probably at the lowest point ever seen, and we must admit that never in our recollection have we seen such an undue proportion of undesirable tea offered. There has, no doubt, been a steady decline in the generally accepted standard of quality for several years past, owing to competition among retailers and "present" tea shops; but the descent this season has been outstripped, in many cases, the desires of the most hungry seekers after "tea for price." It becomes, therefore, matter for very grave consideration whether it would not pay planters much better to stay their hands somewhat in regard to fresh extensions, and try to manufacture a rather smaller quantity of rather better tea. China tea has been displaced simply because the quality did not bear comparison with Indian and Ceylon growths. But the retail dealer in tea has now acquired a very cosmopolitan taste, and

caree not where in the wide world the leaf grows so long as it pleases his customers. It is, therefore, worthy of the serious consideration of all tea planters whether they will go on aiming at large quantities of inferior quality about which no enthusiasm will be possible, and which will inevitably land the tea-producing industry in another such hog as it floundered out of with such difficulty five-and-twenty years ago, or will they, to use the language of the Malthusians, impose a modified description of preventive check on production, which will raise the standard of excellence in the thing produced and restore the waning prestige of British-grown tea?—*H. and C. Mail.*

THE LAND MORTGAGE BANK OF INDIA, LIMITED.

The extraordinary general meeting of the shareholders of the above Bank, to which we referred last week, was held on Friday, at the City Terminus Hotel, Mr. J. R. Boyson in the chair, in compliance with a requisition to hear a proposal by the requisitionists to the following effect:—"To elect a committee of investigation to enquire into and report on the necessity or expediency of the call of 10s. per share made on Sept. 23rd, 1891; also to enquire into and report upon the management of the bank and future prospects of the shareholders; and for the purpose of hearing any explanation the directors may have to offer." The chairman, in opening the proceedings, stated that the only object of the meeting, and the only question they had to decide, was whether there should be a committee of investigation to look into the conduct of the directors for the past twenty-three years. A most unfounded attack had been made on the board, who had done a great deal for the shareholders, and he alleged that a persistent attempt had been made since 1831 to wreck the bank. The beginning of the affair was in that year, when Mr. Stewart, the then manager of their tea estates in India, happened to be at home on short leave. Unfortunately for the bank their manager had allowed himself to be tampered with by Messrs. Buchanan and Muir, who at the time had not a farthing of interest in the company. Mr. Buchanan remarked that he was a shareholder at the time. The chairman, continuing, stated that there had been an attempt ever since 1831 to get the affairs of the company into the hands of Mr. John Muir. He read a letter marked "confidential," which was sent by Mr. Stewart, dated Feb. 9th, 1883, to Mr. Muir relating to the business of the company and the value of its tea properties and other assets. He afterwards referred at length to the subsequent action of Mr. Buchanan and Mr. Muir, and stated that the shares consequently went down to nil, and their 5 per cent. and 4½ per cent. debentures to a discount. The call had been decided on by the directors after considerable thought. The fact that they had to pay off £14,000 in January had not caused them to make the call, the object of which had simply been to strengthen the credit and the financial position of the bank. Even after making the call he had been in hopes that they would be able to adopt some course which would put a stop to the possibility of any further call. When they had brought their debenture liability down to £160,000 or £170,000, which he was sure they could have managed, he felt that they could go to the holders, point out the position of the company with its uncalled capital of £1,000,000, and ask them to take debenture stock or preference shares, thereby relieving the shareholders from any further anxiety as to calls. When, however, the requisition was received for an extraordinary general meeting to pass a vote of censure on the board's management, he confessed that he had not felt so sanguine of being able to carry out a plan with this object in view. As to the general charge of mismanagement which had been brought against them by the requisitionists, he claimed in view of the facts set out in the circular issued by the board, that this charge could not be sustained, and that, on the contrary, they were entitled at least to the con-

fidence of the shareholders. A certain proposal had been received by the directors from Messrs. Finlay, Muir & Co.; but it could not be dealt with at that meeting, which had been called for a specific object. After reading the letter containing the proposal—which was to finance the bank for the next five years without making any call—the chairman read the reply which he had made to it, stating that if it had been received sooner, and supplemented by additional information, the directors would have deemed it their duty to submit it to the consideration of the shareholders in general meeting; but that as the directors had almost concluded an arrangement with Messrs. George Williamson for their assuming charge of the estates in question from the end of the current season, on very satisfactory terms, there might be some difficulty in now entertaining Messrs. Finlay, Muir & Co.'s offer. He had had a long interview on the previous day with Mr. John Muir, to whom he had given the fullest information respecting the affairs of the company. Mr. Buchanan afterwards addressed the meeting at length, entirely repudiating the construction which the chairman had put upon his action, and giving an unqualified denial to the statement that he was working in this matter for his own personal ends and not for the interests of the shareholders. He urged that an investigation was needed to see whether the call was necessary, in view of other courses which had been suggested, and which might be capable of being adopted. The chairman, interposing, said he had foreseen that some of the shareholders might regard the call as a hardship if they had to pay it before the offer made by Messrs. Finlay, Muir, & Co., and other proposals were considered as these might render a call unnecessary; and the directors had therefore determined on issuing a notice deferring payment of the call until January next, or later. Mr. Buchanan said he regarded this as a very gratifying announcement, and added that half of his contention had gone by the chairman having conceded that it was necessary for the company to have an Indian agency. He still, however, maintained that an investigation into the company's affairs was necessary, and that it would be beneficial; and concluded by moving a resolution in accordance with the object of the meeting. After a protracted discussion, the chairman expressed his readiness to accept a suggestion to the effect that the board would take into its consideration seven shareholders holding not less than 1,000 shares each, purchased before January 1st last. Upon this Mr. Buchanan withdrew his motion.—*H. and C. Mail, Nov. 27.*

THE LAND MORTGAGE BANK OF INDIA LIMITED, AND MR. STEWART.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—My name was pretty freely mentioned by the chairman at the meeting of shareholders held on the 20th inst. From the special nature of the business for which that meeting had been called, as well as owing to the time occupied by the chairman's opening speech, it would have been impossible for me to have obtained an opportunity of replying to the structure which he chose to pass on me. I beg to be allowed to do so through the medium of your columns. When I voyaged to Calcutta in November, 1891, Mr. Buchanan led me to understand that he was, at that time, a shareholder in the bank. At the meeting of shareholders on the 26th inst., he specially interrupted the chairman to say that at the time referred to he was a shareholder. The value of this interruption was, that it supported my narrative of what had occurred on board ship; and next, that it enabled many—myself amongst them—to disabuse our minds of any idea of a wilful attempt on the part of that gentleman to mislead me.

At that time I foresaw (as it turns out, only too accurately) what would ultimately befall the bank when the time should come that its Indian realisations would be insufficient to meet

the debenture bonds as they fell to be paid. I further saw that, at such a time, what the bank would require was a strong-backed firm in the position of agents in India. On board that outward steamer I found myself in the company of two gentlemen representing one of the wealthiest tea agency firms in Calcutta, and who, moreover, were known to be on the outlook for further tea business. Under these circumstances I considered myself to be acting for the bank's true interest in reviewing its position with them in order that it might be improved. It is very well to say that I had no authority. Had the scheme produced been carried out in the peaceful way intended, the result would have been beneficial alike to board and shareholders, and instead of being blamed I would, as in another instance where I overstepped my limits of authority, have received thanks for the common sense exercised.

The proposal to have the bank's agency transferred at the proper time to a strong agency firm, has the stamp of the board itself imprinted upon it, for such is now the very scheme which they recommend and which, ten years ago, I foresaw to be a coming necessity. Had this step been taken, say three years ago, instead of waiting till a call was to be made they could have selected their own agents.

I have only to add that the motives assigned to me by the chairman are as ungenerous as they are unfair. The bank's welfare had my first and chief care during the nine years of my service, whilst at the meeting of 20th instant, as well as previously, the chairman held my proxies as a shareholder.—Yours truly,

D. M. STEWART.

London, Nov. 24th, 1891.

COCONUT DISEASE IN JAMAICA.—The Bulletin of the Botanical Department of Jamaica, for September, contains a report by Mr. W. Fawcett, Director of Public Gardens and Plantations, on a disease causing the death, on a large scale, of the coconut palms in the neighbourhood of Montego Bay. The disease first attacks the tissues of the youngest parts. There is no evidence that it is produced by an insect, and Mr. Fawcett considers it is due to an "organized ferment." In the supplement of the *Jamaica Gazette* for September is the remark that the disease is "rapidly destroying the coconut walks in the parish of St. James, and that, if not checked, in a very few years the coconut will cease to be a product of this parish, indeed if not of the island."—*Nature*.

GOOD NEWS FOR COCONUT PLANTERS.—It is said that the Admiralty authorities are devoting their attention to the remarkable properties of a new material, which it is claimed will make an almost impenetrable lining to a ship's sides. This is made of the cellulose of coconuts, which has the property of absorbing eight times its weight of water, and several experiments have been made with it under Government auspices at Portsmouth. The material is made into squares, which are affixed to the interior plates of vessels, and it is asserted that it is extremely difficult to penetrate. It is claimed that the material will work a complete revolution in the present system of ships' protection.—*Colonies and India*. [This statement has been going the round for several years back.—Ed. T. A.]

CHINA v. INDIAN TEA.—A Glasgow correspondent writes:—I notice in your last issue that efforts are being made to bring China tea to the front again. I am dead against this Indian rubbish. I find great difficulty in getting any China—I mean genuine stuff—and especially good tea. When next I go to China I must make arrangements for having the article sent home. Have you any friends in the China tea line in London? I should be so glad to

get a specimen or two of good China tea, and then if price and quality are approved to buy a considerable quantity. Can you help a poor fellow who does not want to be dosed with so much tannic acid as is contained in the Indian article? I am at one with the views expressed by Sir A. Clark on this subject.—*L. and C. Express*, Nov. 27th. [Sir A. Clark is to be congratulated on one's behalf.—Ed. T. A.]

CLOVE AUCTION IN ZANZIBAR.—A Reuter's telegram from Zanzibar, dated November 21st announces that the first public auction sale of cloves, subject to duty, was held there that day. There was a large attendance. Mr. Gerald Portal, the new British Consul-General was present, and stated that it was hoped to make Zanzibar the centre of the trade of East Africa, and that it would probably be declared a free port for imports at the beginning of next year. Public sales of cloves will henceforth be held fortnightly. We understand that the spice trade here are quite in doubt of the results (if any should ensue) which this innovation may have upon the London market. London is now the largest centre for cloves, but yet, if our information is correct, the announcement that public sales had been instituted in Zanzibar came upon dealers here as a surprise. It is well known that the Sultan of Zanzibar derives a considerable proportion of his revenue from an export duty on cloves, and it is surmised that the bulk of the cloves offered by auction in Zanzibar may be those which are said to be sometimes tendered to the Sultan in lieu of cash by exporters. One of Mr. Portal's chief duties is thought to be the reorganisation of the finances of the Sultan, and it is probably in connection with this matter that the sales have been instituted.—*Chemist and Druggist*.

THE TRUTH ABOUT COFFEE.—Notwithstanding the reduction of the duty on coffee and the fact that the best coffee is sold in Great Britain cheaper than anywhere in Europe, it is steadily falling in consumption. There are many theories put forward to explain this. One is that coffee is more adulterated here than on the Continent. This is certainly not the case. It is easier to get pure coffee here than in France, Austria, Italy, or Germany, for abroad it is usually largely mixed with chicory, and is liked all the better for it. The critics who are fond of praising "coffee as you get it in France" are, in fact, praising a heavy admixture of chicory with coffee, which they deprecate here, greatly preferring to have the opportunity of making the combination optional. The next and most common explanation is that we don't know how to make good coffee here. But that again is a fallacy, and its terms a misstatement. We all know how to make good coffee, and there is no one who cannot make it. It is in fact so easy to make good coffee that it is almost impossible to make it badly if only one condition is observed which depends not on the "making the coffee," but understanding the principle of drinking coffee, which everyone understands abroad, and which the travelling Briton performs practices because he has no chance of doing otherwise, and falls in with "the customs of the country." All coffee-drinking races understand very well that the infusion of coffee is not a fluid like tea, to be imbibed in copious draughts. A weak infusion of coffee is a tasteless and almost nauseous draught; it loses all its aroma and delicacy of flavour when dissipated in an ocean of hot water. This is probably due to the fact that its flavour is largely due to empyreumatic oils, which will not bear copious aqueous dilution. The only way to drink coffee in large draughts is to make a small quantity of strong coffee and add to it an ample amount of hot milk; cold milk is out of the question. The small cup of "black coffee" is to be had now everywhere as good in England as elsewhere. But so long as the British coffee drinker persists in treating coffee as if it were tea, and swallowing it by the pint, he will always find that he gets something unpleasing to his palate.—*British Medical Journal*.

THE CEYLON TEA CROP OF 1891.

The exports up to the middle of December closely touched the round number of 63 millions of pounds, the exact figures being 62,918,000 lb. We may, therefore, fairly estimate the total to 31st December at 65½ millions of pounds. Of the quantity already sent away, 58,814,000 lb. went to Britain, and 4,134,000 lb. to other countries, the chief of which were:—

	lb.
Australia	3,022,000
India	427,000
China (1)	162,000
America	158,000
Germany	90,000
Austria	70,800
Africa	69,000
Mauritius	68,700
France	21,000
Spain	17,000
Russia	11,000
Other places, aggregate about ..	20,000

It seems extraordinary that India, which was a tea-growing country nearly half a century before Ceylon was compelled, by the failure of coffee, to enter on the cultivation, should be our best direct customer next to Britain and Australia. There is a taste for our tea amongst many Europeans in India; but the larger portion of the tea exported to India is, doubtless, destined for the Persian Gulf. Still more extraordinary is it that China, which preceded both India and Ceylon by many centuries in the production of *cha*, should now import no less than 162,000 of the fragrant leaf from her youngest rival in the enterprise. But very little of this quantity is likely to be consumed by Chinese. Germany and Austria together, show better than America, which is disappointing while Russia is still more so. We must not, however, forget the exports of our tea from Britain, which are shown in Gow, Wilson, & Stanton's latest report. None, of course, went from Britain to Australia, but to other countries quantities went as follows, Germany, in this case, including Austria:—

	1891.
	lb.
United States	314,127
Canada	353,671
Holland	100,480
Germany	419,640
Russia	49,174
France	34,581
Other places	406,854
Total	1,678,527

Taking exports direct and from Great Britain, the quantities of our teas which will be taken by countries other than Britain in 1891 may be approximately estimated as follows:—

Countries.	Direct.	From Britain.	Total.
	lb.	lb.	lb.
Australia	3,150,000	—	3,150,000
India	450,000	—	450,000
China	170,000	—	170,000
United States	165,000	330,000	495,000
Canada	—	370,000	370,000*
Holland	—	110,000	110,000
Germany	139,800	440,000	579,800
Russia	13,000	40,000	53,000
France	25,000	40,000	65,000
Other places	150,000	440,000	590,000
Total	4,262,800	1,770,000	6,032,800

As over 4½ millions of our exports will go to other countries than Britain and nearly 1,800,000 will be re-exported, while of the 61½ shipped hence for Britain

* Total to all America 865,000 lb.

only about 60 are likely to reach it before the close of the year, the proportions in which our teas are likely to be taken by Britain and other countries in 1891 will be about as follows:—

Britain	58,000,000 lb.
Other countries	6,000,000 ,,
Total	64,000,000 lb.

Of the whole of our crop, Britain and British Colonies, Australia (Canada, India, Mauritius, &c.) take about 62,500,000 lb., against 1,500,000 taken by all foreign countries,—whether direct from Ceylon or by way of Britain!

Such figures strongly emphasize the necessity of abating no effort to open up and cultivate markets for our tea in countries beyond the bounds of the British Empire.

The United States, instead of less than 500,000 lb. of our tea, ought, before the close of this century to be our customer for at least 30 millions; Russia instead of a beggarly 53,000 lb., taking at least 10 millions, and Canada an equal quantity. Germany and Holland should not be far behind, while even France ought to take 5 millions instead of a miserable 65,000. There are great possibilities too in the expansion of the Asiatic markets, if only peace and progress can be preserved. But "Push! push! push!" must still be the motto of Ceylon tea planters.

THE REPORT OF THE LANKA PLANTATIONS COMPANY (LIMITED).

The annual statement published by the directors of the above Company has always a particular interest. It is one of those Associations, now but comparatively few in number, which have had to fight the battle of the changed conditions which some years back overtook this colony, and which yet continue the cultivation on any considerable scale of that product which, after giving to this colony a cycle of years of great prosperity, failed so suddenly and almost so utterly. Coffee still finds mention, and in no insignificant degree, among the sources whence the Lanka Company derives its income, and on that account, as well as from the fact that the report under notice evidences that the Company is emerging from its long season of difficulty, that document will be regarded as one claiming particular attention by ourselves and by our readers. No less a sum than £9,603 18s 9d was obtained for the coffee produced during last year on the Company's estates, the weight of the crop being 2,031 cwt., or approximating to something like 100s per cwt. This crop appears to have been a satisfactory one on five of the estates growing coffee, and we must presume that on other of the Company's properties the yield had not been so good. It would seem that the directors were determined that nothing should be left undone to maintain a high cultivation of such fields of coffee as continue to promise well, while they had decided to gradually substitute tea in those localities where the trees did not give evidence of a lasting vitality. It would be interesting to know how it can be that a tree, which at one time flourished under almost all conditions in our hill country, now promises vitality only in certain restricted areas. Might not consideration given to the conditions under which it still survives enable some conclusions to be arrived at as to how such conditions might be secured for other localities? Or is it simply a question of shelter and of soil, or, possibly, one of the date at which

the still successfully cultivated trees were put in? The report furnishes us with no data by which such hypotheses as these could be replied to. It is, however, very certain that there yet remain to us fields of coffee which, at the present high rate obtainable for the berry at home, are very remunerative. And yet, in the face of this fact, the directors of the Lanka Company announce that "each year the acreage becomes unavoidably smaller." It is a pleasing feature of the report that it informs us of a sufficiently profitable result to the year's working to enable substantial dividends to be declared. Even with an unfavourable rate of exchange during the first half of the year, the profits made reached £6,443 2s. 6d. From this the directors have decided to pay 6 per cent on the preference shares, and, but for precautionary reasons, they might have declared 4 per cent on the ordinary shares. We are not saying that these are high rates of dividend, but they at least show a very marked advance as compared with many past years. Reverting to the matter of produce on the Company's estates, it is to be observed that cinchona is still regarded as almost a hopeless production, and so we must consider it to be until "time brings about its revenges." On the other hand, cacao appears to have given such good results that the directors are anxious for more capital to develop its cultivation, and the Company appears to have been fortunate in discovering upon its properties sites well-suited to its somewhat capricious taste. We note that 341 acres planted with cacao returned last year a profit not far short of £3,000. This seems good enough to tempt further extension, and will doubtless set some of our planters on a further look-out for such localities of soil &c. on their estates that might prove suitable for experimenting. We notice that the average price obtained for the Company's tea throughout last year was 9½ p. per lb. net.

CONSUMPTION OF CEYLON TEA IN BRITAIN AND HER COLONIES AND IN FOREIGN COUNTRIES.

By an unaccountable oversight, we yesterday, in dealing with the comparative consumption of Ceylon teas in Britain and her colonies and in Foreign countries, omitted to include Australia in the former category while the figures against it went into the latter. The result was to give a far too favourable idea of the extent to which, with all our efforts, we have been able to open markets for our teas other than those of Britain and her colonies. The real figures are such as will still more enforce the necessity and the duty of relaxing no efforts to open foreign markets, especially those of the American continent by means of the Chicago Exhibition. Supposing Ceylon produces, as we estimated, 65½ millions of pounds of tea in 1891, we may, perhaps, strike off the odd half million for local consumption. The disposal of the rest will then be:—

Taken by Great Britain, say	60,000,000
" British Colonies, "	4,500,000
" Foreign countries (only)	1,500,000

So that, allowing for portions of the exports to India and China (Hongkong) going ultimately to foreign countries, the proportion of our crop of 65½ millions (with the prospect of considerable increase for half a dozen years to come) taken by foreign countries is considerably less than two millions of pounds! We confess to being personally taken by surprise by such a result as this. Our planters and their agents have made no impression worth mention on Russia

and as yet there is nothing very hopeful in regard to the other great tea-consuming country, the United States. This is not a time for holding back on any pretext, but for a long pull and a strong pull and a pull altogether in favour of the introduction of our teas into foreign countries, especially the United States, Russia, Germany and France.

THE TEA ROLLER PATENT CASE.

The case for infringement of patent at the instance of Mr. Wm. Jackson against Mr. A. Brown and the Commercial Company came before Mr. Morgan in the District Court of Colombo yesterday afternoon.

Mr. WITHERS for the plaintiff wished to know whether any legal objections were going to be pressed; and being told by Mr. Browne that there were he said they should be stated so that he might be able to meet them.

Mr. BROWNE for the defendants said it would be a good thing if they could get the issues in law and fact laid down in the first place. He suggested that members of the bar might make it a point of practice amongst themselves that plaintiff's counsel should draft the issues and submit them to defendant's counsel say a week before the trial came on. If they were accepted and good, but if the parties disagreed then the Court would have to settle them on the day of the trial.

The JUDGE said it would be a very convenient way of doing business.

Mr. WITHERS wished to know the legal issues. The only one, as he understood, was that remedy by this action was barred, because the plaintiff had not taken a statutable remedy.

The JUDGE said these appeared to be two matters of law. It was stated that the plaintiff had not stated the invention in respect of which exclusive privilege was granted to him, and secondly it was stated that the plaintiff should have recourse to certain procedure.

Mr. WITHERS remarked that the defendants in their answer did not say that the machine referred to was the one of which the plaintiff complained.

The JUDGE thought that was the inference from the whole of the answer.

Mr. BROWNE said the argument on that part had better be postponed till it was shown, so far as the plaintiff's case had gone, that it was the triple action tea roller which was the machine that he complained the defendants had imported and sold in Ceylon. If he said that it was, which the pleadings did not as yet disclose, it might be time for them to say "Oh! we have taken a patent for that." It was a matter that would arise out of the state of facts that might be proved.

Mr. WITHERS thought that had better be assumed for the sake of argument.

The JUDGE was understood to say that he thought there could be no doubt that it was the triple action machine that was referred to.

Mr. BROWNE said the plaintiff in the fourth paragraph of his libel did not say that the machine which the defendants had imported was the triple action roller. He only said they had infringed the plaintiff's patent right by importing into and selling in Ceylon machinery and apparatus for rolling tea possessing the arrangement described in the specification of the plaintiff's patent. The second objection was a special defence in law which might arise hereafter according to the facts, but he intended to press the objection that the plaintiff had not disclosed any cause of action against them. The plaintiff had not alleged what was the invention in respect of which exclusive privilege was granted to him. The whole machine was described in the specification. Had the defendants infringed the whole of it? Three things were singled out afterwards, but the plaintiff did not particularise what was the invention infringed. He did not say that it was the arrangement for transmitting motion to the top rolling surface through the case or jacket surrounding it. Mr. Browne then proceeded

to refer the Court to the case of Foxwell v. Bostock in Goodeve's patent cases. Reading through the specifications he said there were really four inventions, the whole thing and three parts. Which of the four were, the defendants going to take as the invention upon which the plaintiff proceeded in this claim.

The JUDGE said it seemed to him that plaintiff complained that what had been infringed was the arrangement described in the specification as the arrangement for transmitting motion to the top rolling surface through the case or jacket surrounding it which was a substitutive part of his invention.

Mr. BROWNE:—Is that the only claim?

The JUDGE:—I understand so.

Mr. BROWNE:—Then let him bound to that.

Mr. WITHERS:—So were.

Mr. BROWNE asked the Court to note his objection that in the specification the plaintiff practically claimed a patent for four things.

Mr. WITHERS afterwards referred the Court to a decision by Lord Justice James, one of the best judges that ever lived, and also pointed out that under section 21 of our Patents Ordinance no suit should be defended on the ground of any defect or insufficient specification of invention upon the ground of misdescription of the invention in the petition unless the defendant shall show that he is the actual inventor. He subsequently stated the issues as follows—(1) What is the nature of invention the plaintiff averred the defendants have infringed; (2) was the plaintiff the first and true inventor of that; (3) was it new and useful and had the defendants infringed it?

Mr. BROWNE intimated his acceptance of those issues and thereafter the Court adjourned for half-an-hour or tiffin. On the Courts resuming,

Mr. WITHERS opened the case for the plaintiff. He thought he need hardly dwell upon the policy of the patent law which affected all its subjects who invented manufactures which were useful to the subjects. In the science of economics a man's good name, skill and industry were as much his property as a man's house or garden or his balance at the bank and as deserving of protection as other kinds of property. The law had a special regard for a man like Mr. Jackson who was the pioneer of a very useful invention in a country like Ceylon. Mr. Jackson was an engineer by profession. He went to India early in the seventies where for two years he studied tea as a product, and from that time till now his whole time and labour had been devoted to the contriving of machines useful in manufacture of tea. The particular kind of machine to which he had given time and attention and to which they confined themselves in this case, was that for rolling tea and producing that particular curl or twist in the leaf which gave it a marketable value. They must first consider what a manufacture was. In our Ordinance an inventor "shall include the inventor and an invention not publicly known or used in Ceylon," and it would simplify matters very much if the court would bear in mind that from first to last in this case they were confined to inventions in Ceylon. The plaintiff's was an improvement on machines for rolling tea, not machines all over the world, although he thought the Court would be satisfied after hearing the case that it was a distinct improvement on any machine that was ever made for the special purpose, but an improvement on pre-existing machines of this class in Ceylon. The word invention included "an improvement"—and the machine in question was an improvement—and the word manufacture included "any art, process or manner of producing, preparing or making an article, and also any article prepared or produced by manufacture." In Johnston's pages 16 to 19 the word had a larger signification and included in its terms the part of the plaintiff's claim which had been so often cited. At the time Mr. Jackson invented the machine in question which is called the "Excelsior" or the "Universal"—sometimes both names were used but they merely devoted a difference in size, the "Universal" being a larger machine than the "Excelsior" but the same in principle—it would be proved that in Ceylon there was no other machine of this class in

perfect use or really had ever been in perfect use except one which Jackson had himself introduced into Ceylon some few years before which was called the "Standard," and for which he had taken out a patent in India. He had not taken out a patent in Ceylon, but the machine came to be used in Ceylon and it was the only one that had existed in Ceylon before and at the time Mr. Jackson invented his "Excelsior" which was an improvement of the "Standard." The learned gentlemen then proceeded to describe the "Standard," the "Excelsior" and Brown's triple action tea roller of which he had models before him. On his left was the machine which the plaintiff complained of as infringing his manufacture, that was his improved arrangement for the transmission of motion through the case or jacket surrounding it. On his right was the "Standard," and in the centre the "Excelsior." The "Standard" might be roughly described as a machine for tea rolling between surfaces called tables. The lower table was that on which the tea was placed, and it was between it and the upper table or surface that the tea was rolled. Of course the tea had to be confined in some way so that it should not escape all over the machine. In the "Standard" the tea was confined in a loose case or jacket, a sort of box. Inside this case was the upper table or cap which pressed the tea down on the lower table, there being weights upon it or other machinery for giving pressure. In the "Standard" the cap when it was moved by the machinery attached to it carried the jacket with it. Now the ordinal difference between the two machines was that in the "Standard" the driving machinery was attached direct to the upper table and carried the jacket about with it, and in the other it was exclusively attached to the cap and had nothing whatever to do with the jacket. There were several defects in this machine. One was that the loose case or jacket actually rested on the lower table and when it was carried about by the cap to which the driving machinery was attached it of course rubbed the lower table and the wear and tear was very considerable. Not only did it tend to destroy the machine itself but it interfered very much with free movement of the machinery making it very stiff in action. Another defect was that the cap or upper table had no movement upwards; one could not see what was going on with the tea; and one could not feed the tea except by pouring it down through the cap itself. This was very inconvenient and in order to obviate that Mr. Jackson happened to think of a plan by which he could drive the cap about the lower surface and yet leave the cap itself free to move up and down. That was one of the very useful advantages derived from this improvement. Now really the improvement in the "Excelsior" over the "Standard" was that it was the jacket itself which carried this about and caused the eccentric motion so that at the same time while it was in motion this could be lifted up or down and fed through what was called the hopper and through which one could see what was going on with the tea underneath. Simple as it might seem great ingenuity was required to do that. If he had left the jacket as it was resting on the table it would have torn the whole lower table to pieces; it tore it about sufficiently when it was going about loosely with the cap; and so he had to devise a means of suspending the jacket on suitable bearings, just not quite touching the lower table so that it might go rolling and rolling about without coming into actual contact with the lower table without of course letting the tea escape without wear and tear of the table, and without the stiffness of movement that the older machine had and so as to allow the cap to be lifted up and down—it had an automatic movement—and so as to be able to feed the machine and see what was going on. The contrivance of attaching the machinery to the table itself and carrying about the cap had been transformed into the very opposite process of attaching the machinery to the jacket and driving the upper table in it—exactly the converse motion—and it required a good deal of ingenuity to bring that about. That really was the improvement of the one machine upon the other. With regard to the machine on his left he must read

the specification and explain how the parts of it corresponded with the parts of his machine.

Mr. BROWNE:—Does my friend propose to read the specification in evidence.

Mr. WITNESS:—Yes.

Mr. BROWNE then objected on the ground that what the defendants were charged with in this case was importing and selling and in the case of the second defendant company using certain machines an alleged infringement on the plaintiff's machine. They were not charged with having patented a machine or made a specification and thereby infringed a right. In other words they were charged with things they had done and not with things they had written or said the specification might possibly affect whatever assigned or filed it. It could no more affect anybody else in this suit than it could affect any leading merchant in the Fort like Mr. Henry Bois for instance, and therefore it was inadmissible in evidence as a second ground against anybody except the person who signed it.

The JUDGE was understood to say that being part of the defendants' answer the plaintiff had a right to refer to it.

Mr. BROWNE:—Possibly as a matter of pleading but not in evidence.

Mr. WITNESS then proceeded to identify the various parts of the one machine with the other. The difference struck the eye at once. There was nothing of the kind ever seen before in any machine in Ceylon or, he made bold to say, in any tea roller elsewhere, and its usefulness would be proved by the fact that it had met with public acceptance. Hundreds of the machine had been sold, and that was one of the ordinary proofs of usefulness. It was most useful by having the independent vertical movement by which it could be fed easily; and by having the parts removed which required oiling so that not a drop could fall into the tea. He would read from the specification to show the corresponding parts of the other machine. It was said that the invention consisted of a circular table or of platform and hollow cylinder in which the latter revolved a circular lid. That circular table or platform answered to the square table of Mr. Jackson's machine and theirs was round whereas Mr. Jackson's was more or less square, the square hollow cylinder answered to the square hollow jacket in which the latter revolved, and the circular lid was the upper table corresponding to the square cap in the "Excelsior"; and it was perfectly clear that the motion which was directly imparted was an infringement of the motion in Jackson's machine. It was also said that they imparted eccentric motion to the table, that was the bottom one, and to the whole cylinder. That showed that the driving machinery in Brown's imparted the motion the same as in Jackson's. It was also said that the cylinder carried the table with it and that was really a description of plaintiff's machinery, the only difference being in shape; that what Mr. Jackson had done on the square they had done in the round. In reply to the Judge he showed that the triple action was fed in the same way as the "Excelsior." In conclusion he said that however much the alleged infringing machine might differ in appearance from Mr. Jackson's the court must not be guided or influenced by that. Parts of Mr. Jackson's machine might be omitted in the infringing machine; there might be additions to the infringing machine which were not in the plaintiff's; these omissions or additions might make the defendants' machine a better one than his; but all that went for nothing if the plaintiff's vital arrangement had been substantially taken and by them and with all these omissions and additions the machine was a colourable imitation of the plaintiff's patent. (Mr. DORNHORST:—I admit that to be the law.) He cited the case of Proctor v. Bennis and called upon the plaintiff to give his evidence.

Mr. Wm. JACKSON, the plaintiff, examined by Mr. Withers said:—I am a mechanical engineer by profession. I began the study of my profession when I was 16 years of age and served an apprenticeship of 5 years. After that I went to India, going to Cal-

cutta and afterwards to Assam, where I was on a tea plantation of the Scottish Assam Co. for two years, after that I confined myself entirely to tea machinery—rolling, drying and sifting and various classes of machine. I came to Ceylon about three years after the introduction of this machine (the "Excelsior") I think. My first visit to Ceylon was during 1885 or 1886. I called at Colombo before that but did not stay. I first introduced some of my machinery here in 1878 or 1879 when the "Standard" machine which was sold in London was sent out. As far as I am aware that was the machine in use up to the time of taking out the "Excelsior" for which I took out a patent in April 1881. The "Standard" was one of my inventions. It was invented when I was in India. The first thing that led me to invent the "Excelsior" was that the planters wanted a less costly machine, and in the "Standard" there was a considerable amount of time wasted in India where the leaf was rolled very much quicker than here in trying to get the leaf down through the centre of the roller cap. The next point was that the jacket had to be made heavy to prevent it from jerking or jarring over the leaf whilst it was contained by it. The jacket of the "Standard" rests on the lower table and its heavy weight made it stiff to drive. I was not satisfied with the rolling obtained by that machine, and what I had in my mind when working out the idea of the "Excelsior" was to contrive that there should be the same action on the leaf as in the case of the Standard, but in a less costly way and that the machine should be more easily driven and worked. In the "Excelsior" it is necessary to place the leaf on the feeding platform at the top of the machine. If you place a sheet of paper on the lower table and pass a pencil through the upper surface, jacket or cap a true circle will be described. That motion is precisely the same as the motion of the "Standard" when the cranks are geared up at right angles to each other. I have now transferred the driving mechanism from the cap or upper rolling surface to the jacket surrounding it, that is to say that I have connected the driving crank with the jacket itself. The driving mechanism in the "Standard" was coupled direct to the upper rolling surface or cap, the jacket surrounding such upper cap or surface being left free or loose. In the "Excelsior" or improved machine I have just reversed that. I have taken the driving mechanism away from the upper cap or surface and attached it to the jacket which surrounds the surface. By connecting the driving mechanism to the jacket I was enabled to keep the lower edge of the jacket or outer case just clear of the lower table. By this arrangement of driving through the case or jacket I was also enabled to secure free vertical movement of the surface. In connection with that I was the first to introduce the bow and bracket attached direct to the jacket through which the cap is operated. This arrangement of driving through the jacket which we must continue to refer to as the jacket enabled me to lift the cap sufficiently far to feed the leaf in on one side underneath. I can see the leaf being operated on in this machine by looking through the same passage as the leaf is passed in. That passage is called the hopper. The pressure by the cap on the leaf under this system resulted in the work being accomplished more quickly and promptly than under the old system in the "Standard." By transposing the driving mechanism from the cap to the jacket surrounding it, the dirty, greasy oily parts are removed from the cap or top of the surface. In answer to Mr. Morgan he said:—The jacket in the "Standard" weighed from one to two cwt. and that weight resting on the lower table whilst the machine was in action produced an amount of wear and tear on the lower table which wore that lower table out. That wear and tear does not take place in the other machine because the weight does not rest on it. Replying to Mr. Withers he said:—Of the "Excelsior" embodying the improvement of driving through the jacket we have sold I suppose 800 in Ceylon. Did the "Excelsior" that you brought out when it

became known to the public in Ceylon supplant the "Standard." Yes. We did not sell any more "Standards" when this became known. There was really only one "Standard" sold in England for Ceylon. We never had any enquiries for the "Standard" when the "Excelsior" became known. Ever since I took out this patent I have had the exclusive use of the invention. In 1885 I considered that my privilege was interfered with by Mr. Kerr against whom I brought an action for infringing my patent in Ceylon and I succeeded in so far as after that action he never interfered with my patent. Since that it has not been interfered with to any great extent. The defendants' machine is known as Brown's triple action roller, and I have seen that machine in action on Bearwell estate in Lindula, on Heufold in Dikoya, and on the Great Western estate. I produce the model, I swear that the model before me is a substantially faithful copy of the "Standard." The difference between the model which I produce of the "Excelsior" and that which the defendants produce is that in the latter the spindle is plain and in the former the spindle is screw cut. In the model produced by the defendants also the bow is fastened to that outer casting, which is according to the specification of patent, and in my model here it is fastened to the web of the jacket. Will you explain where the triple action roller infringes your arrangement of transmitting motion to the cap through the surrounding jacket? Will you explain to the Judge in what respect the defendants' machine complained of infringes the "Excelsior"? In respect that the driving mechanism is coupled to the jacket direct. It is on that point that I complain. The results flowing from that arrangement are the same in the defendants' machine as in the "Excelsior." There is free vertical movement of the cap as in the "Excelsior," the only difference being that the manipulation is by a lever instead of a screw and nut as in my model and in actual practice. In the specification it is worked by a pulley and chain for which I have substituted the mechanical equivalent of a screw and nut. Another result of adopting my arrangement is that one is able to feed the tea underneath in the triple action roller just as in my machine; also the lower edge of the jacket comes down to the lower table but does not rest on it. The carriage of the jacket is just free of the lower table. These results flow from entirely from my arrangement. Without that arrangement they cannot be produced; the production of these results required the invention of that arrangement. If you pass a pencil through the jacket of the triple action roller and place a sheet of paper on the lower table a true circle will be produced just as in my machine. I produce in evidence a certified copy of the letters patent, a certified copy of the specification.

This concluded the evidence; and as was mentioned yesterday the further hearing of the case was adjourned till 28th January. Mr. Browne stated that his cross-examination of Mr. Jackson might last about three hours and Mr. Withers said that he had three or four scientific witnesses and formal evidence that the machine was used. Mr. Browne laughingly remarked that this was a case that was going to the Privy Council in the end.

(To be continued.)

BOTANY OF THE EMIN RELIEF EXPEDITION.

The botanical exploration of Tropical Africa leaves so much to desire that it was somewhat disappointing to find that Mr. Stanley brought nothing back which would give any idea of the nature of the dense forests which he traversed. The conditions under which such an expedition is necessarily executed make natural-history collecting extremely difficult. Travellers, however, often suppose that because they cannot make extensive collections they can do nothing to add to our knowledge. Yet to fill a small portfolio with well-selected and significant specimens is not a very difficult matter, and these may often furnish the basis of useful and important conclusions as to the

general nature of the flora. Sir Joseph Hooker was able to give the first account of the vegetation of Kilimanjaro from a small parcel of plants collected by a missionary, the Rev. Mr. New, who was supplied for the purpose by Sir John Kirk, with "a bundle of old *Guardians*." An officer of the Ashanti Expedition brought from Comassi the fruit of what proved to be a new species of *Duboscia*. And quite lately Lord Lamington sent to Kew a small parcel of plants collected by himself in an expedition through the Shau States, which contained good specimens of an interesting plant only known previously from imperfect material collected by Griffith. It has now been worked out and figured in the Kew "*Icones Plantarum*."

Nor is it so difficult as it might be supposed to do even more than this. And I am not sure that a little careful and intelligent plant-collecting would not be a healthy and useful distraction to the tedium and strain of an arduous journey. Nothing could probably exceed the difficulties under which Joseph Thomson travelled in Massailand; yet he managed, notwithstanding, to get together a tolerably extensive and most valuable herbarial collection. Upon this Sir Joseph Hooker was able to base the first attempt at a rational theory of the geographical relations of the high-level flora of Eastern Equatorial Africa. Nothing, again, could be more admirable than the collections made by Brigade-Surgeon Aitchison when attached to the Kuram Field Force under Sir Frederick Roberts in Afghanistan. And the Government of India has now arranged—and it is an indication of the sympathy for science which animates its members—that, as part of the organization of the Botanical Survey of India, a botanist shall for the future be attached to all frontier expeditions.

Major Jephson,* who accompanied Mr. Stanley, seems, however, to have had his eyes shut him. A correspondent has sent me a copy of the October number of the *Mayflower*, a small monthly horticultural periodical published in New York, which contains (pp. 155, 156) a short paper by him on the "Plants of the Dark African Wilderness." This seems to me worth putting on record in the pages of *Nature*, where it will be at least more accessible for future reference. At my request, Mr. Baker, the Keeper of the New Herbarium, has had the paper annotated with such critical comments as were possible.

To Major Jephson's paper Mr. Stanley has prefixed a brief introduction, which adds nothing of importance. He remarks:—

"In this branch of science I fancy we were all but amateurs, and considering what very little time any of us could devote from the engrossing business of marching, and seeking for food to sustain life, Mr. Jephson shows what might have been done by him had circumstances been more favourable."

This is, however, erring a little on the side of modesty. As I have already shown, amateurs can do very useful work without much difficulty, if they are content to do only a little, but to do that little carefully. Some further observations are open to more serious criticism:—

"Africa is yet too young and too crude for the scientific botanist. We have only been pioneers to stake the highway to make ready for those who shall come after us. When the rails have been laid in pairs of iron lines across the swamp and desert, and the engined boat cleaves the red bosoms of the great rivers, and furrows the dead green face of the fresh-water seas, then the tender-nurtured botanist, conveyed from point to point without danger to his valuable life, may be trusted, with his enthusiasm and devotion, to bring to us results worthy of science and the age. Of those who have given us an insight into the botanic treasures of the African world, Schimper (sic) is by far the best; but he has also laboured under such disadvantages and discomforts that he was not able to do for Equatorial Africa a tenth part of what Bates did for the Amazon."

* Mr. Jephson is not a military man: he was a Ceylon planter not long ago.—Ed. T, 4.

One cannot but wonder a little at the ignorance of the literature of African travel which this paragraph displays. Men like Grant, Speke, Kirk, Welwitsch, Mann, Vogel, Bartter and Thomson to mention only a few of those to whom we owe our knowledge of the African flora, would have thought it comical to be described as "tender-nurtured" botanists. The work of Schweinfurth was admirable; yet no one would, I think, be more surprised than that distinguished naturalist, Mr. Bates, to learn that the botanical collections which he never even professed to make, were ten times better.

Royal Gardens, Kew.

W. T. THISLTON-DYER.

"It is difficult to give an accurate idea of the flowers we saw on our march through Africa in a short magazine article, but I here give a short sketch, mentioning some few things which I think may be interesting to my reader.

"The great forest of Central Africa through which we passed is not so rich in variety of flowers and orchids as the forests of Mexico and Brazil, or even the jungles of India and Ceylon. It is chiefly rich in flowering vines, trees, lilies (a) and *Bigonias*. There is, however, a great wealth of different kinds of ferns, such as I have often seen cultivated in hot-houses in England. In many places the damp ground was covered by a thick growth of filmy ferns and *Lycopodium* of the most beautiful description.

"Here is a short extract from my journal which will give some idea of the everyday-sights we saw on the banks of the Lower Cougo, 1,700 feet above the sea and 250 miles distant from it:—

"At the bottom of a piece of swampy ground I came to a small stream, on the banks of which were growing *Osmunda regalis* (b), or Royal fern. It was slightly stunted in growth, being not more than 2 feet in height. It is the first I ever have yet seen in the tropics. Close by the stream was growing a group of beautiful ground orchids (c), in form like a *Hyacinthus candidus*. There were clusters of great pink flowers with yellow centres; the whole had a very gorgeous effect. Here, also, was a profusion of *Lycopodium* (d). It is of a kind I have not yet seen; it creeps up and over everything in great bluish-green masses; its long tendrils creep up the tree trunks like ivy, to a height, in some cases, of 4 feet. There were quantities, also, of the ribbon fern, exactly like the *Davallia pentaphylla*, (e) which has been introduced into English hot-houses from the Malayan Archipelago. What would not florists at home have given for an acre of this ground?"

"In the forest there were two kinds of lilies which were common. One, which grew in swampy ground, was in form like an *Amaryllis*. (f) It was white, with a deep crimson centre, and had a delicious but heavy scent. The other was a lily, (g) which grew everywhere through the whole length of the forest. It was of a brilliant scarlet colour, and was formed of several hundreds of small flowers, forming a round ball like a huge Guelder rose, four inches in diameter. It was of such a brilliant scarlet that it looked almost metallic, growing in the darkest recesses of the forest. One of the commonest and most striking of all the ferns we saw was the *Platyserium alicorne*. (h) It is an extremely interesting fern, one of a singular genus of epiphytal plants, growing on the branches of trees. Our Zanzibaris called it 'elephant ear,' from its curious shape. There was another of the same

family, *Platyserium Stemmaria*, which we found growing upon rocks in the open country. Both these ferns grow at altitudes from 1,000 to 5,000 feet. Tree-ferns (i) of the ordinary kind we found growing in all the gullies and streams on the slopes of the mountains above the Albert Nyanza. The altitude was from 5,000 to 6,000 feet above the level of the sea, and I noticed especially that the flora here was remarkably like that in the Central Province of Ceylon, which is an altitude of 2,500 to 4,000 feet above the sea.

"By far the most common plant which we saw in the jungle was the Amomum, or wild cardamom. (j) It was almost precisely the same in form as the cardamom which is cultivated in Ceylon. It grew almost throughout the whole of Central Africa. It has a large purple flower, which grows in clusters on the ground at the root of the plant, and from it a bright scarlet fruit forms, of a pear shape, and about the size of a small fig: It is divided into four quarters, and contains some white, fleshy pulp, very juicy and acid. This pulp is of small black aromatic tasting seeds like those of the cultivated cardamom. If ever planters go into Africa, the cardamom will be an important product of the soil for commerce, for there are vast tracts of forest with the climate, soil and cheerer shade which are necessary for the cultivation of the cardamom. Orchilla weed should also become a valuable article of commerce; it grows in many parts of the forest. I consider, however, that when the great forest of Central Africa is opened up to civilization, by far the most valuable article of commerce will be india-rubber, the want of which is increasingly felt in the civilized world. Now that electricity is so much used for various purposes, the demand for india-rubber grows larger and larger: the supply which is shut up in the African forest is practically unlimited. There are various trees of the fig tribe which yield this product, but by far the greatest amount is contained in the india-rubber vines (k) which abound in the forest and hang from almost every tree. In cutting our way through the forest in some places, we got covered with the milky glutinous sap, which dropped upon us from the vines we cut through.

"The natives know its value, and use it largely for smearing the inside of their huckets in order to make them hold water. They use it largely also for covering the ends of their drumsticks. The india-rubber obtained is of a clear, yellowish colour, like glue, and is of the most elastic description.

"In the forest region I saw no water lilies, but in Emin Pasha's Province in the Bari country, I saw two kinds. (l) They were both about the size of an ordinary white water-lily, and the leaves and flowers floated on the surface of the water, but the stalks and formation of the leaves and flowers was finer and more slender. One was of a pink coral-like colour, not white like the Zanzibar lily, and the other of a pale bluish lavender. They were growing in small clear pools only a few miles apart in the valley of the Nile, at an altitude of about 3,000 feet above the sea.

"One of the most interesting botanical discoveries I made in the forest was the discovery of a wild orange tree. During our march through the forest I had continually come upon trees varying from 8 to 15 feet high. They had double leaves of a peculiar shape, which had a delicious smell like orange leaves; the branches were covered with long sharp thorns, and I at once pronounced them to be orange trees. My fellow-officers smiled incredulously, and exclaimed: 'Orange-trees (m) in the middle of the forest!' But I held to my opinion, and

(a) *Crinum*.

(b) *Osmunda regalis* is cosmopolitan, but in tropical zoenia high up only.

(c) Mr. Rolfe cannot suggest anything better than *Liseochilus*.

(d) *Selaginella scandens*, no doubt.

(e) "Ribbon fern" would suggest *Ophioglossum pendulum* or *Vittaria*, but they are not like *Davallia pentaphylla*.

(f) *Crinum zeylanicum*.

(g) *Brunsvigia toxicaria*.

(h) *Platyserium alicorne* is not African, but *P. Stemmaria* is widely spread.

(i) No doubt *Cyathea Thomsoni*, Baker, which is very near *C. Dregoi* of the Cape.

(j) There are a large number of Amomums in West Tropical Africa. The fruits are 3- not 4-celled. See *A. Daniellii*, &c., in Oliver and Hsahury's paper in Journ. Linn. Soc., vii. 109.

(k) *Landolphia*.

(l) *Nymphaea stellata* and *N. Lotus* are both plentiful in Upper Nile-land.

(m) This reads like a tree *Citrus*, and if so is an interesting discovery, as no species is hitherto known here.

just before reaching the open country, I came upon a tree with both flowers and fruit upon it. The flowers were exactly the same as the flowers of a cultivated orange tree. The fruit, which was green, was about the size of a marble. On cutting through it with a knife I found it had the same divisions as an ordinary orange, but each division was full of small seeds, which were very bitter and aromatic. On reaching Emin's Province I told him about it, and he regretted very much that I had not brought a specimen with me, for he was a good botanist and wished to add it to his collection of dried plants. He told me my discovery was doubly interesting, as many years before a German had penetrated the forest on the west coast of Africa, and reported that he had found wild orange trees. His story was discredited, and now on discovering the orange tree in the forest pointed that his report was after all true.

"I have not space to speak much about the flowers we saw in the open country, but will say a few words about those flowers which we found at a high altitude on the slopes of Ruweozori, or the Mountains of the Moon. Lieutenant Stairs who made the ascent of the mountains, gives the following facts in his report:—

"The barometer stood at 21 10, thermometer 70° F. A number of us and rising in one envelope stood a peak, in a tale 1,200 feet higher than we were. This we now started to climb, and after going no a short distance came upon three heaths. Some of these must have been 20 feet high, and as we had to cut our way foot by foot through them our progress was necessarily slow. Here and there were patches of inferior bamboo, almost every stem having holes in it made by some boring insect, and quite destroying its usefulness. Under foot was a thick spongy carpet of wet moss, and the heaths on all sides of us we noticed were covered with 'Old Man's Beard' (*Usnea*). We found great numbers of blue violets which had no smell, and from this spot I brought away some specimens of plants for Emin Pasha to classify. The altitude was 8,500 feet. We found blueberries and blackberries (*n*) at an altitude of 10,000 feet. The following (*o*) are the generic names of the plants collected as named by Emin Pasha:—

- | | |
|------------------------|--------------------------|
| Olemtia. | Moschozma. |
| Viola. | Lisochilus. |
| Hibiscus. | Luzula. |
| Impatiens. | Carex. |
| Tephrosia. | Anthistiria. |
| Glycine. | Adiantum. |
| Rubus. | Pellaea. |
| Vaccinium. | <i>Pteris aquilina</i> . |
| Begonia. | Asplenium. |
| Peuce lanum. | Aspidium. |
| Gnaphalium. | Polypodium. |
| Helichrysum. | Lycopodium. |
| Senecio. | Selaginella. |
| Sonchus. | Marobantia. |
| <i>Erica arborea</i> . | Farmelia. |
| Landolphia. | Dracena. |
| Holiotropium. | Usnea. |
| Lantana. | Tree Fern. |

"These were just a few specimens Lieutenant Stairs brought down with him. But the slopes of Ruweozori will, when properly explored, yield numbers of unknown treasures to be added to the Botanical Encyclopedia.

"For many weeks we drank coffee which we made

(n) It would be very interesting to have these identified. The two highest-known species of *Rubus* are *pinnatus* and *rigidus*, at 5,000-6,000 feet.

(o) This list is in Stanley's book. The *Viola* is no doubt *abyssinica*, common to the mountains of Madagascar, Abyssinia, the Cameroons, and Fernando Po. There are three heaths known on the high mountains of Central Africa, viz *Erica arborea*, *Ericiella Manii*, and *Blasria spicata*. There is no *Vaccinium* known before in Tropical Africa; though three or four are plentiful in Madagascar, and there is one on the Drakensberg, so that its occurrence is most probable. The ferns of Tropical Africa are nearly all species widely spread in other continents.

from the berries of the wild coffee-trees which abound on the highlands round the great lakes of Central Africa. The Arabian coffee was originally supposed to have come from Kaffa, in Abyssinia. That which we found in Karagwe; Ankori, and Uganda is equal in flavour to the finest Arabian coffee, and will, when Central Africa is opened up, be another of the chief articles of commerce.

"I. A. M. JEPHSON."

—*Nature*, Nov. 5th.

TEA AND COFFEE FOR FAT PERSONS.

We have received from Messrs. Chatto & Windus of London a copy of the third edition of "Food for the Fat: A Treatise of Corpulence, and its Scientific Dietary Cure," by Mr. N. E. Yorke-Davies, L.R.C.P., M.A.C.S., &c. The fact that this work is in its third edition within the course of a couple of years is a proof of its usefulness and acceptability among those troubled with obesity. It is written in a popular style, and gives valuable information as to diet, dress, exercise, &c., for those who wish to reduce their weight without injury to their health. The second part contains a large number of menus,—soups, fish, meats, vegetables, fruits, jollies, beverages and sauces. The author is a strong advocate of Ceylon tea. We quote what he says regarding tea and coffee:—

TEA: ITS USE.

Tea is not food, and should not be taken as such. Tea taken three or four hours after dinner is valuable, for this is the time that corresponds with the completion of digestion, when, the food having been conveyed away from the stomach, nothing remains but the acid juices employed in digestion. These acid juices create an uneasy sensation in the stomach, and a call is made for something to relieve this uneasiness. Tea fulfils this object better than stimulants; more than this, it satisfies some unknown want in the system. This refers to the moderate use and enjoyment of tea, but there is a large class who drink an enormous quantity of this beverage, to the undoubted impairment of their health.

Those who take it to excess are found principally among the poor.* They become pale and bloodless, much given to faintness, nervousness, and depression of spirits, and suffer excessively from flatulence and loss of appetite. This is no doubt partly due to poisons used to colour and adulterate it. One form of indigestion caused by tea deserves special notice, as it is commonly observed by medical men: the appetite is unimpaired, and no particularly unpleasant sensations are felt after meals; but almost as soon as food is taken it seems to pass out of the stomach into the bowels, causing flatulent, colicky pains, speedily followed by diarrhoea. Hence, there is a constant craving for food, and a feeling of sinking and prostration.

In moderate quantity, tea exerts a very decidedly stimulant and restorative action on the nervous system, which is aided by the warmth of the infusion, and is particularly useful in over-fatigued conditions of the system, and under these circumstances it is infinitely preferable to alcoholic drinks. Lord Welsley considers it is the best drink for exhausted soldiers after a long march.

The harmful effects of tea depend a great deal on the way it is made. If it is allowed to infuse too long the tannin and other injurious ingredients of even the best tea are drawn out and the infusion becomes bitter and astringent, and unpleasant to the taste. To make tea properly, the teapot should be warmed, and the water poured over the tea immediately it boils. Five teaspoonfuls of pure Ceylon tea should be put to each quart of boiling water, and it should draw for eight minutes. Professional tastesters are very particular to use only water which is freshly boiled.

* Whose sufferings, as described, may be due to want of nourishing food, mainly.—ED. T. A.

In China tea is sometimes infused in a teacup, and sometimes in the cup from which it is drunk. In Japan the tea-leaves are ground to powder, and, after infusion in a teacup, the mixture is beaten up until it becomes frothy, and then the whole is swallowed. The Chinese drink their tea in a pure state; the Russians take it with lemon-juice; and the Germans often flavour it with rum, cinnamon, or vanilla. In England we know it is customary to add cream, milk, or sugar, but for corpulent people the Russian mode would be the best.

Ceylon tea is now justly taking a high place in public favour. There is no doubt it is more wholesome and more delicately flavoured than any other, and as it contains more theine and less tannin than Indian and Obinee teas, is more healthy. It does not injure the most delicate stomachs, or disagree with those whose digestive powers are weak. When its virtues become fully known it will take the place of all other teas. It is a difficult matter to get pure Ceylon tea; most of those sold with high-sounding names as Ceylon tea are simply mixtures and blends in which common China tea predominates and the names of the estates they are supposed to come from exist only in the imagination of the dealer. One or two owners of Ceylon plantations do import their teas direct to the consumer; in this case it is a guarantee of their purity, and under these circumstances they can be bought much cheaper than where they have passed through the hands of the importer, the broker, and the tea-dealer.

Those who would like to have Ceylon tea in its pure and natural state can get it from the *Agra Ceylon Tea Association*, of 76, Shaftesbury Avenue, London, W. C., who import their teas direct from the estates in Ceylon of Mr. H. R. Farquharson, M. P., and it is handed to the consumer pure and unmixed as it leaves the factories.* Independently of its good quality and freedom from tannin, Ceylon tea is machine made and is not, like Chinese tea, handled and pressed in dirty and equal huts, and by the hands and feet of the unwashed Mongolian.

COFFEE: ITS USES.

'Coffee,' says Dr. Pavy, 'is said to have been in use in Abyssinia from time immemorial, and in Persia from A. D. 875. It was used in Constantinople about the middle of the sixteenth century, in spite of the violent opposition of the priests, and in 1554 two coffee houses were opened in that city. It was introduced into Europe in the seventeenth century. It was drunk in Venice soon after 1615, and brought into England and France about forty years after.' Like tea, coffee produces an invigorating and stimulant effect, without being followed by any depression, and fully justifies the estimation in which it is held. It increases the action of the pulse, and is more heating than tea, while at the same time it arouses the mental faculties and so disposes to wakefulness. To make the infusion properly 2 oz. of freely-ground coffee should be used to each pint of boiling water.

Coffee is especially useful to those who suffer from redundancy of fat, as it has the power of relieving the sensation of hunger and fatigue, and may be used two or three times a day as a beverage. It has all the advantages of a stimulant without the ill-effects following alcohol in its various forms. It exerts a marked sustaining influence under fatigue and privation, and sustains the strength where a restricted diet is necessary, and this enables arduous exertion to be better borne under the existence of abstinence or a deficiency of food.

THE OUTPUT OF BRITISH MINERALS.

There has recently been issued from the Home Office a tabular return, showing the annual output of the principal minerals produced in the United Kingdom, from the year 1860 to the year 1890.

* The writer's son is a pupil on this estate, and I gather these facts from him, and certainly can speak from experience of the delicious flavour of these teas. That sold at 2s per lb. is incomparable.

The term United Kingdom includes the Isle of Man and Ireland. The quantity in tons, and the value in pounds, are given for each year. The compilations have been made from Official Returns, by Mr. James B. Jordau, the clerk of Mineral Statistics. Copies of the return may be obtained from Messrs. Eyre and Spottiswoode. For the benefit of our readers, the figures for last year (1890) are culled from the report:—

MINERAL	QUANTITY Tons	VALUE £
Alum clay (Bauxite).....	11,527	5,763
Alum shale.....	6,420	802
Arsenic (white arsenic, crude and refined) produced from arsenical pyrites not included in the next line	7,270	60,727
Arsenical pyrites.....	5,111	4,414
Barytes.....	25,353	29,584
Clays (China clay, potters' clay, fullers' earth, &c., but exclusive of ordinary clays).....	3,906,214	899,166
Coal.....	181,614,288	74,953,997
Cobalt and nickel ore.....	81	260
Copper ore and copper precipitate:—		
Copper ore.....	12,130	27,801
Precipitate.....	345	4,670
Fluor spar.....	268	392
Gold ore (auriferous quartz).....	578	434
Gypsum.....	140,293	57,991
Iron ore.....	13,789,767	3,926,445
Iron pyrites.....	16,018	7,666
Lead ore.....	45,651	404,164
Manganese ore.....	12,414	6,733
Ochre and amber.....	19,068	17,475
Oil shale.....	2,212,250	608,369
Phosphate of lime.....	18,000	29,500
Salt (rock salt, and salt obtained from brine).....	2,146,849	1,100,914
Slates and slabs.....	434,352	1,027,235
Sulphate of strontium.....	10,276	5,138
Tin ore ("black tin").....	14,911	782,492
Wolfram.....	104	1,848
Zinc ore.....	22,011	109,890

It is to be noted that, in addition to the above, small quantities of other minerals are occasionally produced, e.g. ore of antimony and bismuth, bog iron ore (used for purifying gas), jet, lignite, petroleum, plumbago, silver ore, steatite and uranium ore.

"A very large quantity of stone used for building and other purposes is also annually raised, besides chalk, ordinary clay, gravel, &c., the total quantity of which cannot be accurately ascertained, but the value in 1890 was estimated to be upwards of £3,708,000."—*Chemical Trade Journal*.

CHINA TEA LOSERS.—We learn that the China Association has been asked to take up the consideration of China tea, in view of the heavy losses which have been made this year, and the great decline which continues unchecked. A meeting will be shortly called to consider the matter.—*L. and C. Nov. 27th.*

PERAK TEA.—The Manager of the Cicely and Hermitage Tea Estates, Mr. Fred. Watson, passed through Penang today with 2,000 pounds of tea for Singapore.—This is the first crop from these estates prepared by special machinery, the preparation of the leaf, formerly, having been done by hand.—*Straits Independent, 9th Dec.*

TEA-DRINKING IN JAPAN.—The *Athenaeum* in a review of Sir Edwin Arnold's new book "Seas and Lands" says:—

The author enlarges, too, on the institution of tea-drinking, a much more serious affair than the banquet, the strict etiquette and ceremonial recalling in a strange way the *kava* drinking of the Pacific Islands. The "cha-no-yn" (literally "tea of honour") is, indeed, not to be spoken of lightly, and the author describes with much gravity the proscribed treatment of the "honourable hot water," the reverent handling of the cup, and the refined conversation which alone is permissible during the function. It may, perhaps, be to Buddhism, as the author declares, that the Japanese owe not only the tea-leaf, but how "to honour, enjoy, and infuse it."

Correspondence.

To the Editor.

COFFEE CULTIVATION IN THE NEW
HEBRIDES.

Santo, New Hebrides, Oct. 30th.

SIR,—As many old coffee planters appear to be casting about for new soil and climate it might not be out of place to bring under their notice this island, which has upwards of 2,000 square miles of country, much of which is highly mineralized soil with any elevation up to 5,000 feet.

We have the same minerals as are found in New Caledonia, but no open country as on that island. The highest peaks here are completely overgrown with vegetation.

The timber is small and all soft wood. The banyan is the largest tree we have, and the remainder are acacia, wild fruits, and mostly the bastard cotton tree.

We have between 50 and 60 acres cleared, the cost of which has been from 25s to 30s per acre, that is with native labourers who work freely for payment, of which the standard is one stick of tobacco per hour. We have an average of 50 daily without intermission, but the number often reaches 160 and over; these are composed of different tribes who work in gangs. Of course no one would depend entirely upon native labour for any important work, but the facilities here for opening up the country and cutting roads by this means are worth consideration, as they thoroughly understand this part of the work and can work like demons at it for five or six hours. Any planter should bring a certain amount of labour with him, and with proper attention he can rely upon the natives for the bulk of the first year or two's hard work. The rainfall is considerable here; a drought of 10 days is an exceptional event, and if anyone speaks against this island or the climate, it is most likely to be the Fijians who would object to see it prosper. We have some acres of young Coffee Arabica 12 months old, but at a low elevation owing to there being no roads to the hills which are only three miles from us. We had 30,000 fine young seedlings from Ceylon, but on the recommendation of Mr. O. P. Atkinson, who was round here, we had them all completely destroyed for fear of the *hemiteia vastatrix* being introduced in the seed; those we have replaced with seed from Calcutta and other places known to be free from disease. Of course the drawback here just now is the want of some settled government, but this would follow immediately if any desire is shown by the planting community to make use of the land. At present the majority of settlers are composed of inexperienced English, French and Colonials (and the mission stations), all of which are likely to be ignored by the Home Government, but let a *bona fide* intending planter come here and state his wants and he is sure to receive attention.

We feel sure if some of your experienced planters saw this island and realized the position, compared with the interior of some countries where transport is difficult, they would never allow the French nation to have a say in the matter of annexation, and it is these northern islands that the French are most desirous of securing.

The object of the formation of the Australasian New Hebrides Company some two years since was, I believe, to encourage British settlement, as the French settlers were likely at that time to predomi-

nate. We have a monthly steam service with Sydney running in connection with the boats to and from Fiji, but more trade is wanted, and the islands are well worthy of more notice.—Yours faithfully,
POWELL BROS.

UNDULY NUMEROUS BREAKS OF TEA.

38, Mincing Lane, E. C. London, Nov. 13th.

SIR,—In the interests of all connected with the Ceylon Tea Industry we would call serious attention through your valuable columns, to what happened last Tuesday, when about 19,000 packages were catalogued for sale, and buyers had to taste nearly 800 samples! With the result that the auctions lasted from 12 o'clock till 5; and as the Trade were unable physically to value a large proportion of the teas offered competition was very dull and prices were unduly depressed.

We have frequently referred in our circulars to this vital question of the size of breaks—but the time has now come when something must be done or the industry will suffer; proposals are being made to render the Ceylon sales on Thursdays Independent of the Indian—an advisable change—but he shall be unable to combat this difficulty in the future unless we have the cordial co-operation of planters in reducing the number of samples by every means in their power.—Yours faithfully,

W. JAS. & HY. THOMPSON.

INFERIOR CEYLON TEAS.

13, Rood Lane, London, E. C., Nov. 20th.

DEAR SIR,—We forward you by tonight's mail samples of extremely common Ceylon tea. The prices realised by these teas ruled between 3d and 6d per lb. Some of the samples represent good sized breaks.

We have selected these to show you the poor quality of some teas now arriving from Ceylon, and we are sure that you will agree with us when we say that teas of this character are doing considerable harm to the Ceylon tea industry.

Ceylon tea has obtained a name in this country for good quality which is too valuable to be trifled with, and we would only ask that you will use your powerful influence in endeavouring to impress upon planters the necessity of not trifling with a name which is so good that many industries would be glad to possess it.—Yours faithfully,

GOW, WILSON & STANTON.

INADEQUATE SAMPLING OF TEA.

DEAR SIR,—Seeing your editorial on this subject in tonight's *Observer* (p. 449), I am reminded of the paper sent herewith, which has been lying on my table nearly a fortnight since it was written. With correct data the pencil figuring might be made interesting.—Yours
PLANTER.

THE PRICE AND SAMPLING OF TEA.

Is not the cause of low prices the utter confusion and disorganization of the London market? All the wholesale traders are able to snap up lot after lot of splendid tea at their own price, so that they by reason of the competition which this engenders—in order to make their turn-over large—constantly "bear" the market in order to sell cheap to the trade. The "trade" plays the same game with the consumers, so that tea of the best quality is (or should be) now everywhere procurable for a song, and the consumers will never care to give more. But what is at the root of all this evil? What, but the congestion in Mincing Lane. All the tea produced for

exportation in India, China, Ceylon and the world (the fraction sent elsewhere is not worth considering, unfortunately) has to be infused and tasted in a few rooms in Mincing Lane, by a small number of men who have been trained to do this. But they are completely overwhelmed by the rush of the sales, and thousands of lots must be left untasted and unpriced by the buyers, who, probably, to reduce their own risk, bid only a price at which they could not lose if the tea turned out to be of inferior quality. The producers therefore are the victims of this state of things in the central and sole outlet for our tea. What is the moral? Should America be won for our tea surely every pound of it consumed there should be shipped direct, otherwise we should be no better off than we are now. Centralization is sometimes good, but not when that centre is unprepared to do the work thrown upon it. Unfortunately the sole sufferers from this state of things are powerless to alter it. It makes no difference to the merchants and brokers, who, therefore, don't care.

TEA SALES IN MINCING LANE.

	lb.	lb.	
Ceylon	60,000,000	4,000 lots	equal to 15,000 lots.
India	100,000,000	do	do 25,000 do.
China	90,000,000	do	do 22,000 do.
Other	20,000,000	do	do 5,000 do.

290,000,000 Days sales 100 67,000 do.
Daily average 670 do.

Each in 5 grades, each sale day 5
3,350* infusions to be tasted

by a dozen men, each sales day; but each buyer is supposed to taste them all, in about an hour and half, or about 40 minutes! The fact is no buyer tastes more than a dozen or 20 samples, so that competition is out of the question.

THE PRICE OF PEKOE SOUCHONG.

Colombo, Dec. 7th.

DEAR SIR,—I notice a correspondent in your paper quotes Fair Pekoe Souchong in the Colombo market at 22c 24c, against 30c in London, the standard being Messrs. Geo. Wilson & Stanton's as per their weekly telegram.

Though I have attended the local sales regularly I have not been able to purchase pekoe souchong equal to the London standard as under 30c—32c, and therefore shall be glad if your correspondent will tell me where I can buy at the price he quotes: at that price I can take a considerable quantity.—Yours faithfully, A BUYER.

THE PRICE OF PEKOE SOUCHONG.

DEAR SIR,—I see "A Buyer" disputes the fairness and truth of the inference drawn by me in comparing London and local averages for P. S., and asks me to inform him "where he can buy fair Pekoe Souchong at 22 to 24 cents." This question reads almost like a joke, and the answer is very easy, namely:—At the Colombo sales every Wednesday. What he intends to say, of course, is that the lots that are sold in Colombo every week at 22 to 24 cents are not average Pekoe Souchongs as sold in London. Well, who is to decide? I don't suppose any seller who accepts the 22 cents will rise up in his wrath and in his own name fight the question out. So all we can do is to fall back upon the published price lists, and on what we, nponcountry, know of our neighbours' plucking and make. I take the London value to be the average of all P. S.'s sold, if not such "as usually made" by one or two big factories, usually under the average. My question, therefore, is very natural, "Why should the Colombo average be 6 to 8 cents lower than the London, as seen in every week's local price list?" I would like to sell locally myself, but do not for this reason; though I see tea of my neighbours (the plucking and making of which I know) being sold at 22 cents, and I cannot understand

WHY.

* Correct quantities required for the right answer.

THE PRICE OF PEKOE SOUCHONG.

Colombo, Dec. 18th.

DEAR SIR,—I was very much surprised at "Why"'s first letter, but his second throws a little light on his astonishing statement that Pekoe Souchong equal in quality to those in London selling at 6½d per lb. are sold in Colombo at 22 cents per lb. Of course to anyone who is selling or buying on both markets, and so knows by the inexorable logic of account sales the relation of Colombo to London prices, the above statement is absurd. But "Why" states that he supposes the quotation which appears in your valuable paper every week refers to the average price of Pekoe Souchong sold for the week on the London market; if he reads carefully he will see that you quote the price of "Average Pekoe Souchong" of one uniform quality which does not vary, as you explained in answer to a letter which appeared in your paper some time ago.

The latest mail from London is dated 26th ultimo. On referring to Messrs. Gow, Wilson & Stanton's circular of that date I find the lowest quotation for pekoe souchong is 4½d, only a single package, it is true, but a large proportion sold at between 5d and 6d, some from estates of high altitude, and good reputation. At about this date your quotation for fair pekoe souchong was 6½d. This of itself is, I think, sufficient answer to "Why"'s question.

I herewith send a sample of pekoe souchong sold in London at 5½d and sent to me as a buying standard. If "Why" can tell me where I can buy tea equal to this at 25 cents (3 cents over his quotation for pekoe souchong worth in London 6½d) I shall esteem it a favour.

If "Why" really thinks there is a margin for profit of 1½d between the Colombo and London markets, why does he not buy all he can get? It is not often such a good thing offers.

One other thing I may as well mention: tea sent down for sale on this market is not always what it is described to be. 12 chests described as pekoe souchong was sold at 12 cents; it was not pekoe souchong at all, but common red leaf.—I am, dear sir, yours faithfully, A BUYER.

TAPIOCA JELLY.—Soak a quart of a pound of tapioca in water enough to cover it. Let it stand several hours, then stir it into a pint of boiling water. Simmer it slowly till it appears semi-transparent. Sweeten it to taste, and flavour with wine and nutmeg if approved of by the physician. Turn it into cups or molds.—*Florida Despatch and Fruit Grower.*

LOW-FIRED TEAS.—We learn that telegrams have been received in Colombo announcing that the first Ceylon teas low-fired according to Mr. Davidson's system have sold in Mincing Lane at good prices, showing an advance on ruling prices of 1d to 2d, thus proving the success of Mr. Davidson's method.

THE ZANZIBAR CLOVE TRADE.—A proclamation signed by the Sultan of Zanzibar, and countersigned by Mr. Gerald Portal, the British Resident was issued on November 27th, declaring that a duty will be levied on all the organs of florescence of the clove-tree, whether clove stems, buds, or seeds, after December 2nd next. The object of the measure, Reuter thinks is to increase the value of the clove stems, upon which no duty has hitherto been paid. We should rather incline to the belief that the measure is aimed at the discouragement of the exportation of parts of the clove other than the buds.—*Chemist and Druggist, Dec. 5.*

SISAL HEMP IN THE BAHAMAS.

EDGAR MAYHEW BACON.

On Inagua Island, the most southern of the Bahamas group, there is a stone building known as the salt house, under the ample roof of which frequently sounds the clatter of a vigorous donkey engine. Entering the building, the first sight to meet the eyes is a heap of sharp pointed, deep green leaves, which a negro is feeding, one by one, into a rapidly revolving machine. At his right lies a pile of long, powerful fibre, such as is used in rope making. Near by is a cart into which a boy is throwing the vegetable waste or pulp which he gathers from beneath the machine. This bagasse, as it is called, is wet with sap, and so strongly acid as to kill other vegetable growth with which it may be brought in contact. The fibre is the product, the bagasse the refuse (as yet unused) of the sisal leaves. There are about four feet and a half in length, averaging longer than do the leaves of the same plant grown in Yucatan. At the base, where they have been cut, they are thicker than a man's hand and from three and a half to five inches in breadth, running from this to a point so fine and hard that it can be used as a stiletto. The edges are armed with slight spiny serrations. An attendant with knife and maul removes the sharp points, crushes the thick ends, and divides each leaf longitudinally. Each strip is fed, by the negro in charge, into the mouth of his machine, through which it is carried half its length by the rapidly-revolving cylinder. It is then drawn out, which scrapes the bagasse from it. Reversing the strip, the operation is repeated and the result, a long, white "switch" of fibre, is added to the pile already noticed. The fibre is now washed in salt water (which gives better results than if fresh water is used), after which the hanks are hung in a drying house or better still, in the sun till perfectly dry, when the material is ready for baling and shipment. An old turtle tank or "crawl," cut out of the soft calcareous rock, with a small hole in the wall, which divides it from the ocean, so that the tide can flow in and out, makes an excellent basin for rinsing the fibre.

Sisal closely resembles the manilla hemp of the Spice and Philippine Islands, when prepared for market, and is not unlike it when growing. In Yucatan they are generally known as Hennequin. They possess in varying degrees the strength, length, and luster of fibre upon which the market value depends. The Saqui, botanically known as *Agave Isth.*, introduced some years ago into Florida, under the name of *Agave Sisalana* and often called Magney, has received the greatest attention from Mexican (Yucatan) cultivators. The plant which is being cultivated in the Bahamas was at first called "Pita," and, although greatly resembling the Saqui, is considered a superior kind. A number of more or less worthless plants, having apparently the same general characteristics, are to be found throughout the West Indian Islands. A gentleman in Jamaica, with five hundred acres prepared for hump planting, recently showed me the plants which he proposed to use, and which he imagined to be good Sisal. They were the valueless Kerato, the leaves of which might deceive any but an expert, but which upon being cleaned produce a fibre so weak that its cultivation would be utterly futile.

A full-grown Sisal plant has sixty to eighty great leaves, growing around a common centre, which incline from a group of upright, undeveloped ones in the middle of the cluster to an outer circle that is nearly horizontal. Many leaves measure over six feet in length, but the average length of the "ripo" ones, as already stated, is four and a half feet. The average number of leaves which may be procured from each plant annually is over forty, being in excess of the Yucatan production. The separation of the leaf from the plant is made with a knife near the base, and ripe leaves may be cut from two-and-a-half-years-old plants, although the length of time required for maturity differs in different localities. One cutting does not exhaust the plant. It may be

stripped annually, or even more frequently, for twenty years, and when it shows sign of age may be replaced by a sucker, of which the careful Sisal cultivator will be sure to have a nursery full for such emergencies. The propagation of the Sisal is either by seeds or suckers. The latter spring up around the mature plants constantly, and should be carefully removed because they sap the life of the parent and also for the reason that they are most valuable for replanting. When plants remain uncut for too long a time, a huge flower stalk shoots up from the centre to the height of eighteen feet. After having flowered and matured its seeds, the plant invariably dies.

Experienced growers use six hundred and fifty plants to the acre, in rows eleven feet by six feet distant from each other. This will give room for the laborers to walk between the rows without being wounded by the terrible spurs which, like a cluster of keen spears, make each plant a menace to the unwary. Besides this, the closer planting would result in the piercing of innumerable leaves every time the wind blew, and the consequent destruction of much fibre. Stabs and bruises mean discoloration, and the expense of sorting damaged lots apart from the proportional loss would be an added and not insignificant item in the labour account of a plantation. Many people who have caught the "Sisal fever" are planting acre after acre, expecting nothing less than that the farms, when planted, will take care of themselves. To be successful in this enterprise requires unceasing activity and care. One must be Argus-eyed. One season of poor prices, with the consequent discouragement which is apt to follow in the case of nine small proprietors out of ten, in a country where the peasantry are all negroes will result in an overgrowth of suckers and the paling of mature plants till nothing short of absolute clearing and starting anew will save the farms. There is no cultivation where system and perseverance are more necessary to success. The dropping of the seed from a single "pole," if not watched and attended to immediately, will produce little spears enough to destroy a hundred plants, and I have frequently seen a dozen suckers start up around and under the leaves of their parent. After such crowding, the leaves would be worthless, even could they be reached; but no man, unless arrayed in metal armor strong and stout enough to withstand the thrust of steel, would be so foolhardy as to attempt to penetrate such a growth. What I want to impress is the fact that without that patient and systematic care, which I have no where observed as characteristic of the unled negro, a field of Sisal is as valueless as a field of mullein.

The hardness of the Sisal is something wonderful. It grows best on lands which seem good for nothing else. Rock land, where the hardy sage, the sword plant, or cactus crowd the stunted, gnarled hardwood trees; where the fissures in the sun-hardened limestone are filled with a dry, sandy soil, and hardly a barrowful of that to the acre, will produce Sisal. If hard pushed, it will grow in the air, without soil, I have twelve living plants which I kept shut up for eighteen months in a cigar box without light, air or water. But such growth as will result in a marketable commodity is a different matter. That requires a soil not too rich, which induces fatness and loss of fibre, nor too poor, or the plant grows dwarfed. The ground must not be too wet or too dry.

When the right spot has been found; when the selection of seeds or suckers, the preliminary preparation, has been accomplished; then, the choice of season hastens or retards the work of preparing the ground for the reception of the plants. Of course there is no winter; no frost or cold to contend with; no blizzard to calculate for. But there are rainy and dry seasons. One must calculate so that the necessary burning of cut brush and trees will not occur when the fires are liable to be extinguished by the violent down-pour of the "winter" rains, nor the planting delayed until the dry months interfere with the advance of the young plants.

All the ground is gone over first with the machete¹ a long, heavy, cutlass-like knife, which the negro uses either as a tool or weapon. All trees and underbrush are cut down except the very large ones, which require an axo. Then the stumps are grubbed up so far as they are likely to interfere with the work. Next, fire is employed, and quickly runs over the acres where the negroes have toiled in gangs with their cutlasses. In this work of clearing, women are often found more satisfactory as laborers than men, and they receive but thirty-six cents where the men get fifty cents. Few laborers are paid by the day. Task work, i.e. so much for clearing a piece of land of a given size, called a "task of land," is the usual method. In clearing brushland in the Bahamas, one-fourth of an acre is a task. When, at last, all the clearing and planting has been done and thousands upon thousands of perfect plants, in absolute symmetry of arrangement, with unbroken ranks, their rich green showing no blemish, stretch before the eye, the spectator (especially if he happens to have a financial interest in the plantation) feels that there is a beauty apart from mere picturesqueness.

The present boom in Sisal in the Bahamas, although, like all excitements of the kind, doomed, without doubt, to considerable depression in the future, will not be without beneficial results. Even with the great falling off in enthusiasm which the next two or three years are likely to bring, there will remain a new industry, a source of greater prosperity to a people who have been for many years almost inactive.—*Nassau Guardian*.

BOTANY AND NOMENCLATURE OF CACAO WITH DESCRIPTION OF TYPICAL FORMS, Etc., Etc.

Under this heading Mr. Hart, Director of Botanical Gardens in Trinidad, contributes an elaborate article to the *Agricultural Record*, as follows:—

The name which Linnæus conferred upon this plant is derived from the Greek *Theos* (god) and *Broma* (food) or "Food for the gods."

There are several species of the genus, which is native of tropical regions extending from Mexico to Brazil, and among the known species are the following:—*Theobroma bicolor*, *T. guianensis*, *T. sylvestris*, *T. ovatifolia*, *T. angustifolia*—all said to be distinct from our cultivated *Theobroma cacao*, L., and its varieties, or the kind from which the major quantity of the marketable product known as cacao or "cocoa" is derived.

The Mexicans give to *Theobroma cacao* the name of *Cacaoquahuitl*, which has been in a great measure retained in the word chocolate. The trees of *Theobroma cacao* grow in some places to forty feet in height, the writer having seen them of this size in the province of Veragua when travelling there in 1885, but the usual height of the Trinidad tree averages about fifteen or twenty feet, the lateral diameter of its branches being about the same measurement. In Grenada, Tobago and St. Vincent the tree is generally of smaller size.

The botanical characters of the genus are given in Griesbach's *Flora of the British West Indies*, p. 91, as follows:—

ORDER STERCULIACEÆ.

TRIBE BUETTNERIÆ.

Calyx 5 partite, colored. *Petals* 5: limb cucullate, with a terminal, spatulate appendage. *Colum* 10-fid: fertile lobes bi-antheriferous; anthers bilocular. *Style* 5-fid. *Fruit* baccate, 5-celled: cells pulpy, polysperous. *Embryo* ealbuminous: cotyledons fleshy, corrugate. *Trees*; leaves entire; pedicels fascicled or solitary, lateral.

The description of our species is given in the same work in similar terms:—

T. Cacao, L.—Leaves oblong, acuminate, glabrous, quite entire; flowers fascicled; pericarp ovoid-oblong, 10 costate. *Calyx* rose-colored; segments lanceolate, acuminate, exceeding the yellowish corolla; pericarp yellow or

reddish, leathery 6 to 8 inches long. *Habitat*, Trinidad—*De Schach*, *Naturalized in Jamaica!* *Dist.* St. Lucia! *Anderson*, (*Guiana and Brazil!*)

The various names under which the varieties of this tree (*Theobroma cacao*) are known do not constitute species, but must be merely considered as varieties of one original species. These varieties probably owe their origin to seed variation, together with the influence of soil and climate, and to enumerate the whole of their names would serve no useful purpose.

Mr. Morris's classification* was based upon the nomenclature of some of the best estates in Trinidad and has stood the test of ten years' criticism without serious contradiction, and may well be adopted for Trinidad with slight modification. It must be admitted that the local nomenclature of various districts differs much, one with another, and it would therefore be a hopeless task to attempt to reconcile these names. It is but patent to a close observer that there are certain characters of cacao more strongly marked than others, as exemplified in the varieties known as Criollo, Forastero and Calabacillo, though Mr. Morris contents himself with forming them into two great classes, "Criollo and Forastero," and he gives the Calabacillo as a variety only of Forastero.

Judging from a series of observations it would be better I am inclined to think, to make three classes, placing Criollo as Class I., Forastero as Class II., and Calabacillo as Class III., being the lowest type of the species.

CLASS I. CRIOLLO—OR FINE THIN-SKINNED VARIETIES.

1. Var. *a.* Amarillo.
2. " *b.* Colorado.

CLASS II. FORASTERO—OR THICK-SKINNED CACAO.

3. Var. *a.* Cundeamor vorugosa amarillo.
4. " *b.* " " colorado.
5. " *c.* Ordinary amarillo.
6. " *d.* " colorado.
7. " *e.* Amelonado amarillo.
8. " *f.* " colorado.

CLASS III. CALABACILLO—OR SMALL-PODDED, THICK, SMOOTH-SKINNED, FLAT-BEANED.

9. Var. *a.* Amarillo.
10. " *b.* Colorado.

The finest cacao is by general consent admitted to be produced by the Criollo variety, and this is assumed to be identical or similar in character to that called the Caracas variety. In the Consular Report on the agricultural condition of Columbia, Consul Dickson mentions that "the variety chiefly grown in Columbia is different to that of Venezuela, which produces Caracas cacao, the pods being much larger, and containing a greater number of beans, but as the number of pods produced by a tree is greater, it is probable that on the whole the Venezuelan variety is the more productive of the two. The quality of Columbian cacao is little, if at all, inferior to that of the Venezuelan, but it is little known in commerce, as only an insignificant amount is exported, the supply scarcely satisfying the demand of the country."

What this variety spoken of by Consul Dickson may be, we have no means of correctly ascertaining at present, but from the comparison with the Caracas variety given by Mr. Dickson we might assume that it was very near to, if not synonymous with our Forastero, and it is to be noted that such a variety would also be "Forastero" or foreign to the Caracas people.

Dr. Trimen of Ceylon, in his annual Report for 1890, falls into the error of interpreting the word "Criollo" as being synonymous with "wild."

It is well known, however, that the word is never used in this sense in the West Indies, the true interpretation of the word "Creole" being—one born

* "Cacao, How to grow and how to cure it." (Jamaica, 1882.)

† No. 1, red Creole; No. 2, yellow Creole. Nos. 3 and 4, Cundeamor, is derived from the Spanish name of the "Cerasee" (*Momordica Charantia*), which possesses a peculiar warted appearance. Thus the name means *Momordica*-shaped, rough red or yellow cacao. Nos. 7 and 8 are Amelonado or melon-shaped, red and yellow cacao. Calabacillo, calabash-shaped cacao, red and yellow.

in a country or one belonging to a country. With European Anglicans the word "Creole" is generally supposed to have reference to a mixture of races, but it is not used in that sense here.

For instance a child born of white parents in any West Indian Island, or even on the mainland of Central and South America is a "Creole," and just as much so as a black or coloured child would be. In fact "Creole" would be better translated as "native" than as "wild" or coloured, a black or coloured child being just as much a Creole as a white one. An English clergyman lately traveling in Trinidad was much surprised to find that the word Creole was used in this sense here, and even when shown that the use of the word in his sense would often subject him to ridicule, still he said he was not inclined to allow that the West Indian interpretation was right, but felt inclined to follow his own. This gentleman was writing a book, and possibly we may hear more of his conservatism later on.

It is important that the sense in which the word "Creole" is used should be fully understood as we have Criollo" as our first variety of cacao.

If we interpret the words Criollo cacao as native cacao, and Forastero as foreign cacao, and Calabacillo cacao as calabash cacao, we shall have a better definition of terms, and prevent further misapplication of the word "Criollo." The Calabacillo is so named from its fruits resembling those of the calabash tree (*Crescentia cujete*, L.)

Dr. Trimen (Annual Report, 1890,) remarks that these names appear to have had their origin in Trinidad, and doubts whether the first or Creole was "over really a native plant there." The misunderstanding of the word Creole probably leads him to this conclusion, for how could it be *Native* or *Creole* (Criollo) if imported into Trinidad, unless its name was imported from South America with it, and if so it should be known as the Criollo of South America and not simply *Criollo*. The word Forastero is also applied on the Main to the same cacao as in Trinidad, for they term it "Trinitario" in contradistinction to their own Criollo, and certainly a plant of Trinidad would be Forastero or foreign in Venezuela or any other part of Central America, and therefore their Forastero being a foreign cacao and supposed to have its origin in Trinidad, would properly be the Criollo of Trinidad if the word was used in the correct sense.

It may be possible, however, that Criollo cacao is a native of both countries, and that one has as good claim to it as another, but the balance of probability appears to be that its origin can be rightly traced to South America as indicated by Dr. Trimen, but there at present appears no ground of proof in support of the proposition.

Dr. Trimen also repudiates the authenticity of the word Criollo as attached to plants sent him from the Trinidad Botanic Gardens, and turns them into Forastero apparently on account of their being dissimilar to "the Old Ceylon Red cacao, also called Caracas" (Report for 1890,) but he allows a little later, that the Forastero sent from Trinidad to Ceylon is in the opinion of a large grower gradually changing its character and "becoming more like the Old Ceylon Red," or in other words, is reverting to its original type through the influence of the soil and climate in which it grows.

If therefore it is possible for Forastero to revert into the Caracas or Criollo, this circumstance goes very far to sustain the supposition that Forastero is merely a descendant of Criollo, or that Criollo is a descendant of Forastero: the change being brought about by circumstances of soil and climate in each case. That such a change is quite possible and very probable, is shown by the fact that our best scientific botanists do not find sufficient distinctive characters (notwithstanding the differences in the form, size and colour of fruit, leaf and tree) to make more than one species of all our cultivated varieties; which as Dr. Trimen truly says, probably trace their origin to a common wild parent.

The characteristics of the Criollo cacao are the

thinness of its pod, its rounded beans and pale colour of the interior of the bean on section. The leaves of the tree are small when compared with the Forastero varieties and the tree itself is not nearly so sturdy and thriving, and does not produce such regular and abundant crops as the Forastero and Calabacillo varieties. The skin of the bean is thinner, and the interior has but a small proportion of that bitter flavour which is characteristic of the unfermented bean of Forastero and especially that of Calabacillo.

The flattest beans are those produced by pods of the Calabacillo type. The beans of Forastero are intermediate between these and the rounded form of the Criollo.

The above sketch of sections of the beans of the three typical varieties, shows the difference in form which occurs, but still there will be found intermediate forms hardly reconcilable with any of the figures, so that they are to be taken as representative only of the typical varieties with some latitude.

There are rounded beans* to be found in almost every pod towards its extremities, but the proportion of rounded beans in Calabacillo is very small indeed, and the yield of this form of bean increases only as the character of the pods approaches the Criollo type. The Calabacillo, or that class which gives small, rounded and smooth pods and flat beans, having a bitter taste, is the lowest type of cacao that is grown, and requires the greatest amount of skill during treatment to bring it into marketable form, the process of fermenting it, taking more than double the time required for Criollo. The tree however is the stoutest grower and the hardiest of all the varieties and will thrive on poorer lands, and on lands on which it would be impossible to grow the finer kinds.

Trees of the Forastero type are also strong growers, and its varieties are suitable for most lands in which cacao can reasonably be expected to thrive. It approaches the Calabacillo type by the Anielonado variety, both red and yellow, and certainly stands as a large intermediate and somewhat variable type between Criollo and Calabacillo. In general the Forastero type has a thick skin. It approaches the Criollo in form, or runs into Criollo by its variety *Candeannar verugosa*, red and yellow, but trees may be found bearing pods which are hardly to be distinguished from the Criollo on the one side and the Calabacillo on the other, thus showing the breadth of form covered by this kind.

It becomes a question, therefore, for the planter to ascertain the character of his land with as much accuracy as possible before deciding what variety of cacao he will plant. If very poor he can rely upon Calabacillo only. If from moderately good to fairly rich, he should rely upon the varieties of the Forastero type, but if rich and lasting ground, only the best types of Criollo should be planted.

The generality of plantations are however of so mixed a character that it is difficult to separate one kind from another, though there cannot be any doubt that it would more than pay for any extra trouble were the system of planting each type in separate fields faithfully carried out.

* The word "bean" is incorrect, but as it is the common form of expression among our cacao planters, it is used as being better understood than any other.

* Dr. Chittenden in *Agricultural Record*, vol. ii., p. 107.

The contract system which prevails in Trinidad is probably more to blame for the mixed character of the fields than anything else. The contractor has perhaps in the first instance planted from seeds supplied to him—all of one kind. In supplying first vacancies he uses stronger and larger growing plants, and in places where the plant has refused to grow after planting twice or thrice, he will (rather than lose a count of a tree) put in a plant of the strong-growing Calabacillo.

In length the leaves of Criollo vary from 5 to 12 inches and from 2 to 4 inches in breadth. Forastero cacao gives the largest leaves of all. For the sake of accuracy I have made special measurements of some growing in the Royal Botanic Gardens and find that they vary from 9 to 21 inches in length, and range from 2½ to 6 inches in width.

The leaves of the Calabacillo type are shorter and wider in comparison with their length than either Criollo or Forastero.

It must be understood, however, that these measurements are taken from extreme forms, and that the nearer the trees approach other varieties, so also do the leaves vary in size and shape.

Cacao is said to have been cultivated largely in Jamaica some two hundred years ago, but according to Long, in his History of Jamaica, the plantations were destroyed by a "blast." Mr. Morris mentions in his pamphlet that in Trinidad also the trees were visited by a blast "some time during the last century." He interprets the word "blast" as a "blow or hurricane," but the word in East Anglian brogue is also given another meaning. "Blast" is there synonymous with "blight," and this is confirmed by Walker's Dictionary as follows: (*to blast—to strike with some sudden plague*). Either interpretation would however fully account for the destruction of plantations, especially when taken in conjunction with the high rate of duties which was imposed on the article in England at about the same time. What-ever the cause, the cultivation of cacao in Jamaica received a wonderful check, for in 1671 Long states there were as many as sixty-five walks in bearing; while in 1882 it was only grown in isolated instances until the value of the product was brought into notice by Mr. Morris, when the cultivation became largely increased. The introduction to Jamaica was probably effected by the Spaniards as the English only came into possession of that island in 1655, or sixteen years previous to the date mentioned. One species is mentioned by a writer (Martius) as having been found in Jamaica (*Theobroma sylvestris*) but this would appear to need confirmation before being accepted as fact.

There appears to be little doubt, however, that *Theobroma cacao* is a native of the Northern territories of South America, and as the character of the flora of the mainland is closely approached by that of Trinidad it is quite possible that this species is indigenous to Trinidad, or was introduced at some remote time into the island.

Many writers agree that the flavour of cacao is dependent upon the soil, and in this they are probably correct, but much must also depend upon the surrounding conditions, viz.: moisture, exposure, and temperature, in their respective order, and perhaps more is to be attributed to these than to the soil, although all of them, it is freely admitted, may have a direct influence on flavour and quality.

Spon's Encyclopædia gives *Theobroma angustifolia*, *T. bicolor*, *T. guyanensis*, *T. microcarpa*, *T. ovalifolia*, *T. speciosa*, *T. sylvestris* as producing commercial cacao, but we cannot learn upon what authority.

When travelling in Central America in 1885 I found *Theobroma bicolor*, Humboldt and Bonpland, indigenous in the province of Veragua, United States of Columbia. It was known as "tiger cacao," so named from the rank smell of the seeds. It is not in general use by the inhabitants, though it is said to be used in some manner by the Indians. It has also the name of "Indian chocolate" and "Wariba," the latter being the Indian name, and appears to suggest some connection with the "Wari" or wild hog, probably one of the peccaries (*Dicotyles*) which are known to emit from a gland on the back a strong-smelling fluid.

It must be doubtful, therefore, if commercial cacao is produced by *T. bicolor*, and such a supposition would also throw some doubt upon any species producing commercial samples other than our *Theobroma cacao*, L., though we do not think it impossible or improbable that they should do so, and would rather infer that it would be possible by bringing them into cultivation in Trinidad, to be able to add to the variety of our produce and perhaps to improve it by hybridization with other species.

The kernel of *Theobroma guyanensis*, Wild, is said by Don to be white, and good eating when fresh. He also says that the seeds of *T. bicolor* are mixed with the seed of the common cacao (presumably *T. cacao*).

According to Aublet's illustrations the pods of *Theobroma guyanensis* are small and oval, distinctly marked with five raised ribs, and the leaves are much like those of *T. cacao* but more cordate at the base. The fruit of *T. sylvestris*, from a plate by the same author, is small, smooth, yet still showing the five divisions of the pod by slight depressions or lines on the outside at equal distances from each other. The leaves are small and suggestive of the ordinary form borne by "Criollo." The pod of *T. bicolor*, Humboldt, is woody in texture, hard and dry, and specimens can be kept for any length of time. I have a specimen, collected in 1885, in the herbarium of this department, and also specimens of the leaves and flowers.

CHINESE CINNAMON.

BY HENRY HUMPHREYS, M.L.C., HONGKONG.

It is generally supposed that Chinese cinnamon is the same thing as cassia, but there is reason to believe that this is not the case. One day I noticed our Chinese manager take a piece of bark out of his pocket, cut a bit off, and put in his tooth. He explained that it was cinnamon, and that it was used to stop his toothache. I looked at the bark and asked him if it was not cassia he meant. He smiled complacently and remarked, "One does not pay 5 dollars an ounce for cassia." I have since investigated the matter, and although unable to identify the "Chinese cinnamon" plant with Ceylon cinnamon, owing to the impossibility of obtaining the flowering branches, the results of my inquiries tend to show that Chinese cinnamon differs very materially from ordinary *Cassia lignea*, if only in the fact that it is certainly obtained from very old wild trees, whereas the cassia of commerce is obtained from cultivated trees only (Ford).

I found the six samples I worked on and which I have sent to Mr. Holmes for further investigation, to differ from cassia in appearance, taste and smell, and to contain little or no mucilage. On the other hand the iodine test gave a similar reaction to cassia. Owing to the costly nature of the bark, I was able to experiment only on very small quantities.

The Chinese call their cinnamon bark by different names and pay more in some cases for an ounce of "cinnamon" than a picul (133½ lb.) of cassia.

A cold aqueous infusion of all six samples yielded with iodine a bluish-black coloration, but with $HgCl_2$ there was no evidence of the presence of mucilage. The aroma of all six came near that of Ceylon cinnamon, but in some cases there was a pungency more consistent with the idea of their being derived from cassia.

One important point, however, I have been able to ascertain is, that "Chinese cinnamon" grows wild in Annam much further south than the West River in the Kwangsi and Kwangtung provinces, where cassia is cultivated.

The Chinese adopt the common name of Kwei for both cinnamon and cassia, but distinguish the two by an additional name; for instance, ordinary cinnamon is Jan Kwei and ordinary cassia Kwei pi.

Chinese cinnamon is never exported, owing to the heavy prices the Chinese pay for it. There are a good many varieties, all of which grew wild in Annam, in the neighbourhood of a mountain there, called Ching Fa. The most expensive kinds come

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for January :—

THE SCHOOL OF AGRICULTURE.

DISTRIBUTION OF PRIZES.

THE ANNUAL distribution of prizes at the School of Agriculture took place on the 28th November, 1891, under the presidency of His Excellency the Governor.

Among the company, which was the largest ever assembled at the School on such an occasion, we noticed the following :—

The Hon. the Colonial Secretary, the Hon. W. W. Mitchell, Seneviratne, Grinlinton, Abdul Rahiman, and Dr. Anthonisz, Messrs. A. M. Ferguson, c.m.g., Wm. Ferguson, H. W. Green, J. B. Cull, J. F. de Saram, J. W. C. de Soysa, and J. H. Barber, Mr. and Mrs. F. Beven, Mr. and Mrs. and the Misses E. Ludovici, Mr. and Mrs. and Miss Daniel, Mr. and Mrs. and the Misses Swan, the Misses Beven, Watson, Langenberg, Dr. and Mrs. and Miss Keith, Mr. and Mrs. Jacob de Mel, Mrs. James Pieris, Mrs. C. Drieberg, Miss Morgan, the Committee members of the Gramaraksha Samagama, Mr. Sangarapulle, Mr. and Mrs. C. B. Nicholas, Mr. and Mrs. C. Kriekenbeck, Mr. and Mrs. Alport, Dr. Drieberg, Mrs. E. Joseph, Misses Vanderstraeten and Drieberg, Mr. Richard de Silva, &c., &c.

The building was gaily decorated for the occasion. At the main entrance was erected a triumphal arch bearing the inscription "Welcome to H. E. Sir Arthur Havelock, k.c.m.g." The drive from the gateway was left unadorned, evidently with the idea of securing for the visitors a good view of the grounds; but from the main entrance to the school and along the long corridor till the large halls at the posterior end of the buildings were reached, a profusion of

flowers, foliage and fruitage tastefully put together adorned the walls and pillars or hung from the roof. The usual embellishments, consisting of mosses, coconut leaves and bunting were much improved by the addition of arecanuts, dates, sugarcane, tamarinds, cacao, &c., and hundreds of miniature bouquets of roses and other flowers that hung from festoons. The adornment of the principal hall gave evidence of much care and trouble, and here in addition to the other decorations were groupings of foliage plants, and a splendid collection of the choicest flowers in vases and cornucopias. The whole length of the long corridor was also strewn with rose petals, which however became a source of danger on the cemented floor and had to be swept aside. A carpeted space in front of the platform was reserved for the Governor's party, and there the floral arrangements were particularly striking and elegant.

The following is the PRINCIPAL'S report :—

The pleasant duty falls to me today, of extending to Your Excellency a hearty welcome to the School of Agriculture, on this the first occasion on which you have come to preside at our annual prize-giving.

You are not altogether a stranger, sir, to this institution, for with your well-known promptitude to acquaint yourself with the condition and needs of all departments of Your Excellency's Government, you visited the School shortly after your arrival in the island, and on that occasion expressed yourself, to quote Your Excellency's own words, "much interested in this useful institution." The pleasure of welcoming you, sir, is moreover greatly enhanced by the fact that within the short time that has elapsed since you assumed the reins of Government, you have given unmistakable evidence of your kind and encouraging sympathy with the cause of agricultural education in this country. We who are engaged in

this branch of agricultural work have considered the past year a most eventful one; and for the provisions that have been made, and the facilities that have been granted us for the carrying on of our work, I take this opportunity of thanking Your Excellency in my own name and on behalf of the staff of this School.

Since the foundation of the institution the students have had a great struggle with the adverse natural conditions attaching to the situation of the greater part of the land available to them for cultivation,—conditions which though science can undoubtedly cope with and alter, were altogether beyond our control, inasmuch as the drainage outlet which should carry away the excess of moisture that remains to, in a great degree, sterilize our land, is under the care of another public department which has not yet solved the problem of the drainage of the Cinnamon Gardens. To meet the difficulties in the way of raising such crops and carrying on such field-works as it is necessary to do for purposes of illustration in the teaching of the science and art of agriculture, we have, during the past year, received a grant of land, over 40 acres in extent and immediately adjoining the School premises, on which the necessary operations connected with our agricultural course may now be practised under more favourable circumstances than hitherto.

Another matter I have to record is the possession which we have come into of a good type of stud-bull, an agent that has for long been desiderated at this centre of agricultural education, which is not least concerned with the improvement of the stock native to the island.

Provision has also been made for the employment of a Government Veterinary Surgeon who is to be attached as a lecturer to the School of Agriculture. I have already been introducing our students to the elements of veterinary science (a subject closely allied to agriculture) with the knowledge I possessed of its principles, gathered under a press of other work which left me little opportunity for attending to and mastering its practical details to the extent I should have wished. But I trust I shall very shortly have to resign this part of the work of the School into more competent hands, and that the teaching of the expected veterinary surgeon, and the practical instruction which our students will receive at the veterinary hospital it is intended to erect on these grounds, will turn out men, who, as Veterinary Inspectors, will carry on a most useful and important work.

If the Superintendent of the proposed Technical Institute were to join forces with us in the cause of education, you will admit, ladies and gentlemen, that these old walls which have experienced many vicissitudes will support a great educational stronghold, and enclose a most important educational centre.

There have altogether been about 40 students turned out by the School, 6 of whom are employed as agricultural instructors by Government and 5 privately. Of the rest some are engaged in the cultivation of land on their own account, notably the students from the Southern Province, while 3 or 4 have left the island and found employment under the Straits Settlements Government.

Mr. Laurence Perera who was so successful with cotton at Nikaweritiya is doing excellent work at Kuliyaipitiya. His paddy cultivation according to different methods has given useful results which I shall not cumber this report with, but I may say that its success has been testified to by the Government Agent and Assistant Government Agent of Kurunegala. His experiments with cotton have brought out the fact that the Bourbon variety may be remuneratively grown in the district; and Mr. Perera has also given his neighbours practical lessons in the cultivation of arrowroot, potatoes and onions, all of which have been found suited to the locality.

At Navadimunmarai in the Batticaloa District, Mr. Chinasiyagam brought an extent of 26 acres under the cultivation of the improved plough with most satisfactory results. He reports that the villagers in his district closely watched the several processes he went through, and that six cultivators borrowed his implement for working their fields, while a few applications were made for Massey & Co.'s cheap ploughs.

Mr. Tiathonis, Agricultural Instructor at Madampe is giving all his attention to the encouragement of pepper and cacao cultivation which the Government Agent of Ratnapura is very wisely urging the natives to adopt, by distributing seeds and plants with instructions as to cultivation and curing.

The splendid work which is being done in Happy Valley is I doubt not well-known to Your Excellency. Mr. Hoole, the Agricultural Instructor, reports the comparative immunity of the paddy cultivated by him both from insect attack and the evil effects of drought. It is quite apparent that the villagers about this centre are being appreciably influenced by the work at Happy Valley, and encouraged to carry on the systematic cultivation of different kinds of garden produce.

The Agricultural Instructor at Kadugamawa, Mr. J. A. P. Samarasekera, reports that he has introduced horse-gram, green gram, and arrowroot to the natives, to whom these crops were quite unknown, and that they have already begun to grow and prepare arrowroot for consumption.

Mr. P. Samarasekera, Agricultural Instructor at Akmimana, has been engaged in the cultivation of 10 acres of paddy and 4 acres of arrowroot, dhall and vegetables. He reports that two ploughs have been purchased by the villagers, and expects that more will before long be imported into the district.

Mr. Ranasingha writes from Kolonna Korala that he has been distributing dhall seed from trees raised in his experimental garden, and that the villagers are beginning to cultivate this most desirable product in their own gardens.

Mr. J. W. P. Samarasekera, Agricultural Instructor in Kegalla District, furnishes me with an interesting report in which he states that he has conclusively proved to the cultivators in his vicinity that he is able to produce twice the ordinary crops of paddy by his method of cultivation, and that his plough has been in great requisition among them. The crops, whose cultivation has been demonstrated by this instructor are arrowroot, tobacco, dhall, green gram, horse-gram, and Indian corn, besides paddy.

Mr. Chelliah, Agricultural Instructor at Nintavur, gives an interesting account of the cultivation of 35 acres of paddy land, which yielded 1,140 bushels, or an average of 33 bushels per acre, and showed when all cost of cultivation was deducted a profit of nearly R1,000. Mr. Chelliah reports that the cultivators in his district are following his methods of culture, that many applications have been made for the loan of his ploughs, and that half-a-dozen cultivators have purchased improved implements. He also mentions the interesting fact that he has found burnt lime, when applied to the land before sowing, a certain preventative against insect attack. "My experience leads me to infer," says this Instructor, "that everything connected with paddy cultivation is under the control of the influential irrigation Vanuiyas, who if they be trained agriculturists will have grand opportunities for improving paddy cultivation and making it a successful and profitable industry."

Mr. Rodrigo is still working well at Bandara-gama, where since his appointment as Agricultural Instructor the attendance at the village school has considerably increased.

I must ask your indulgence, sir, for the length at which I have referred to the results of our Agricultural Instructors' work, but I am anxious that there should be some record of it, and that Your Excellency as well as the public should know something of the outcome of our teaching in this school. It is supposed by many that our great object is to get the goyiya to cultivate with Howard's Cingalee plough on every description of land; but from the references to the reports I have made it will be seen that while the use of improved ploughs is advised, where it is advisable to use them, other desirable methods, besides ploughing, are brought to the notice of the native cultivator, while not the least important work of the Agricultural Instructor is the importation and popularizing of products comparatively unknown to special districts. I am most anxious that greater facilities should be given us for the distribution of seed among the poorer cultivators,—a measure which at this stage of our agricultural reform it is most necessary to favour.

I must not omit to mention that great help and encouragement have been given towards the furtherance of our work outside the School by both Government officials and private gentlemen. Among the former, are the Government Agents of Kurunegala, Ratnapura, and Batticaloa, the Assistant Government Agents of Kegalla and Matara, while among the latter I must specially mention Mr. Clovis de Silva of Moratuwa among a number of our benefactors.

Our School Magazine still flourishes, and the project of issuing Sinhalese leaflets embodying useful agricultural information for the people has been an unqualified success, and will, I feel confident, bear much good fruit. I must acknowledge my indebtedness to the assistant masters, Messrs. Jayawardene, Silva, and Rodrigo, for the willing and efficient help they have rendered me in carrying on the work of the School. Mr. Jayawardene is still our practical instructor, and his self-imposed dairy work has been as creditable as it has been successful.

The crops that have been and are being raised on the School grounds include paddy, Indian corn, arrowroot, dhall, horse-gram, manioc, cumbu, black, gram, lathyrus sylvestris, grasses, fruits, and vegetables. It is contemplated to adopt the method of improving our poor sandy soil by folding cattle on the land next year.

On the whole I am led to believe, when all circumstances are considered, and the difficulties which beset them are (as is seldom the case) fully appreciated, that those concerned in the work of agricultural education, whether within school-walls or in the open field, have good reason to congratulate themselves on the support and encouragement they have received in their work from all classes, and on the fact that their detractors are in a very small minority. I trust, sir, that in spite of the necessarily slow progress of agricultural reform—whether in this country or any other country in the world—Your Excellency will—before the close of your reign in this island—be able to recognise very general and marked traces of the beneficial influence which the School of Agriculture has exercised on the native agriculture of the country.

Mr. J. B. CULL then addressed the meeting. After the lengthy report which had just been read, he need only say a very few words. There were, however, one or two points to which he might refer. The School was established by his predecessor nearly seven years ago, on the abolition of the old Normal School. It began, to a certain extent, in a humble way. Its numbers since then had been increased, though not very appreciably. At the outset of course it met with difficulties—difficulties which he thought were almost inevitable. There was the difficulty as regarded the conservatism in cultivation which prevails in all countries. Husbandmen were very tenacious of old systems and unwilling to embrace new systems. In the second place there was the difficulty—though it might seem paradoxical to say so—of the bountifulness of nature. In the greater part of this island nature responded with so lavish a hand to any call that was made upon her that the husbandman was not inclined to make any effort to increase the productiveness of the soil. At the outset also it, of course, met with some detractors. There were fears as to its permanence and usefulness. Both these fears had proved to him, he was glad to say, and were still proving groundless. Its permanence he thought they might take as assured, and of its usefulness he did not think there could be any doubt judging from the number of applications that he received as Director of Public Instruction, from month to month, from the various Agents in the island for the facilities of agricultural instruction. The number on the list at present was 26. He could see that the area of the usefulness of the school might well be enlarged, and he hoped it might be in his power to do so before long. He felt perfectly sure that if one could only have a successive supply of agricultural teachers to go out to the various schools in the island and energize there,—not only in the schools but amongst the village population,—good results could hardly fail to be produced. In this respect he was very glad to be able to acknowledge with thanks the generosity of

Government in allowing a vote for six new agricultural instructors next year. It seemed to him that the best plan of dealing with these students was to utilize them as itinerating instructors—not confining them to this school or that school, but allotting them to a certain district, say for a couple of harvests or even more, but not for any length of time, and then transferring them to other districts which also required exploiting so to speak. He had spoken of the preliminary difficulties which were encountered, but he thought he could now say, judging from the applications for instructors which had been made to him by the various Agents, that the success of the school was fairly established. He had applications from Kurunegala, from the Government Agent of Ratnapura, from the Assistant Agent of Kegalla, and from two other centres, and that fact witnessed to the usefulness of the instruction which was imparted. The chief object of the instructors hitherto had been the economic cultivation of paddy. There was no doubt from the reports he had received from the Government paddy cultivating areas of the island that the experiments that were conducted had been very successful. At the end of last year he received a long report from the Government Agent of the Eastern Province in which he conclusively showed that, comparing the two systems of cultivation—the improved system as taught by the instructors, and the old system as pursued by the ordinary village cultivators—the yield of the new system was incomparably superior. He thought the attention of the instructors might profitably be drawn to another form of cultivation, that was fruit cultivation. There was no doubt whatever that fruit cultivation so far as Colombo was concerned and the island generally, was more or less rudimentary; very little improvement had been made in that direction. A better growth of oranges, plantains, and mangoes might be obtained, and he had no doubt the Principal would turn his attention to that. One thing he was glad to note was the issue of leaflets by the Principal. These had no doubt been productive of much interest and much good amongst the people. He was informed by the Principal that the issue of leaflets now amounted to something like 6,000 per month. As regarded the dairying operations of the School he had that afternoon visited the farm and cattle buildings where there were about 16 or 18 cows, and the Superintendent of the dairy farm told him that he made a profit of something like 40 or 50 rupees. When one considered how very little was done in the way of dairying, it being almost impossible for one to get a glass of milk when travelling, although cows are swarming round about him, the new departure in the way of dairying seemed to be a great promise. He did not propose to detain them any longer, but he should like to bear this testimony to the work and energy displayed by the Principal during the past year. There was no doubt that whatever practical success especially the School had attained was due to Mr. Driberg's successful tuition. He felt sure that all those who were interested in the welfare of the villagers generally as connected with agricultural operations would coincide in that opinion. (Applause.)

H. E. the GOVERNOR:—The pleasing duty of distributing the prizes is the next item on the

programme and devolves upon me.

The prizes and certificates were then distributed by H. E. as follows:—

SENIORS.—Theoretical Agriculture, Chemistry and Botany, E. M. Johannes; English, Mathematics, and Entomology, E. M. Johannes; Botany and Zoology; H. S. Dias; Practical Agriculture, S. S. Viramuttu. Special Prizes:—Mr. de Soysa's prize (R25) for Practical Chemistry, E. M. Johannes; Mr. Jno. Clovis de Silva's prize, (R10) for Practical Agriculture, S. S. Viramuttu; Mr. J. H. Barber's prize, (books) for Practical Agriculture, J. S. Salgado; Mr. A. M. Chittambalam's prize for Theoretical Agriculture (cheque R10), E. M. Johannes.

JUNIORS.—Theoretical Agriculture, H. B. G. Athapattu; Chemistry, R. Jayasiriwardene; Chemistry, H. B. G. Athapattu; Geology, T. B. Kehelpannala; Mathematics; F. Gunawardna, Botany, K. D. Romial; English, History and Geography, T. B. Kehelpannala; History and Geography, Athapattu; Field Surveying, K. D. Romial. Special Prizes:—W. de Mel's prize (books) for Practical Agriculture, C. M. Abayasekera; Mr. Arnold Dias's Prize (books) for Practical Agriculture, S. Nallasully; Mr. S. T. Muttiah's prize for Field Surveying (R10), K. D. Romial.

Certificates were presented to the following students, who are leaving the College:—S. M. Johannes, H. H. Dias, S. S. Viramuttu, C. H. Perera, D. Amarawickrama and J. S. Salgado.

H. E. the GOVERNOR afterwards said:—Ladies and gentlemen, I am sure you have in common with me listened with profit and satisfaction to the very full report which had been read by the Superintendent of the Agricultural College, and the commentary upon it which we have heard from the Director of Public Instruction. I say for myself that I have listened to that report and these comments with profit, because I find that I have gained by them information which I certainly did not possess before of the object, history and progress of this institution. I have listened to these remarks with great satisfaction because they have put before us a very satisfactory history of the working of the Institution even after making allowance for a little very natural enthusiasm on the part of the Superintendent. It is difficult to exaggerate the importance of an institution of this kind in a country like Ceylon which is almost entirely dependent on the development of its agricultural sources, and I am particularly glad therefore to see so many visitors present to give their encouragement to this particularly interesting and valuable institution. The syllabus that I hold in my hand of the intended work of this College is a very comprehensive one, comprising as it does a large number of theoretical and practical subjects of education, and when this syllabus is augmented, as we have been told it probably will be, by the teaching of more advanced veterinary science, and also possibly by the ingrafting upon it of some technical teaching, I think there will be very few educational institutions in Ceylon which will equal this College in importance and interest. (Hear, hear.) I was particularly interested by those passages in the report of the Superintendent which deal with the results of experiments in the improvement of paddy cultivation. It is pitiful to

hear of the results of the general run of paddy cultivation in this country. One sees an immense amount of time, labour, and patience expended in cultivating those fields, and the result, we are told, is very often of the very poorest description—far behind the result of the paddy cultivation in India or Burma. In certain portions of the colony in which I have ridden about I have made a point of trying to discover from those who were with me, what was the yield of the fields through which we have been passing. I have often seen fields most beautifully cultivated, there being most painstaking arrangements for irrigation, for damming water, for ploughing, and for every other possible item of cultivation, and I have been told that probably the results may be sixfold or fourfold. I have it on the authority of one of our Government Agents that in his province there are many of the fields which do not yield more than fivefold. The work of this institution therefore in promoting the improvement of paddy cultivation is, I suppose, of all its various works, the most important and the most practical. For that reason I am particularly glad to hear of the satisfactory results that have been attained, and I can only hope that by every possible expedient, by the introduction of new forms of cultivation, and by the importation possibly of new kinds of paddy seed, the work of the College will profit the country. There is one other line of agriculture which I think was dwelt upon by the Director of Public Instruction, and in which I am also glad to hear that there has been considerable progress, and that is the improvement of cattle. I believe an immense deal can yet be done in this country in that way and without very much difficulty. Even in the neighbouring country of India, there are breeds of cattle which are far superior to ours, and without going further than that country, I think we can do a great deal by importing good stock. (Applause.) I notice the sun is getting low, and therefore I will not detain you with any further remarks. I would only say that I thank the Superintendent and the students of the College for their kind welcome to me today. I also express my sympathy with them in their work here, and my earnest hope that it will meet with increasing and well-sustained success. (Applause.)

Mr. H. W. GREEN, who was afterwards called upon to address the meeting, said he had hoped a little while ago that his days of speaking at prize-givings were over. It was always rather a pain and a trouble to find anything to say on these occasions when one had been at so many as he had, but this school having been started by him and being his special and favourite eldest child. (Applause.) while he was Director of Public Instruction, he felt it would be ungracious not to say anything. He then expressed his pleasure at learning from Mr. Cull's speech and from the report of the Superintendent that the work was really progressing. He had a very hard time of it indeed when he started the school. Various Government Agents told him that in advising the native cultivator he was trying to teach his grandmother how to suck eggs, and that his grandmother knew much more than he did. What did he know about paddy cultivation? He replied that in going about the world he had used his eyes and thought he knew a little about it; but

he told the Government in starting it that he did so at his own risk, and that if it was a failure he alone was to be condemned. He was glad to learn that it was not a failure, but he should like to see more than had been done. In a country like this we could not get on too fast. Like the English people at home the Sinhalese and Tamils were very conservative, the Sinhalese especially so, in regard to cultivation. The Governor had made a most kindly speech, and had shown, even more than in his speaking, a kindly disposition towards the work of the School, by allowing the grant for the new itinerating agricultural instructors, and he hoped that that would considerably aid in the progress of the work here. Itinerating teachers were most useful here, and the work of private students on leaving the School and going to their own places or the lands of private gentlemen and officials who employed them was also most useful; but the more help that could be got out of Government the better, because all there knew that the ordinary native did think a great deal of men paid by Government. His Excellency had remarked on the absurdly and lamentably low yield of paddy. It was absurd and it was lamentable. He had also remarked on the beautiful cultivation of the fields and irrigation lands. If it were not heresy, might he say that it was beautiful on the outside, that everything except the first step was beautifully done. It was like the house built on sand that we read about in a certain old book. The house might be beautiful, but there was no foundation. The Sinhalese cultivator and the Tamil cultivator in some districts—not in Jaffna and districts where water was scarce, but wherever water was plentiful,—was inclined to begin on the top without the bottom. He forgot that however bountiful Nature might be in giving him rain or tanks or irrigation, he must prepare the soil for the water. He began to prepare the soil with the water on it. He said this method killed the weeds, and if he spoke the truth he would also say that it saved trouble; but he should plough the land when it was dry, turn the whole thing over and leave it to the baking of the sun for two or three months before the water and the beautiful cultivation came on. That was the one sole foundation fault of paddy cultivation in this country. Wherever the experiments taught at that School had been tried honestly—they had not always been honestly tried—it had been found that where the land had been thoroughly turned up and prepared, they had at least double the crop of their neighbours and often more than double. If the people would only work carefully there was no reason why we in Ceylon should not have the Burma yield, which was something like ninetyfold. The climate was all right, everything was all right, but they did not prepare the soil for the working of bountiful Providence. He should be very glad indeed to hear that the dairy farm was going on well, for it was a most important thing. It was very hard indeed to get good milk, and if anything could be done to increase the supply of good milk to the residents here, it would be a great thing. Still more would it be a great thing to improve the breed of cattle by which the ploughing was done. The objection to all their new ploughs was that they were too heavy for the cattle. It was

not really that, but that the plough gripped into the ground which had to be turned over and thus made it heavy. For the new sort of plough they wanted good wholesome strong beasts with a good hump, that could hitch well on to the plough and pull it well. He thought there was a great deal to hope for in the breeding of improved cattle, and he was glad to see that attention was being paid to it. At the same time he pointed out that he thought the difficulty on that point was unnecessarily exaggerated in native newspapers; and really after all perhaps the general improvement of the cattle and above all the preservation of the cattle against the everlasting recurrence of disease and the loss of cattle by murrain, was more a matter for the veterinary department of the College than any other. Many cattle were lost every year by murrain, and how the supply was kept up was a mystery to him.

On Mr. GREEN's having resumed his seat,

H. E. the GOVERNOR said:—In every meeting in Ceylon in which Mr. Ferguson is present the company would be dissatisfied, and the object of the meeting would be incomplete unless Mr. Ferguson addressed the meeting. I must therefore ask Mr. Ferguson to address us.

Mr. A. M. FERGUSON, who was received with applause, then stepped to the front and said that at the invitation of his friend Mr. Drieberg he felt honoured and pleased to come there, and doubly so after the very kind remarks which His Excellency had addressed to him in calling upon him to offer some observations. The meeting and the institution with which it was connected were exceedingly interesting, as they might imagine, to one whose memory went back to a period when education in its most elementary forms was comparatively in its infant stage—when the instruction by which education was gained—a knowledge of reading and writing was in its infancy. Here they had young men receiving a really practical education for the business of life, and going forth into the various parts of the country carrying their knowledge with them and disseminating it wherever they went: to their own farms or to private employment, or still better as agricultural instructors in the service of Government, always imparting knowledge of immense consequence and great value to the people if the people would only receive instruction from them. The Rembrandt-like picture which His Excellency drew of paddy cultivation in this country was, alas too true; and sometimes the idea had been thrown out that the soil was so essentially poor that it could not be improved. He felt greatly relieved that he had been preceded by Mr. Green, who had put the matter very largely in its true light. The experiments showed that the yield of paddy could be doubled, and tripled, and quadrupled even, by careful cultivation; and one of the great lessons which the agricultural instructors would have to impress upon the people was steady, regular, untiring industry. At present there was a great spurt and then a collapse; the Sinhalese would work day and night for a time in order that they might lie by in a state of torpidity for the rest of the year, and the duty should be impressed upon them of regular industry and attention to their land.

As Mr. Green showed there was too much left to be done by water which was an excellent thing in its proper place, but which, as Mr. Drieberg had shown in his report, when it waterlogged the land was sterilizing and beyond that insanitary. There was much that the people could be taught not only in paddy growing but in other branches. The Director of Public Instruction had requested him to deal with the value and importance of horticulture. Humboldt calculated that an acre of well-cultivated plantains would yield as much nutriment as forty acres of wheat, and he need not dwell on the vast possibilities thus presented. Here we had as fine oranges as any in the world, if only justice were done to them, and they were allowed to ripen on the tree. Dr. Bonavia came over here, got some ripe oranges, kept them for a month, took them over to India and they turned out as fine oranges as any in the world. Grafting of oranges and mangoes were almost unknown here, but any person travelling through India would find that a great proportion of the wealth of the people consisted in mango groves, every tree being carefully grafted, and if the Director of this institution could instruct his pupils how to improve horticulture by pruning and grafting, and the pupils carried that knowledge into the villages, the people would have when in a bad year through floods or some cause that could not be helped, the paddy crop failed, something else to fall back upon. (Applause.) Allusion had been made to itinerating students, and that reminded him that in the agricultural papers of which he received many from all parts of the world, he constantly saw most interesting references to itinerating dairies. He hoped the day would come when such a thing as an itinerating dairy would be possible here; when they would have instructors going about with superior cows and superior utensils, and at various centres, instructing the people to make the best use of what was now grossly neglected. More than 50 years ago he lived in Uva in the house of a native headman who had probably 100 cattle, and he could not get a drop of milk. The Sinhalese made very little use of what ought to be a great and wholesome and nutritious article of food—the produce of the dairy, and he hoped there might be an improvement in that respect. With regard to the cattle the duty of the instructors would be to press on the people the lesson that a few good cattle were better than a large number of skeletons such as one so often saw. They allowed the cattle to breed, and they did not ask whether they had sufficient for them in the shape of grass and fodder. That reminded him to suggest to H. E. that it might be profitable in some cases to use the irrigation water in the cultivation of meadow grass for the cattle. When he had the honor of speaking last in connection with this institution he mentioned Java, which was in the same latitude south as Ceylon was north of the equator; and there they had most splendid ponies and not only so but horses of the very finest description. He thought attention might well be directed to the breeding of horses here as well as cattle. (Applause.) In conclusion he said he felt exceedingly glad he had been spared to see such an institution as this in Ceylon and the prospect of a technical institute and other

educational advantages which would enable the people to fight the battle of life with advantages of which their predecessors knew nothing. Thus and similar institutions had all his sympathy; and if through the press or otherwise he could do anything to advance what Mr. Driberg and Mr. Cull and the Educational Department generally had at heart he should only be too glad. (Applause.)

The Hon. A. DE A. SENEVIRATNE afterwards addressed the meeting, stating that he had been asked to make a few remarks from a visitor's point of view. Well, the institution had been doing excellent work, and everybody ought to feel thankful to Government for starting it, to the past Director for carrying it on so nobly, and to the present Director for making up his mind to effect further improvements. The duty lay upon those who had got certificates and were going out into the world to shew that the institution was profitable to the country. It was not by winning prizes there that the thing was to be done, but by going amongst the villagers and inducing them to adopt the improved methods of cultivation. Referring to the observations of Mr. Green he said this place could show grandmothers a better way of sucking eggs. (Laughter and applause.) Everybody could bear testimony to the fact that the cultivation of fruit was very much neglected, but he did not think it would be quite fair to the Sinhalese to say that they entirely ignored the use of milk. He had been in villages where there was hardly a family owning cattle who did not use the milk for family purposes, especially buffalo milk. The ordinary cattle did not produce sufficient milk, but the buffaloes produced plenty. As to improving the breed of cattle he thought they must not forget that there was a very good breed of cattle, for which thanks were due to the late Mr. De Soysa, and he trusted that members of his family would follow up the work of their father and keep up and improve the breed of cattle. He thought they must have heard before of the great work that Mr. De Soysa performed in removing from destitute villages a large number of villagers and supplying them with the means of living and cultivation, and he trusted his successors would follow that example. In conclusion, he said he felt it his duty to say that all felt thankful to His Excellency, Mr. Green and the Principal of the institution. (Applause.)

II. E. the GOVERNOR:—It now remains for me, the programme having been brought to a close, to break up the meeting, which I am sure has been highly agreeable and interesting to us all.

The meeting then separated, the students giving cheers for His Excellency and the other gentlemen as they left the room.

After the ceremony the company adjourned to the playground, where light refreshments were served, and the time was pleasantly passed with music supplied by the band of the 1st Gordon Highlanders.

OCCASIONAL NOTES.

In another column will be found the report read and speeches delivered on prize day. The good feeling displayed by all the speakers from His Excellency the Governor downwards helped to

make the time pass very pleasantly. We greatly missed Mr. George Wall on the occasion when he was to have spoken, but was prevented owing to a sudden call upon country on business. A notable feature in the proceedings was the large number of prizes offered by those interested in the School, and our thanks are due to Messrs J. W. C. de Soysa, Jacob de Mel, S. T. Muttiah, A. M. Chittambalam, J. Clovis de Silva, J. H. Barber, and Mrs. Arnold Dias, for the cheques and books they presented.

We offer our best thanks to Mr. J. P. Williams, seedsman at Henaratgoda, the enormous extent of whose business is little known, for the gift of the following plants to the School:—4 plants each of Malta lemon, Begori lime, Coornul lemon, and Lisbon lime, 6 of *bassia latifolia*, 6 giant loquat, 6 red toon, and 6 saul tree (*shorea robusta*). The last is valuable both for its timber (which is considered only second to teak) as well as for its resinous oil.

"Would it not be a most important service," writes Miss Ormerod, "if you could induce your pupils and other correspondents in connection with your School of Agriculture to note down the habits of your most injurious insect pests, and for you to form these year by year into a report with a figure as well as correct scientific and popular name of the insect? Perhaps you do this already, but if not, you would do immense good if you could bring it about." The fact is we have made an effort to do what Miss Ormerod wisely urges on us, but since we have no opportunity of moving about and collecting specimens of insects where they are pests, we can only depend upon others to send them to us. One or two of our Agricultural Instructors have been good enough to supply us with a few of these specimens, but in order that these may reach us in a condition in which they will be of use for identification, they (the Instructors) would need to be supplied into alcohol, bottles and cases for the purposes. There are some, however, who have an idea that there is no need of seeing, much less of identifying an insect in order to suggest a remedy, and with such people, who should know better, it is difficult to deal with. Will Miss Ormerod's advice have any effect upon them?

The following is a letter from Mr. P. Samaranayaka, Agricultural Instructor, to the Director of Public Instruction:—

Aknimane, 5th September 1891.

Sir,—I beg to submit the annexed results of the 16 acres of paddy land cultivated by me for the "Yala" season 1891 according to the improved system, and a comparison of the same with two of my neighbours' results. 3 acres planted out with seedlings raised from $\frac{3}{4}$ bushel of seed paddy yielded a crop of $79\frac{1}{2}$ bushels. 13 acres were sown broadcast with 19 bushels of four and five months' seed paddy, obtained a crop of 278 bushels, and had an average yield of $21\frac{1}{2}$ bushels per acre. The neighbouring cultivators who cultivated according to their method had obtained 21 bushels from $1\frac{1}{2}$ acres with 3 bushels of seed paddy and $25\frac{1}{2}$ bushels from 2 acres by using 4 bushels of seed paddy. The total yield of the 3 and 13 acres

is valued at R446'87½, and deducting expenditure and grain-tax R205'12½, there is a profit of R241'74½.—I beg to remain, Sir, Your most Obedient Servant,

(Signed) P. SAMARANAYAKA,
Agricultural Instructor.

To J. B. CULL, Esq., Director of Public Instruction, Colombo.

The results of the 16 acres of paddy land cultivated for the Yala 1891 at Akmimana.

	Extent sowed.		How much seed used.	Cost of Cultivation.		Crop.	Bushels per acre.	Amount of sale.		Profit.
	Bu.	R.		c.	Bu.			R.	c.	
<i>Instructor:</i>

Remarks.—Grain Tax R30 is subtracted.

Mr. Samaranyake also states he did not use any kind of manure, and gives further details regarding cost of cultivation as follows:—

	tho	R.	c.
Preliminary works and ploughing			
whole extent of 16 acres	..	27	50
Cross ploughing and clearing dams	..	18	30
Preparing laud for sowing 13 acres	..	16	15
Levelling and planting out 3 acres	..	7	00
Seed paddy 20¼ bushels	..	28	12½
Reaping, threshing, winnowing paddy of 3 acres	..	15	05
Do do do do 13 acres	..	63	00
		175	12½

We are glad to be able to state that some of our benefactors have offered us help in order that we may open out the new block of land granted to the School, and our thanks are due to Mr. J. W. C. de Soysa who has succeeded his most estimable father as a kind supporter of this institution, for a donation of fifty rupees.

Professor Primrose McConnell, the well-known author of the Agricultural Handbook, writing from Oregon, Essex, where he is farming, says:—"The University Commission proposed to abolish the B. Sc. in agriculture at Edinburgh, but I understand that wiser councils prevailed, and it is to be allowed to stand. Nobody knows definitely yet, however, and Wallace (the Professor) is in Egypt at the present time. Both Oxford and Cambridge are proposing to institute a proper curriculum of agricultural teaching, but up to the present time the matter has got no further than the making of propositions and passing of resolutions, with adjournments for further consideration. I am hoping that something definite will be done by both of these Universities during the coming winter. The various County Councils are developing systems of 'extension' lecturing or peripetetic teaching."

The small parcel of lathyrus sylvestris seed which was expected at the School for experi-

ment, arrived from Italy, but we regret to say that the germinating power was very low. It is, however, gratifying to be able to say that we have some specimens of this world-renowned fodder plant at the School. It yet remains to be seen whether cultivation on a large scale will be a success, and whether all the qualities claimed for it will appear in the plant as cultivated in Ceylon. The seeds do not germinate very readily, but when they do, a stem of some length is produced before the appearance of the leaves, which being at first enclosed within two comparatively large stipules, come out in pairs.

Mr. J. P. Manchunayake, now employed in Kwala Lumpur, under the Straits Settlements Government, where he is keeping up his agriculture, has most thoughtfully sent us a parcel of seeds of the fruits commonly cultivated in the country, such as Chinese apple, Malayan breadfruit, pomelo, plum, &c.

S. Mahawalatenne Ratemahatmaya of Atakulan, who has helped us in circulating the agricultural information leaflet, has offered to give a trial to any plants and seeds new to the Island or his district, on his extensive lands.

The School of Agriculture closed for the Christmas vacation on the 31st November. We draw attention to a notification by the Director of Public Instruction that a new batch of students will be admitted next term. The school re-opens on the 16th of January 1892.

INDIGENOUS FOOD PRODUCTS:

CULTIVATED AND WILD.

By W. A. DE SILVA.

Asclepiadaceae.

56. *Hemidesmus Indicus*, Brown.

This plant is known as *Iramusu* in Sinhalese and *Nannari* in Tamil. It is a perennial with a thin woody creeping stem, and small lanceolate leaves of a pale green colour. Along the midribs the leaves have a whitish appearance. This plant is found growing in the warmer regions of the Island both in cultivated and uncultivated places, and comes up with great luxuriance in new chena clearings.

Just inside the epidermis or the outer surface of the roots and stems of this plant a fleshy covering is met with. This substance is of a whitish colour, has a flowery texture and a pleasant though a peculiar taste.

The whole plant is pounded and a congee is made by adding a little rice. This preparation is considered to possess healing properties, and is especially recommended as a purifier of blood. The leaves are sometimes dried and an infusion made which resembles tea in many respects. The infusion has a pleasant taste, but unlike tea contains no tannin. *Hemidesmus* tea is a favourite beverage among some of the natives of the island. The root is much used in medicine, and is often called Indian Sarsaparilla. It is prescribed by native medical practitioners to purify the blood, promote appetite, and to cure skin diseases.

A sherbet is also made from the *Hemidesmus*, and is sold under the name of Nannari sherbet. The plant is said to be largely used as a substitute for Sarsaparilla, and there is some demand for the roots in the London market.

57. *Dregia Volubilis*, Benth.,

is called by the Sinhalese Kiriangua. This plant grows in the warmer parts of the Island, and when found in the vicinity of dwelling-houses generally receives attention. It is a large perennial creeper, much branched, with light green, cordate leaves of rather a hard texture. The leaves of this plant are used as a food in the form of a dry curry, and is much relished, though it possesses a rather bitterish taste. The curry made of *Dregia* is considered to be a very wholesome food, and is given to women after childbirth to increase the secretion of milk. A large creeper of *Dregia* is found growing in the premises of the Hendela Leper Asylum, where it is freely partaken of by the patients and is much relished. The native medical practitioners use this plant as a febrifuge, and it is also said to cure asthma.

Convolvulaceae.

58. *Argyria Populifolia*, Chris. Sin. Giritilla.

This is a perennial creeper with a rather succulent but hardy stem found growing in low jungles and the uncultivated places in various parts of the Island. The leaves are cordate and large in size, with prominent veins, which give a freckled appearance to the leaves which are thick and succulent. The fruits are borne in clusters, and are about the size of small marbles, round and smooth, and green when young, but becoming an orange colour when ripe. The pericarp is fleshy. The young shoots of *A. populifolia* are used in making a dry curry, and the pericarp of the fruit is also made into curries and eaten. There is a slight peculiarity in the taste of the fruits, and hence the curry is not in general favour.

59. *Ipomea Uniflora*,

called *Potupala* in Sinhalese, is a creeper found in uncultivated places. This plant grows abundantly along the hedges of paddy-fields. It is a small perennial creeper with pale, green fleshy leaves of a small size and oval in shape. The leaves of the *I. uniflora* are made into a dry curry and eaten. It is also much relished when fried in oil.

THE CULTIVATION OF THE COCONUT PALM.

Constant and careful watching both by night and day is most necessary on all young coconut estates. On a property of from 80 to 100 acres, fine permanent huts for watchers should be built and fires kept burning before them during the night. One hut in each corner and one in the centre are absolutely necessary. The watchers themselves should make as much noise with their voices and by other means, such as empty kerosine tins which are struck with a stick, to keep off deer, pigs and porcupines, and by day to alarm the parrots which do an incredible amount of mischief and damage. In addition,

the firing of guns by one or two watchers is advisable. The flesh of parrots and wild pigs are, by the way, by no means to be looked down on. The salary of a watcher on a coconut estate in the Eastern Province is generally R7.50 per mensem. This seems little, but it must be remembered that the watcher, though he keeps off marauders, is not above stocking his pantry with Indian corn and manioc.

Under favourable conditions each Indian corn plant will yield from 3 to 5 and sometimes 6 cobs each, and a manioc plant give a return of from 10 to 20 large tubers. It sometimes happens that only one tuber of the latter is found, but when this occurs too frequently it will be found on examination that the rest of the tubers have been priggled, and this can always be detected by the appearance of the broken part. The shooting-man gets about the same pay as the watcher, and generally has something that has fallen to his gun to send to the bungalow, such as deer, ducks, pigeons and jungle fowls.

The enemies of the coconut tree at all stages of its growth are many. When the tree is young, either in the nursery or after being just planted, the villagers will, if they have an opportunity, pull up the plants to sell, to replant them in their own land, or to eat the spongy substance into which the liquid in the coconut becomes transformed. Cattle and buffaloes will destroy the fronds and young shoots, often pulling the plants out of the ground in doing so; while porcupines and pigs will dig up and devour the nuts. Again, coconut beetles will bore into the shoots or stems, and will, if not discovered and killed in time, utterly ruin the trees. Thus the need arises for engaging men or boys to destroy the beetles which are turned out of the orifices in which they imbed themselves, by means of sharp-pointed sticks. It is not uncommon for a boy to bring in 15 or 50 beetles of an evening to the bungalow for inspection and eventual destruction by fire. There are two kinds of beetles which attack the coconut plant: one is the black beetle which commonly attacks the young shoots and soft tissue generally; and the other the red beetle, which bores into the body of the plant and discovers its presence by the fading of the tender leaves and shoots. These latter have to be literally dug out, and the resulting cavity filled up with a mixture of earth and lime. Beetles will attack even trees in full bearing at any stage of their existence. When the trees are in flower they are particularly attractive owing to the scent of the blossoms. Thus it must follow that there is great loss by beetle attack, and endless trouble results, as every plant killed by beetles has to be replaced, and the process of fencing and watering (that is, where the system of supplying is followed) kept up. On many estates, however, the supplying of "failures" is never attended to.

BY HIGHWAYS AND HEDGES.

Drury mentions the fact that many species of *Drosera* (especially *Drosera Peltata*) yield a dye which however is yet unrecognised for any economic uses. The leaves bruised and mixed with salt and applied to the skin are said to

blister it. If mixed with milk they will curdle it. Cattle will not touch them.

Chilanthi arisi or rice consists of the bulbous roots of a sedge, *Cyperus bulbosus*, which are used as food in times of scarcity, and are eaten roasted or boiled. Some dry them in the sun, grind them into meal, and make bread of it, while others stew them in curries and other dishes. This sedge is found growing freely in Delft and the northern part of the island generally. The Chilanthi is sometimes roasted and carried for sale together with gram. It has rather an aromatic and not unpleasant flavour, and is also known as mnsalai pullu. Through the kindness of the Government Agent of the Northern Province some plants and bulbs of this sedge were lately sent to the Colombo School of Agriculture.

The Sinhalese kalanduru (*Cyperus rotundus*) very common as a troublesome weed in cultivated ground also produces tubers which are used medicinally by the natives. This sedge is however distinguished by its broader leaves from *C. Hexastachyus* *C. bulbosus*. Thwaites puts the two down with *C. tenuiflorus*, and *C. Pertensis* as varieties of one and the same plant. Drury refers to *C. Hexastachyus* as very common in India, especially on sandy soils: the tubers being sold in the bazaars and used by perfumers on account of their fragrance. In medicine the bulbs are used as tonic and stimulant, and have been employed in treatment of cholera. In the first state they are given in infusion as a demulcent in fever, and also used to cure dysentery and diarrhoea. Pigs are fond of the root and cattle eat the sedge. *C. Pertensis* also produces aromatic tubers, which are used in India for perfuming the hair.

Some grass seeds were sent last year for trial at the School of Agriculture and were referred to as those of "Lemesuria grass." The official after whom the grass was named, when referred to, kindly supplied its name, viz., *Paspalum Conjugatum*. This is the broad-leaved savannah grass or sour grass of Barbadoes, which, says Mr. William Ferguson, was supposed to be introduced to Ceylon as a useful fodder, by whom he does not say. It is a creeping grass and spreads very rapidly, frequently taking the place of other grasses and killing them, as is proved by the manner it has grown at the School of Agriculture.

The natives of the Ratnapura district seem to make the most of the materials available for mat making. The following are the native names of mat-making materials:—Talkola, polkola, minnwan, potukola, haukoha, hinpan, hewan, okeya, kadmuwan, tmlheriya, indikola, watekdya, hulanpan.

Dorana-tel is an oil extracted from the Dorna tree (*Dipterocarpus glandulosus*) which, says Thwaites, is easily recognised from other dipterocarpi by the glandular pubescence on the under side of its leaves, which is at first pale yellow, then red, and in the old leaves nearly black. The oil which is extracted from the wood as in the case of hora (*D. Zeylanicus*) has a strong

resinous odour, and is used by painters. It is also mixed with the "milk" of kirriwel (*Ichnocarpus frutescens*) to produce a gline which is smeared over a wicker frame fastened to a long pole to capture flies which injure the tender paddy ears.

ROVER.

GENERAL ITEMS.

The Botanist to the Agricultural Department of New South Wales in his report, points out that one of the problems of the western district of the Colony is to conserve the autumn and winter rains for the ensuing summer, since, in an incredibly short space of time, much of the storage water has been lost by evaporation, the result being loss to agriculturists. The opinion of the Botanist, which is also held by Baron von Mueller, is that certain floating aquatic plants will check the evaporation of water during the summer months. In comparing, some fourteen years ago, two ponds, one covered with *Azolla rubra*, a small floating aquatic plant, and the other almost covered with the leaves of *Nymphaea gigantea*, an aquatic plant rooted in the mud, he found that the water in the pond where the *Azolla* was growing kept beautifully cool, and held out during the summer months, while the other was almost dried up. Subsequent observations fully confirmed his conviction that nature really intended these small aquatic plants to prevent the evaporation of water, whether deep or shallow, in warm climates. The fruits of many of these plants abound in farinaceous matter, and are of considerable economic value. The absorption by the roots, which are as fine as hair, from a quarter of an inch to 3 inches long, and the transpiration by their leaves, are exceedingly small in comparison with the beneficial check these plants have on the evaporation of water. Thousands of plants of *Azolla rubra* are now being sent to the different tanks in New South Wales. Of the plants recommended by the Botanist to the department for checking water evaporation from tanks, the following are indigenous to Ceylon: *Trapa bispinosa*, *Lemna minor* and *L. polyrhiza*, and *Azolla pinnata*.

Jethro Tull, who is known as the father of modern husbandry, and who taught the farmer the value of drill culture as well as that deep ploughing and pulverisation of the soil render a much smaller application of fertilisers necessary, was born at Basildon in Berkshire in 1674. He was educated at St. John's, Oxford, was called to the bar, became a benchet, and after being wedded to music for a time, made the "grand tour" previous to his entering public life, but on his return circumstances changed his purpose and he devoted himself to agriculture. "His deeds, his triumphs," said Dr. Johnson of Tull, "were of the peaceful kind, with which the world in general is little enamoured; but their results were momentous to his native land." Sir John Lauges said of him "he was a century in advance of his time." Jethro Tull died in 1741.

The sedimentary deposits taken from ponds and lakes, says a writer to the *North British Agriculturist*, forms a very useful dressing if spread alone over a barren part of a field, but it would be more desirable to have it mixed with lime before application. The lime hastens the decomposition of the organic matter in the leaves and other *debris* of vegetable forms, and materially adds to the usefulness of the dressing. This stuff may also be profitably used in covering dung heaps, as it will serve not only to waterproof the dung heap, but also to absorb any ammonia that might otherwise escape from the decomposing dung. This is seasonable advise in view of the dredging of the Colombo lake.

Among the enemies of the paddy plant is the caterpillar of a small moth named by Mr. Wood-Mason the *Paraponyx oryzae*. This caterpillar is to be about a quarter of an inch long, and in this condition to live a purely aquatic life, breathing by means of tracheal gills, and to change to chrysalis in a cocoon of whitish silk. Miss Ormerod suggests throwing lime into the water of paddy-fields to destroy the pest.

Another suggestion put forward by Miss Ormerod is that sand, ashes or dry earth sprinkled with paraffin in the proportion of one quart to

a bushel of the dry material should be used (without fear of injuring the young growing parts) to sprinkle about the tops of coconut palms so as to keep off grubs and caterpillars. This of course would only be practicable where men are sent up the trees to pluck the nuts, on which occasions they should be made to carry a supply of the paraffinated substance in a bag slung across their shoulders.

Ground-nut oil is expressed in Formosa something after the fashion in which coconut oil is expressed by the natives. One hundredweight of nuts gives about 25 pounds of oil, worth 30 shillings. The oil, which is in great demand, is used as an article of food and for lighting purposes. The leaves and stalks of the plant form a nutritious cattle food and a good green manure. Mr. T. P. Manchanayake, one of our old boys now at Kwala Lumpur, where he is successfully cultivating ground-nuts, tomatoes, potatoes, &c., writes that ground-nut is found cultivated in almost every garden, and sends us an interesting and detailed account of its cultivation. Each plant bears from 20 to 40 pods or more. The seeds are eaten fried as well as boiled, and are also curried and eaten with rice. The oil, referred to above, is known as *Muja Ratchan* among the Malays.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. XI.

COLOMBO, FEBRUARY 1ST, 1892.

[No. 8.]

COLONIZATION OF LANDS CONNECTED WITH RESTORED IRRIGATION WORKS.

HERE is a paper published once a fortnight at Jaffna, called "The Hindu Organ," and in a number of this paper which reached us some time ago we saw notice of a colonization scheme which

Mr. Ievers, Government Agent of the North-Central Province was said to have formulated and which received favourable appreciation. We applied to the Colonial Secretary's Office for a copy of Mr. Ievers' scheme, but nothing was known of it there. Application to the publishers of the "Hindu Organ" was then made, and the result is that we have been courteously furnished with a copy of the issue of October 14th of this year, in which appears Mr. Ievers' letter, dated October 31st, 1890, (?) which will be found on page 526. It will be seen that Mr. Ievers' wrote in response to queries from an influential member of the Tamil community at Jaffna, and if the date at the top of the communication is correct it seems strange that the recipient of information so important should not have made it public until it was a year old. The next point which seems to require explanation is the expression of the editor's belief that Mr. Ievers' scheme had been sanctioned by Government. Were this really the case, we think some public indication of the fact would have been made. But perhaps this and much more of a like nature is awaiting the decision of the Secretary of State on the policy which Sir Arthur Havelock is understood to have pressed on His Lordship for adoption. That policy, we know, from His Excellency's utterances, involves the abolition of the paddy tithes (which are in a vast proportion of cases the commutation of feudal services), while the import duties on grain are retained. We need not repeat our well-known conviction that even if any Government ventured to try the experiment (which Mr. Potter, to his lasting disgrace, has favoured) the duties on Indian grain, which would then become directly hostile to our poor fellow-subjects across the strait, would not survive a year. And if the

local tithes are abolished, where is the money to be found for a continuance of the irrigation policy which the home Government specially favours? How are liberal schemes, such as Lord Knutsford suggested with reference to lands "under" Kantalay tank; and how are still more liberal colonization schemes such as the enterprising and practical Government Agent of the North-Central Province has formulated to be carried out, how, above all, is there the slightest chance of the irrigation regions being effectually opened up for settlement and cultivation by the agency of the railway, if we sacrifice the revenue of a million of rupees from local tithes and the more than two millions of import duties on grain which would inevitably follow? The substitution of a land tax would be a Rehoboam-like policy which the goiyas, who all possess uplands cultivated with fruits, roots, and vegetables, would be the first to groan under and resent, perhaps after the fashion of the last argument which "dumb driven" cattle resort to.

One thing seems certain, that the natives of Ceylon (the Moormen, and, perhaps some Tamils excepted) are more immobile, less courageous and less enterprising even than the Hindos of the opposite Continent, where some districts, like Bengal, suffer from population unnaturally congested, while vast expanses of waste land wait, as they have waited for thirty centuries, the axe of the forest clearer and the hoe and plough of the tiller of the soil. It is difficult for us, with our British notions of enterprise and self-dependence, to regard with patience and treat with pitiful forbearance people who, when Government have provided irrigation water, which, with land, low and high, they offer on terms which ought to be easy to men ordinarily industrious, insist that Government must go further and provide them with money capital and seed for cultivation and also with food until the land cultivated commences to give full returns. But it is the necessity of Government's adapting itself to oriental exigencies and adopting a policy so absolutely paternal and even maternal ("Your honour is my father and my mother") which Mr. Ievers recognizes in his elaborate scheme. We really hope the Government will—taking all the risk of loss from insalubrity of climate and failure of colonists to fulfil their obligations—authorize Mr. Ievers to try on a moderate scale the experiment of the success of which, granted normal seasons, he seems so confident. A vote of some £10,000 or so would be well bestowed in testing the success of the ultra oriental and paternal policy recommended. We are, however, beyond measure surprised at the different results, in the shape of crop which Mr. Ievers anticipates from three different products, all grown in virgin soil. Why should rice yield, even when irrigated only 30-fold,—that is 30 bushels in return for one bushel sown,—while kuakkan and gingelli return from 300- to 450-fold? If Mr. Green's statement that over 500-fold had been obtained from a piece of rice land connected with

the Agricultural College, was received with natural scepticism, are we to be expected to believe that from the rich virgin lands of the North-Central Province tank regions, only 30-fold can be expected, even with ordinary cultivation! If so we are inclined to throw up the sponge as regards rice cultivation in Ceylon, and to plead for railway extension northwards, not to aid Ceylon rice growers in a competition so hopeless, but, by means of connection with the Indian railway system, to facilitate the introduction of the cheap and plentiful food grains of India. Kurakkan is reckoned an inferior food to rice, while gingeli, although an interesting and valuable crop, is, like crops of all oil-yielding seeds, especially exhaustive of the soil. It is but poor comfort, therefore, to learn that from virgin soil 450 fold of these "dry" crops can be obtained, if the maximum or even the average we can hope for from the same virgin soil even when irrigated is for one bushel of paddy sown, 30-fold in paddy or 15 bushels when husked and converted into rice. It is difficult to see how native-grown rice can compete with Indian, even with means of communication by the Pamban-Mannar route such as they are. But if once unbroken railway communication between India and Ceylon, via Mannar, is established, it is difficult to see how the local cultivation can pay, except for consumption close to where it is grown, in isolated places remote from roads and railways and central markets.

On a non-political question like this, or which, if political, has reference only to the abstract doctrine of political economy, Government, we feel sure, would not object to Mr. Ievers or any other Civil Servant giving his views to the public through "the papers." In any case we should be glad if he or any other correspondent qualified for the task, by experience and observation, will deal with our difficulties. We can understand a 30-fold return of paddy paying the cultivator at present; but if the introduction of rice from India and its competition with that locally-grown are facilitated by railways in addition to the steamers and sailing vessels employed at present, can the local product hold its own? Be it noted that vast quantities of rice are produced in the alluvials of Tinnevely, Madura, Tanjore and Trichinopoly, within a short distance from Ceylon, so that the cost of railway carriage to the northern portions of our island, at least, is not likely to be great.

CONTROL OF BUFFALOES.—Under this heading an order in Council has been issued by the Government of Perak which seems to show that buffaloes in that State must constitute a danger as well as a nuisance:—

Whereas it is expedient to provide for the more efficient control of buffaloes throughout the State, it is hereby enacted as follows:—1. No buffalo shall be led or driven along any road, path, or track unless controlled by a nose-ring and rope in the hands of the driver. 2. Every buffalo shall have affixed to its horns a guard of hard wood of not less than 1½ inches in thickness, which shall not be more than 1 inch below the tips of the horns, or else the horns must be cut down as near the quick as possible. 3. Every savage buffalo (kerbau heukin) must be destroyed, and the owner will be responsible for any damage done by failure to obey this Order. 4. Every buffalo which shall, after the date of this Order, be found without the means of control herein provided shall be liable to be impounded or shot. 5. Every owner or driver of a buffalo who shall be convicted of non-compliance with any part of this Order shall be liable to a fine not exceeding \$50 or, in the alternative, to a term of simple imprisonment not exceeding three months. Exception.—Nothing in this Order in Council shall apply to any buffalo calf not being more than half grown.

COLONIZATION UNDER RESTORED IRRIGATION WORKS.

We ["Hindu Organ"] publish below at the request of a gentleman in Jaffna who takes a warm interest in the welfare of his countrymen, the report of Mr. Ievers, the energetic, intelligent, and public-spirited Government Agent of the North-Central Province, on the Colonization of Kalawewa. We understand that the scheme propounded in the report has been sanctioned by Government. The Report speaks for itself, and we commend it to the special attention of our readers.

Anuradhapura Kachcheri, 31st October, 1890.

Sir,—I have the honor to submit my replies to your queries on the above subject.

2. It is a matter which has engaged my attention for several years and in which I take the greatest interest. In 1886 (when 2nd Assistant to the Colonial Secretary) I submitted a Memorandum based on the example of the action of the Dutch regarding the transfer of persons from the congested districts to those where land and water were available. I again mentioned the matter in my administration report for 1886, (page 1st A part I.)

3. In reply to the query in the 1st paragraph regarding capitalists or "people in poor circumstances," my recommendation had regard to the latter. In case of "capitalists" I consider that an application from a pioneer capitalist should be dealt with on its merits and by special agreement with Government. Such agreement ought to allow favourable terms to the capitalist who takes the risk. If his experiment is found to be successful I would recommend that subsequent speculators should only obtain the land under the conditions now allowed by Sir Henry Ward's minute. It would be a great matter to secure a nucleus of cultivation independent of Government aid as it would encourage other settlers and I regret that former offers for the taking up of land under Kalawewa were not favourably received. In the case of capitalists I expect that the owner would import his labour from some other districts. In the case of the lands sold at Anuradhapura the purchasers have imported Tamil labourers chiefly and settled them on the higher portions of the lands where they have made flourishing gardens of coconuts and plantains, yams &c.

4. In reply to the query in the 3rd paragraph of your letter I submit what I consider is a fair estimate of the cost of colonization by persons who, if not absolutely paupers, have not the means of subsistence in a strange country for such time as may allow of their being fed by their own labour. I consider such colonists in the light of labourers taken on and supported by Government as landlord, in the same manner as might be done by a planter, only on more favourable terms to the labourer. The Government Agent may be taken to be the Manager of the property.

5. I now proceed to discuss the cost of bringing a given block of land into cultivation under the proposed conditions.

6. Ten men working all day will clear an acre of undergrowth. The same number working for two days will fell the trees. Therefore 30 men will fell an acre in one day or 30 acres in the month. I take this extent as a basis of cultivation. This 30 acres I would, to commence with, divide into 15 acres of high land and 15 acres of low land. I allow 15 acres of high land in order to produce an early crop and render the cultivator independent of aid.

7. Operations of housing the colony should commence in the beginning of May and the felling and clearing should proceed in May-June. Burning takes place in the end of August and after second burning and fencing, sowing begins with the September-October rains. Kurakkan should be sown on the high land and paddy what is called a paddy chena (Vi-bena) or the irrigable land. These seeds grow from rainfall but if the Vi-bena can be irrigated when half grown it will be all the more successful. Kurakkan is reaped in January and Vi-bena in February.

As to the expenditure—The cultivators must be supported from May to January, say eight months; seed must be supplied for 30 acres.

SEED-KURAKKAN for 15 acres at 3 seers to the acre=45 seers; value at 4 cents per seer=R1-80.

SEED-PADY for 15 acres = 15 bushels which at R1-00 per bushel, R15-00.

Even if paddy be slightly higher in price the expenditure will be under R20-00.

9.—As to the return which the cultivators might reasonably expect:—

In VI-HENA the average yield is 30 fold.

In Kurakkan it is at least 300 fold in forest land such as we are dealing with. Consequently the average yield of 15 acres of Vi-hena = 450 bushels of paddy or 225 of rice and of Kurakkan the yield would be also 450 bushels. This is the usual yield, enormous as it may seem.

10.—After the Maha harvest a crop of gingeli should be raised for yala. This is a most profitable crop. It is sown at the end of March but only on high ground and could be sown on the 15 acres from which the Kurakkan was reaped. One seer of gingeli (at 8 cents per seer) will sow an acre. Therefore the 15 acres could be sown at a cost of R1-20. Gingeli gives a return of from 300 to 450 fold: on forest land the latter might be expected. The yield of the 15 acres may be taken to be reasonably 195 bushels. Gingeli sells from R2-00 to R3-00 per bushel, thus giving a return of from R390-00 to R585-50 according to the price.

11. Presuming that water is available for the other 15 acres of low land, hineti paddy should be sown in April for Yala harvest while the highland is in gingeli. Cost of seed for 15 acres of hineti=R15-00.

Therefore the total expenditure for seed would be:—say R33-00.

Maha, Vihona	R15 00
do Kurakkan	1 80
Yala, gingeli	1 20
do Hineti	15 00
	R33 00

12. This covers the time from the clearing in the middle of May in one year to the reaping of gingeli in the end of June in the next year. I assume that the cultivators require support up to the reaping of the Kurakkan in January, i.e., for eight months. I assume also that for each "able bodied labourer" there is a family of a man, a woman and two children. I consider that two bushels of rice a month and R3 for sundries, dryfish, currystuffs, cloth, &c., is an ample allowance=R10. 30 families at R10=R30 and this for eight months gives a total of R2,400. If to this be added the value of the seed the total=R2,433—say R2,500.

13. But it must be noted that I have only calculated for one month's clearing in May-June. There is no reason to prevent the cultivators from clearing 300 acres of irrigable land in June-July. Consequently we would have under crop 45 acres of mud land and 15 acres of high land. For this additional 30 acres we may allow R30-00 for seed for maha, and adding this to the previous total we have an expenditure of R250-00 to bring into cultivation 45 acres of mud land. The 15 acres of high land might be planted up for gardens or used as a site for a village, &c.

14. I am quite prepared to undertake operations under these conditions of expenditure if they are approved by Government. But I must point out that the persons whom I desire to have as colonists must not be selected from a town population. I wish to have peasants who already have a knowledge of cultivation and I would prefer Sinhalese though I have no objection to Tamils. I could carefully separate the different races; and this could easily be done. I have at present both Sinhalese and Mubammadans cultivating under Kalawewa.

15. I would undertake to supply the rice and allow a credit of R3 to each family at a store which I would establish for the purpose and I would make no money by the cultivator.

16. In the foregoing observations I have chiefly

had in view the case of Kalawewa where I think a colony of the nature indicated could be placed. It would be necessary to house the people in an elevated position until they became acclimatized; and the services of one of the medical officers should be available. Native medical treatment is useless for malarial fever. If it were an unhealthy season in the commencement the experiment would run a great risk of failure and of becoming another Lemesurigama, which I would desire to avoid. I consider the only serious objection to my scheme is the possibility of sickness and mortality frightening away the cultivators. This I could not guard against, though I would take every precaution that experience affords.

The expenditure for houses in the commencement would be nil as timber is available and straw could be procured free from the Yoča Ela villages; while I presume Government would lend axes and machetes for the first year.

17. I would allow no borrowing from usurers and I see no need for any under the conditions of my scheme. If it were publicly known (as I would take care it should be) that the Gansabhawa courts would unfavourably regard any action for money or paddy lent during two years from the start of the colony there would be no borrowing or lending. This would be I am sure the case in this Province at least. As a rule the peasantry of the North-Central Province are not in debt or in the power of usurers. Many persons to my knowledge denied from hearing cases judicially lend seed paddy and money without claim for interest. But even where such claim is made by Moors, Tamils, Afghans and others, it does not appear that the people are to any great extent indebted. I could not allow the land to be given in any Province as security in case of borrowing. It should be set forth under the condition that until the land was finally paid for, it remained the property of the Crown, the occupier being merely a tenant with the Crown as landlord.

18. As to the repayment it may be observed that each man's liability would amount to R80-00 for subsistence and R2-25 for seed paddy=R82-25. I presume the latter would be given free. R80-00 is not a very heavy item of debt, and I recommend that it be recovered in the fifth and subsequent years of occupation by sale (under the original conditions) of 1/4 of the crop; any balance of proceeds above the amount due might be refunded to the cultivator.

19. Persons who desire to accept the liberal terms proposed in the Government Agent's recommendations without subsistence might, of course be granted small lots of one or two acres, apart from the block taken up by what I term "the colony."

20. I think I have replied to all the queries under reference and I have only to add further that if Government desires the experiment of colonization to be made either under the conditions proposed by me or any other that may be determined on, I shall spare no efforts to make it a success.—I am, &c.,

(Signed) R. W. IVERS, Govt. Agent.

A RELIABLE INSECTICIDE.—Mr. W. B. Gardner, of Fort Meade, kindly furnishes the following results:—Four pounds of salt dissolved in twelve quarts of water, then add thirty-two pounds of finely sifted sulphur; have the sulphur well stirred. Then take thirty-two pounds of green rock potash, breaking any hard lumps, put in an iron vessel, add to the potash four quarts of water and let it stand say three minutes, then pour the potash into the sulphur. The mixture will boil with great violence. As soon as it is cold, put into a fifty gallon barrel and fill with water. Four quarts of this solution in fifty gallons of water is said to be sure death to the red spider. Two quarts to the barrel is strong enough for rust mite. It will not hurt the tenderness bud or leaf and can be kept for months. The residuum should not, when properly prepared, exceed one-half pint.—Florida Agriculturist, Nov. 4th.

DRUGS FROM THE GERMAN COLONIES.

The *Pharmaceutische Zeitung* publishes the first of what promises to be a series of exceedingly interesting articles on the progress which has already been made in the cultivation of drugs and other Colonial produce in the German colonies, and on the outlook for the further successful propagation of such articles. Much of the information has been supplied by the Ost Afrikanische Gesellschaft, which is the equivalent of our own British East Africa Company, and the territories of which adjoin the country under British influence on the African East Coast. Particulars have also been given by Dr. Hindorf, who has been acting for some time as the German expert in matters of produce-growing in East Africa, but who has had to resign on account of failing health, and is now in Germany.

TRADE INCREASING.

The unfavourable reaction upon the trade of German East Africa caused by the recent disturbances in the interior has been partly allayed; the German trading establishments in Tanga, Pangana, Bagamoyo, Dar-es-Salaam, Kilwa, and Lindi, are again receiving a considerable amount of trade from the interior, and it is expected that at the end of this year the exports from German East Africa will show a very large increase. This, of course, it should be understood is the official view of the German company, and it is permissible to assume that it is to some extent at least exaggerated. Whatever increase may occur in the exports from German East Africa will in the first place benefit British India trade, as Bombay remains, as it has long been, the chief outlet for all goods from the East African Coast. In fact, the German company in their last report, just published, lay stress upon this fact themselves, and appear to acknowledge that they can only advance the benefit of their territories by increasing the facilities of communication with Bombay. The principal plantation in German East Africa is that at Lewa, where the German East African Plantation Company are growing tobacco. Lewa has a good soil and a sufficiency of running water, which secures the necessary amount of moisture all the year round.

TOBACCO AND VANILLA.

The first crop of regularly harvested tobacco from this plantation will be placed on the market this year. It will be large enough to give a fair test of the capabilities of this plantation. Another plantation company owns a similar tobacco-plantation at Amboni, situated about one hour from Tanga. Amboni is a much-frequented market place and very favourably situated. An area of 42 acres has already been cleared here and is mostly under crops. The harvest prospects are described as exceedingly satisfactory. Quite close to Tanga, Mr. St. Paul Illaire has commenced a vanilla plantation. The possibility of the successful cultivation of vanilla in a climate such as East Africa is shown by the excellent results which have been obtained in the Island of Réunion. In German East Africa itself, at the French mission in Bagamoyo, vanilla has already been produced of which two shipments have thus far been sent to Europe. These two shipments, however, have not been sufficient to indicate with certainty the prospects of success of this exceedingly sensitive crop. The beans of the first shipment are described as being of excellent aroma, but too small in size; those of the second, as having been subburnt and deficient in aroma. It is hoped that better results will be obtained in more sheltered positions.

The requirements for a successful propagation of this plant are principally a constant, hot temperature, and the existence of abundant shade.

COTTON, AND BOTANIC GARDENS.

There is a cotton-plantation at Kikorwe, opposite Pangau, which is the property of the German East African Company; it had to be abandoned when the late disturbances broke out, but has now been taken up again and considerably enlarged. It is under the management of an experienced Mexican planter, who holds out expectations of a fine first crop in the near future. If this first effort is successful, special attention

will be paid to the propagation of various kinds of cotton in the colony, with the view of determining which is most suitable to the soil. It will be necessary to make the cotton-crop in the first place one for cultivation by the natives rather than by European settlers. The French mission in Bagamoyo are also growing this useful plant. The German Government have given a considerable sum of money for the establishment of an experimental garden near the governor's house in Dar-es-Salaam. Governor von Soden is said to take quite an exceptional interest in the growth of economic products. But the principal plantation of all is that of Derema, which was established in August of last year by Dr. Hindorf, and upon which the highest expectations of success are placed. It is situated at an average altitude of 3,200 feet; the soil is rich in humus and possesses the physical qualities of a good loam soil. The plantation has been established on a clearing in the virgin forest, and possesses an abundance of running water, which at the same time provides the power for working all the necessary machinery. There are about 280 natives in constant occupation on this estate. The principal cultures here consist of

TEA, COFFEE, AND COCOA.

Tea is to be cultivated on the highest part of the plantation, as the plants are believed to obtain a finer aroma there than in lower soil, and as, moreover, they are the hardiest of any cultivated. The seed for these tea-plants has been obtained from Ceylon, and consists of China as well as Assam varieties. The authorities do not appear to be very sanguine as to the success of tea-cultivation upon their plantations especially as they work at greater cost than the Ceylon planters. The coffee-seed has been obtained from Sumatra, where the coffee is less subject to attacks of the *Hemiteia vastatrix* than in Ceylon.* The coffee-plantations are next in altitude to the tea-plantations. The first crop cannot be expected until after four years. Coffee-growing in the present condition of the market could hardly fail to be satisfactory from a financial point of view, but it is doubtful whether the same favourable conditions will prevail later. The planting of cocoa has given rise to a great deal of trouble, as it was found that the seeds had lost their vitality upon arrival. Experiments have been made to import the cocoa-beans in cases between layers of powdered charcoal slightly pressed, and also to import seedlings in Wardian cases. The latter method has proved the more successful, although it is exceedingly expensive. Cocoa seed has also been obtained from Ceylon and much is expected from this cultivation, as the demand for the article is said to be greatly on the increase, and less labour is required for this crop than for coffee. This list exhausts the number of staple products. Among the articles which it is intended to cultivate in the first place only in an experimental way is

CINCHONA,

for which a small garden is now being laid out; but although it is intended to raise a few hundred trees, there is no idea at present of endeavouring to enter into serious competition upon the already overcrowded markets. A rather experimental cultivation is india-rubber. The plants of the *Hevea Brasiliensis*, which yields the so-called Pará rubber, as well as of *Manihot Glazovii*, from which the Ceara rubber is obtained, are now being raised. The rubber hitherto exported from East Africa, which last year shipped about 200 tons, is exclusively produced by the wild *Landolphia* varieties; it realises a good price in the wholesale market, and is superior to the West African rubber by reason of its less pronounced odour. But quite lately there has been a great deal of complaint of the increase of adulteration in this product. By Government order, however, issued last year, the trade in evidently adulterated rubber has been prohibited under heavy penalties.

FRUIT, SPICES, AND DRUGS.

Fruit-plantations are also being established, though,

* As coffee abounds in the central African forests, where leaf disease has never appeared, it was very great mistake to send to Sumatra, where the disease certainly exists, for seed.—Ed, T. 4.

if successful, it is not intended to enter into competition upon the European market, but rather to export to Aden for the use of ships passing that port. As soon as time permits, experiments are likely to be made in the cultivation of spices, especially cloves, nutmegs, and pepper (the latter near the coast region), as well as with gambier. The oil-palm does not seem to take kindly to the soil of German East Africa, though, if it should be found that its cultivation is possible there, the erection of suitable modern oil-mills will become a matter of interest. The plant yielding the oil of commerce (*Jateorrhiza calumba*) occurs only sporadically in German East Africa, and as the demand for it is subject to great fluctuations, and is inconsiderable at the best, its propagation does not hold out any inducements. Tamarind trees do occur, but hitherto their fruit has not been gathered for export purposes. Aracnuts have been exported from Tanga and Pangani in small quantities only, and beeswax has, up to the present, been scarcely a commercial article. Among other articles of vegetable origin, copal takes the first place; it is traded in excellent quality, especially in Kilwa and Lindi. Gum arabic occurs in the various kinds, but mostly of very inferior quality, in the Ausha region of the Kilimanjaro mountain. Two bales have recently been received in Germany from the colony, but they show an altogether insoluble gum, the viscosity of which was such that one part of gum to three parts of water produced a jelly-like mass. On the other hand, a sample received from the Ausha district showed an almost soluble drug. There is, therefore, some hope that a suitable gum may be obtained as the result of closer investigation. The main difficulty in the way of successful plantation in German East Africa is the one of cheap labour. Hence only the cultivation of high-priced articles holds out hopes of success. The system of forced cultures (which, for instance, still obtains to some extent in the Dutch colonies) has been frequently recommended as suitable for the production of large staple articles; but the trouble is that it is impossible to force the natives by means of fines, as they possess nothing, whereas physical force could hardly be employed. Some time ago an attempt was made to place a tax upon palm-trees, but its only result was that the natives partly cut down their trees, and one and all refused to extend their plantations. Attempts have been made to induce the natives to cultivate sesame-seed* to a greater extent than they do now by giving them free supplies of seed, but these have not been very successful.—*Chemist and Druggist.*

BRITISH NORTH BORNEO DEVELOPMENT CORPORATION, LIMITED.

A company under the above title has been registered with a capital of £300,000 in 500 founders' and 200,000 ordinary shares of £1 each respectively. The objects of the company are the acquisition of lands, timber, mines, furnaces, factories, businesses, or other real or personal property whatsoever, situate in the island of Borneo or elsewhere, and, with a view thereto, to carry into effect two agreements, the first expressed to be made between the British North Borneo Company of the one part and this company of the other part; the second, made Sept. 21st, 1891, between J. W. Colmer of the one part and J. G. T. Hassell, on behalf of this company, of the other part; to navigate and carry on trade along the river of Borneo or elsewhere, and to develop the resources of and turn to account the lands, holdings, and rights for the time being of the company, in such manner as the company may think fit, in particular by clearing, reclaiming from the sea, draining, irrigating, fencing, planting, building upon, farming, mining, &c.; also as miners and mottors, engineers, merchants, bankers, exporters, and importers, &c. The first subscribers, who take one share each, are:—Lord Waterpark, Dove-ridge, Derby; W. P. Pryer, 11, Harrington Road, L.W.; Sir R. S. Meade, 65, Queen's Gate, S.W.; A. W. Jarvis,

M.P., 120, Mount Street, W.; W. G. Brodie, Elm-hourne, Upper Tooting; C. Ince, 102, Alexandra Road, South Hampstead; and J. A. Godge, 14, Abbeville, Road South, Clapham Park. There shall not be less than three nor more than nine directors. The first are the Right Hon. Lord Waterpark, W. G. Brodie, A. W. Jarvis, M.P., Rear-Admiral R. C. Mayo, C.B., M.P., and General Sir Richard Meade, K.C.S.I., C.I.E. Qualification, £300. Remuneration: Chairman, £400; ordinary directors, £200 per annum each, with an additional 10 per cent. on the net profits of the company after payment of 15 per cent. dividend, such latter remuneration to be divisible.—*Il. and C. Mail.*

HORSE-POWER IN LIEU OF BULLOCK-POWER IN INDIAN AGRICULTURE, &c.

We copy from the *Times of India* a paper advocating the supersession of bullocks and buffaloes by horses and especially mares in agricultural operations. If there is any force in the arguments used as regards India, they apply even more strongly to Ceylon, where the great difficulty in the use of improved ploughs and other agricultural implements, is the small size and weakness of the native bullock. The remedy usually proposed is the use of the larger and stronger Indian cattle, but the first cost of such animals is high and the expense of their upkeep is in proportion. If we had an abundant supply of country-bred horses (and surely horses can be bred in Ceylon) we should not have proposals made to use bullock power even for street tramways. As civilization advances so will the use of meat as food in Ceylon; and it goes without saying that the beef from animals which have worked hard for many years must be far inferior to that of cattle bred specially for milk-giving, manure and the butcher. One great difficulty, no doubt, here, even more than in India, would be to get the cultivators to manage horses. As regards the Sinhalese, it is the rarest possible thing to find a Sinhalese horsekeeper. But this may be due mainly to the fact that the position of a horsekeeper is socially low, just as, in the eyes of the Sinhalese, is that of an ordinary cooly. All agricultural work, however, is deemed honourable, and it does not seem doubtful that in time Sinhalese would adapt themselves to the care and employment of the horse in their farming operations. An experiment might be tried in the grounds attached to the Agricultural College. Mr. Hallon mentions what are rarely seen or mentioned in Ceylon—mules. We have never heard of one of these hybrids being bred in Ceylon, and it is surely curious that while mules were employed in all the carrying work of plantations in the West Indies, they have never been so employed in this island. The bullock has been always our stand-by in Ceylon.

The question is whether at least a partial change might not be advantageously made by the use of the horse?

NOTES FROM OUR LONDON LETTER.

PALAIS INDIEN COMPANY AND MR. LOUGH—TEAS IN LEAD PACKETS—THE ANDES EXPEDITION—CELLULOSE OF COCONUT.

LONDON, Dec. 4

A mail or two back my letter referred to the seemingly extraordinary course pursued by Mr. Lough at the meeting of the *Palais Indien* Company, by which he seemed to endorse the desire of some of the shareholders that the sales of tea by that company should be confined entirely to the teas of Indian growth. It seemed to me that support given by Mr. Lough to such proposals was quite inconsistent with the obligation he had incurred in accepting the position of your Agent

* Gingeli.—*En. T. A.*

for Ceylon teas in Paris. In accordance with the intention expressed to you no time was lost by me in calling the attention of the Ceylon Association in London to the subject, and the Tea Committee of that body held a meeting to discuss and consider the matter. As the result, Mr. Lough was asked to explain, and in reply he stated that the wishes expressed to the meeting which he had supported referred in no way to Ceylon tea, but only to those of Chinese growth or character.

However, the reference to the *Palais Indien* Company did not end here. We suppose that, owing the position Mr. Lough was placed in by his very enigmatical utterances, the directors of that company deemed it desirable to approach the Tea Committee of the Ceylon Association in London with a proposal that there should be a fusion of interests, and that steps should be considered whereby the sale of Indian and Ceylon teas, in their present shops in Paris should proceed simultaneously and without establishing competition between the two varieties. A letter to this effect is to be considered by a specially appointed Sub-Committee consisting of Messrs. Rutherford, Thomas Dickson; J. L. Shand, and Whittall, though it is doubtful if the latter will be able to serve, he being, unfortunately, ill with influenza. This Sub-Committee was to have its first interview with the *Palais Indien* representatives yesterday afternoon, and nothing has as yet transpired of what passed at the interview.

With this you will receive a copy of the prospectus of the company now negotiating the above stated matter. You will see that the articles of association under which this company was registered do not in any way limit the sales of tea to any particular variety, though no doubt the real object was to press into prominence the Indian teas in which the promoters were then chiefly interested. Still all tastes of the Parisians must be consulted, and some palates might prefer Indian, others Ceylon, and others again China. So to impart a taste for tea-drinking, every individual predilection must be gratified. It is dependent upon what is the primary object of the company, whether to foster a taste for tea-drinking in France, leaving it to time to establish preference for particular varieties, or whether it was simply and solely to bring Indian teas into a selfish prominence before the field could be occupied by others.

It was recently mentioned to me by an acquaintance that he had seen a placard in a grocer's window, cautioning people against purchasing teas sold in lead packets, and describing the effect of the lead as most pernicious to health. From conversation had by me with a doctor, the conclusion seemed evident that where tea has been so packed for any great length of time it may be that it takes up some of the injurious qualities of the wrapping. Many years ago it chanced to me to be acquainted with the Rev. Joseph Sortain of Brighton, a very popular preacher there in those days, and brother to the late Dr. Sortain of Batticaloa. From some unexplained cause his health failed most seriously, and none of the doctors who attended him could trace a reason for it. At length his habit of profuse snuff-taking attracted attention, and it was found that he always purchased his favorite mixture in lead packets. As the symptom of his illness were akin to those produced by lead poisoning, Mr. Sortain was recommended to obtain snuff which had not been so packed, and a change for the better commenced directly he followed this advice, subsequently recovering altogether. This incident leads me to think the advice above referred to as to tea may not be without pertinence, though we have

never seen cited any cases of illness which could be attributed to the action of lead on tea. It has been so packed in the chests for very many years without attention being directed to any deleterious effect; but, of course, the smaller bulk of tea in a packet of say a quarter pound weight, it is conceivable, absorb a larger proportion of the lead poison, and it will not surprise me to find the subject taken up some day as a topic of discussion in the newspapers, the editors of some of which are always on the lookout for some stirring matter of the kind to pad their columns with.

Mr. J. L. Shand tells me that, seeing Sir Alfred Dent recently, he heard from him of most satisfactory reports being received from his Andes expedition. Soil and climate in the territory to be ceded seems admirably adapted to the cultivation both of coffee and tea; but even when this fact is allowed for it will not necessarily mean that money will be forthcoming to undertake planting on a large scale. Recent events in South America have made capitalists here less inclined than ever to invest money in any of the South American republics, and it is a question if the Peruvian bondholders themselves, who have lost so much money in their former investments, will care to personally put their hands in their pockets to throw good money after bad. They certainly are not likely to obtain much aid from outsiders not interested like themselves.

Experiments are now being conducted by the Admiralty, which, if they should have the success anticipated by the promoters, may go far towards securing for your coconut planters more favourable returns. Here experiments are being made with what is termed cellulose of coconut. We understand this to be some preparation of the fibre, and it is said that it has the property of absorbing eight times its weight of water. As far as we understand, the experiments now proceeding at Portsmouth are being made with slabs of this material which are affixed inside the iron plates, and the advantage claimed is that in the event of a shot hole, the cellulose absorbs the inrush of water, swells and closes the shot hole. The slabs themselves are also said to be extremely difficult to penetrate, and they would therefore aid towards keeping out any shot or fragment which might pierce the plates to which they afford a backing. If this should prove to be the case, it is probable that a large demand will arise for the material, both for vessels of war and for those having only a commercial character.—London Cor.

SCIENCE IN THE TEA GARDEN.

About a year ago we noticed in our columns that an investigation on scientific lines into the cultivation and manufacture of Tea had been taken in hand by a Committee, representing the India Tea Association and the Agri-Horticultural Society of India, and that an agricultural chemist had been especially retained from England, to conduct the inquiry. We have now received an early copy of the first Progress Report, made by Mr. Bamber, the agricultural chemist referred to, showing the work done during the last twelve months. The Report points out that the inquiry resolves itself into two divisions, viz., the growth and cultivation of Tea, and its manufacture. The work done during the past year is confined to the first division, and although sufficient time has not elapsed for definite and final opinions to be given on the many difficult questions involved, we can congratulate the Committee on the progress which has been made. Short though the report is, it is full of food for reflection, and will repay the close study of all connected with the industry. We do not think it is too much to say that

the Report foreshadows changes which will mark an era in the industry. The Report is divided into four parts,—Introduction, growth, and cultivation, general suggestions and general remarks.

To show the manner in which the subjects have been handled, we give the heads under which growth and cultivation are dealt with:—“(a) Chemical composition and physical properties of the soil; (b) chemical composition of the Tea-bush (wood and leaves); (c) chemical composition, and value of manures used; (d) chemical composition, amount, and distribution of rain-fall.” Each of the subjects are sub-divided into sub-heads, and are concisely but clearly dealt with. We will content ourselves with two extracts: The first is from General Suggestions and lays down the *object of manuring*:—“The object of manuring is to return to the soil certain constituents of plant-food in which it is deficient, and which were either almost entirely absent from the soil in the first instance, or have been removed by continued cropping, or lost by drainage. Most soils contain nearly all the elements of the plant in abundance, with the exception of one or two of the more important constituents and it is these which must be returned or added to the soil to enable the plant to grow.” The second extract is also from the general suggestions under the head “Economy of Using Suitable Manures”:—“As mentioned in a previous part of this paper, tea soils differ considerably in chemical composition, some being deficient in only one or two plant constituents, while others are poor in all; consequently, a general manure cannot be economically applied in every case for in the first instance, where only one or two of the plant constituents are deficient, the application of these alone would be as beneficial as the application of all, and at a much lower cost; whereas, in the second case, where the soil is poor in all, the application of one or two only would have little or no effect, until the others, which are also deficient, have been supplied.”

The laws laid down here are not in themselves new, it is only that their application to Tea has apparently been lost sight of. At any rate, the replacing of the constituents of the soil used up by Tea in a scientific manner has not, we believe, been attempted practically. Should the Committee not prosecute the researches further, they have already done enough to convince practical agriculturists that money would be well spent in obtaining a full analysis of the soil of any portion of a Tea garden which it is proposed to manure, and in getting the advice of an expert on the kind and quantity of manure required. We hope that the inquiry will be continued, and that light may be thrown on the chemical changes which take place in the tea leaf during the process of manufacture. In these days of close competition, planters can no longer afford to continue manufacturing in ignorance of the laws and causes of the changes which go on under their eyes. It is curious to think that where so much capital and enterprise have been expended, the present is the first serious attempt to gain a scientific insight into the process of manufacture.—*Englishman*.

AGRICULTURAL WORK BY HORSE AND MARE POWER.

A LECTURE BY MR. J. H. B. HALLEN.

POONA, Dec. 10th.

Mr. J. H. B. Hallen, General Superintendent of Horse-Breeding Operations in India, delivered a highly interesting lecture yesterday evening at the Albert Edward Institute, Poona, on the subject of “Water-lifting and Agricultural Work By Horse and Mare Power.” Khan Bahadur Kazi Shahabudin, C.I.E., presided on the occasion, and there was a large attendance. Mr. Hallen having been introduced to the audience by the chairman proceeded with his lecture. He said:—In India bullocks are used for agricultural work, such as ploughing, harrowing, and raising water for irrigation purposes. They are found satisfactory workers, but their pace is slow—

about one mile per hour in the plough and about two miles in carts on roads. The price of bullocks for agricultural work vary from R15 to R50 each. For submerged and morass land buffaloes are better adapted. The price of a buffalo for such works is from R15 to R35 each. Their pace at plough is about one mile or less per hour. The cost of the keep of a bullock or buffalo varies from R2½ to R5 per mensem. In England for many years past only horses have been employed in ordinary farm work, as they are found able to do work at a faster pace, both at plough and ordinary cart work, and thus economy of time and saving of money results. Moreover, the horse power employed is chiefly mare-power, as mares do all work quite as well as stallions and geldings. Mares are allowed to breed on the farm, so that the farmer has the benefit of selling the produce thus obtained, if not required in the farm, and the money realised by the sale of the young horse stock, bred and reared on the farm, contributes to paying the rent of the farm, and very often the greater portion of it. The period of gestation in a mare is about eleven months, she can be used at slow agricultural work up to within a fortnight before the time of foaling, and again twelve or fourteen days after foaling, so that a brood farm mare can work for eleven months in the year. And she is in better health for having work, slow work and thereby becomes the more sure foal-producer; and her foal always is, as a rule, a stronger and more valuable animal. As in Europe, it may be accepted that horses will be found likewise in India more satisfactory working animals on a farm. Horses do not cost more for keep than bullocks, for it may be safely assumed that a horse or mare will do well on a diet that will not cost more than what a well-fed bullock gets. Horse-power is used generally throughout India for draught as well as saddle work. We see horses doing excellent work in carriages, dak gharris, tongas, ekkas, &c., and it is acknowledged that they can work well in saddle and in draught even under the tropical sun of India. It therefore seems strange that horses have not been used for agricultural purposes. Granted that the pace of a bullock is perhaps better adapted for the physical power of a native ploughman, but the latter has been found quite equal to working a plough with horses if given better wages and thereby having better food. A few years ago when at the Remcut Farm at Hoour, near Bangalore, I found that horses were always used for ploughing and other agricultural work in the farm, and I had the opportunity of seeing that they did their work in a most satisfactory manner. Shortly afterwards I had the chance of employing horse-power on the Government Farm in charge of the Horse-Breeding Department at Babugarh, near Meerut. Up to the time of my receiving charge of that farm bullock-power only had been used for the farm work. I suggested to Government that the bullocks should be disposed of and horse-power employed, and in order to prevent unnecessary expenditure in purchasing horses I asked that fifty pony mares, of a large number belonging to the Transport Department and no longer required at the expiration of the last Afghan Campaign, might be handed over to me to carry out the farm work. Sanction was accorded, and fifty pony mares arrived at the Depot Farm. These were animals of a very ordinary class, from 13 to 13½ in height, probably worth in the market from R25 to 50 each, and most of them had never been employed for brood purposes. The pony mares were soon broken into plough and harrow. The harness employed on the pair when at plough was similar to ordinary tonga harness, made in the bazaar by ordinary *moochies* at a cost of from R3½ to R4½ for the pair. With this harness the ponies pulled from their back—the best style of draught. The harness was found to answer, and by offering prizes for the best ploughing with the pony mares I was gratified to find that in three months' time several ploughmen able to do in a day with a pair of ponies much more than could be done by a pair of bullocks, and after a year or two the men were able to do half as much more ploughing in a day than

is done by ordinary bullocks. These pony mares were also employed in Persian wheels for lifting water from wells to irrigate fields in which lucerne guinea grass, dubs, carrots, &c., were grown. Likewise I had some of the mares used for raising water by the chursa or leather mashak. As I found some of the heavy work of the farm, such as pulling timber and ploughing very stiff land, was rather too much for the small pony mares, I was allowed to have twelve larger mares, from 14-2 to 15 hands, cast from regiments and batteries, and with these and the pony mares all the work in the farm, and the carrying of grain and forage in carts about the farm, and bringing bran, &c., from a railway station 24 miles off was duly performed. These mares were not groomed; when not at work they were allowed to graze in the fields; and they also had a small quantity of grain diet according to the work they performed—about 3 lb. daily. Each ploughman had to attend and care for two pairs of ponies. The mares, as they came in season, were mated with donkey stallions and the mule produce so obtained were highly satisfactory. The mules born were found to be hardy and easily reared. The cost of rearing was calculated at Rs 12 per month, and at the age of three years the mules were worth from Rs 150 to Rs 250 each. Mule-breeding is therefore a paying industry. But my present wishes are to induce the public to look upon the horse as an animal as useful as a bullock on a farm, and if mares are employed, then the profit, arising from using them as horse or mule breeders, is apparent. If the agricultural community will use horses for farm work, the horse-breeding industry will become extended, and the requirements of the public and State, as regards horses, will be secured in the local markets. At present horse and mule breeding are limited in extent; hence why importers bring horses and mules from distant countries—Australia, Persia, Arabia and the Cape of Good Hope, to supply the wants of the State and public. The large amount of money required to pay for these foreign horses and mules is given for the benefit of other countries, not for India. But India, with its congenial climate, in districts away from the lowlands of the coast, especially in Northern India, is particularly well suited for horse and mule breeding; and surely it will be good policy for breeders, in suitable districts, to follow horse and mule breeding as a part of agricultural work, and thus in time provide all horses and mules required in India, and the money now sent to foreign countries will be distributed amongst breeders of Indian horse and mule stock. I have to earnestly recommend the native gentlemen I have the pleasure of addressing may explain to farmers and others what I have described in my address, and I would solicit their kind co-operation in inducing every employer of bullocks to use mares instead, and thus have the profit obtainable from the mares as breeders. I would ask you to accept all I have said as the result of practical experience, and as that practical experience has convinced me of the pecuniary advantage derivable from using horse and mare power, so do I deem it my duty to inform the public of India, with a view of allowing farmers and other bullock-keepers to become aware of the satisfactory results from employing mares instead of bullocks.

In conclusion, Mr. Hallen gave a few statistics which went to show that more water could be raised by the "chain pump" in a given time, and with a similar amount of power, than with the chursa or Persian wheel, and he assured all who cared to visit the farm at Bahugarh of a hearty welcome. A course of technical instruction would be given at that farm to all who cared to learn the management of a farm and all its details.

The Chairman said that with the co-operation of a few of his friends he would address Government on the subject of Mr. Hallen's scheme, for he felt sure that the only way to get the public to take the matter up was through the Government.

In acknowledging the vote of thanks which was passed to him, Mr. Hallen said he was anxious that

such steps should be taken in the matter of horse and mule breeding as would make India independent of foreign sources. The improved indigenous horse was far better than the Australian. In India we had the basis, in the Asiatic animal, of the best horse for ordinary public services, and the best war horse. The best definition of a war horse was a horse that would go the longest distance, and perform hard work on the shortest commons.—*Times of India.*

CEYLON TEA IN SYDNEY.—A Sydney paper contains the following advertisement:—

THE MELBOURNE CUP IS PAST.
Latest Tin for Ceylon Cuf:
Golden Tip.

The increasing production of Ceylon Teas, and excellence of Teas grown in the island, have induced us to offer selections from the leading estates, superseding everything hitherto offered at the price; no outrageous names, but Ceylon pure and simple. No. 7, Choice Ceylon Pekoo Soueheng, handsome leaf, thick, rich, mellow, fine flavour, 2s per lb. No. 5, Choice Ceylon small leaf Pekoo, with delicious flavour and superb quality, 2s 6d per lb. No. 6, Extra Choice Ceylon Golden Orange Pekoo, a mass of golden tip, absolutely matchless in liquor, 3s. In families where a quantity of tea is consumed a large monetary saving will be effected by ordering this tea. Address, E. H. Harris & Co., Ceylon Tea Stores, 18 Royal Arcade, Sydney.

"THE TALLOW TREE" (*Sapium sebiferum*) AS A FUEL PLANT.—From Pussellawa a correspondent writes:—

"I am sending you a few seeds of the tallow tree, which is a strikingly handsome plant and an exceeding quick grower. The leaf is in shape something like the Bee, and here and there a leaf turns crimson like the maple. The seed case is round and bright purple bearing each two seeds. I thought that as it grows so very fast, it might be thought worth cultivating for fuel trees, and I send you an extract of what Dr. Trimen says about it."

From the extract sent, it appears that the tree was introduced to Ceylon about 70 years ago and has long since been naturalized in some of the hill districts. Candles are largely made in China from the fatty matter round the seeds. The wood is hard and would make good fuel. Our correspondent speaks of a tree growing most luxuriantly at an elevation of about 3,000 feet, the tree being fully 20 feet high at not 3 years old, making the quickest growth of any tree planted in the locality except the *Albizia* known in Assam as the *Sau*.

According to a recent writer in *Gartenflora* the so-called Century-plant (*Agave Americana*) was introduced into Europe during first century after the discovery of the New World. The blooming of one specimen is recorded as occurring at Avignon in 1599, and of another at Montpellier in 1647, while even as far north as Wurtemberg a specimen was seen in the latter years of the sixteenth century, the flower-stalk of which measured over twenty-four feet in height and more than two feet in diameter. A story is told of one which, in some town of Languedoc, under the eye of Louis XIII. and Cardinal Richelieu, threw up a flower-stem twenty-eight "hand-lengths" in height during the space of thirty-six hours, so greatly to the astonishment of the king that he decreed the "bawling stem" should be painted by "some admirable painter." The first illustration of *Agave Americana* was published by Lobelius, who died in the same year as Shakespeare. No docs not often realize, perhaps, that in the far-off days of Good Queen Bess American plants were already known in England as well as on the Continent, some of them being almost familiar objects, while as yet there were very few Americans except such as wore red skins.—*Garden and Forest.*

CEYLON TEA IN PARIS.

No doubt our readers will, equally with ourselves, have shared in the surprise expressed by our London correspondent (page 29) that Mr. Lough should, after having sought and obtained the agency for Ceylon teas in Paris, have seemed not only to coincide in, but to fully endorse, the wish of some of the shareholders of the *Palais Indien* Tea Houses Company that their sales should be confined exclusively to Indian growths. This matter appears to have been promptly taken up by the Tea Committee of the Ceylon Association in London. At first sight, there could seem to be no doubt that Mr. Lough had been guilty of a breach of faith in the statement he had made, and the Committee was not slow in calling him to account for it. We know that very grave objection was taken to the selection of Mr. Lough for the Paris agency, and that a very unpleasant correspondence between our local Association and that of London resulted. Had the matter remained unexplained, we must have held that the objections raised were most fully justified. But Mr. Lough, in replying to the questioning addressed to him by the London Association Committee, has stated that his remarks at his Company's meeting were not in any way intended to apply to Ceylon tea. What it was desired, he informed the Committee, was to exclude from such sale the teas of China, Japan, Java, and other similar teas of Far Eastern growth. We must, of course, accept this explanation, but can only express our regret that Mr. Lough, when speaking as he did at the meeting of the *Palais Indien* Company, had not been more explicit. Had he been so, and in accordance with the intention he has now expressed, he would have saved himself from a most unpleasant and by no means groundless suspicion of having contemplated a most unfair procedure. From the prospectus of the *Palais Indien* Company forwarded to us, we learn that the object of the formation of the company was "to promote and develop the use and sale, knowledge and appreciation, of Indian, Ceylon, and other teas, in Paris and other places on the Continent of Europe, and in the United States of America, Canada, and other parts of the World." This is a far-reaching project enough; and it is only fair to point out that the professed object did not limit the sale of teas to Indian varieties only. In deciding to restrict their sales to Indian teas alone as expressed at the meeting referred to, it would seem to us that the Company so far departed from the conditions under which it was registered, that it would have been feasible to have called in question the legality of its further operations as a registered concern. But it is needless for us to pursue further such an argument. The Company—in consequence, it may be presumed, of the objections raised by the London Ceylon Committee,—has approached the latter body with proposals to obtain the co-operation with it of our local Tea Fund Committee. We should say that, should such fusion be determined upon, a company must be registered upon a new basis, and possibly with largely increased capital. We can imagine many among us entertaining a doubt whether, in the event of a joint enterprise of the kind being undertaken, Ceylon, as the lesser vessel, may not run a chance of being pushed to the wall. However, we think we may safely leave the arrangements which should render us safe against such injustice to the skill and care of the gentlemen who are negotiating with the *Palais Indien* Company on behalf of the Ceylon Association in London. The names of those gentlemen as given in our London

letter should form a sufficient guarantee that our interests will be well looked after and secured. Knowing as we do, how good a footing the Indian Company has already secured in Paris, it is evident to us that, if it can be done, it will be best to work in co-operation with it, if possible, rather than to start a new and separate venture on our own account. We by no means overlook the possible difficulties that may have to be faced in securing that Ceylon teas shall enjoy their full and due share of attention. If Mr. Lough, as the Superintendent of the Paris Tea House, carries out faithfully the engagements he has entered into in accepting the position of our recognised agent, there should exist no doubt that this would be secured; but as man is but fallible, it will certainly be necessary that our London Tea Committee should closely scrutinize all the operations, and insist, *ab initio*, that the teas of both India and Ceylon should be offered to customers in certain defined proportions. Of course such customers may have, and may express, their preference for one or other of the two varieties, and their taste in this respect will have to be consulted and deferred to. But apart from this, there should be no favoritism shown by Mr. Lough to either kind of tea. Let each stand or fall by its merits, and we have no fear that Ceylon will not take its proper place. It is on this account that, notwithstanding the difficulties we can foresee, we hope that the arrangements now under discussion may result in a consequent working advantageous to the growers both of India and Ceylon. But the leaders of the Tea Fund and of the Planters' Association will rightly claim a voice in any decision that may be arrived at.

◆

COFFEE GROWING IN BRAZIL: ITS BRIGHT PRESENT AND DOUBTFUL FUTURE.

Mr. Scott Blacklaw's latest instalment of the elaborate and deeply interesting notes on the progress of railways and agriculture in Brazil, with which for years back he has enriched our columns, will be well received by all intelligent readers, while it will be difficult for many of our planters who spent the best parts of their lives in the culture of coffee, to repress some feeling of envy as they read of the prosperous extensions of that culture in virgin soil, where three-quarters of a ton per acre are yielded, where railway facilities are present with a sufficiency of labour, and where leaf fungus (of the fatal kind) is unknown. There seem to be scarcely any bounds in Brazil to the area of suitable land in a suitable climate, while, hitherto, capital for railways and to enable the planters to procure and pay for labour has been readily available. But alas! Brazil, which under monarchical government enjoyed peace and order, must needs follow the example of other South American States, and submit to a dictatorship under the specious guise of a republic. The parallel is complete in anarchy and loss of credit, intrigue and civil strife. Mr. Blacklaw, of course, being a stranger in the land, says nothing of all this. But, his valuable communications are continued, we fear his next instalment of notes will bear a different aspect to the sunshine of the present,—the picture being marked by the shades of the arrest and decadence of enterprise, from the absence of capital and the labour which capital alone can command. There is no doubt a certain amount of capital in the country itself; but its possessors will be just as unwilling to incur risk, in the present unsettled state of government and politics, as the

English capitalists on whom enterprize in Brazil has been and is so largely dependent. Of course matters may soon settle down, and a strong government may re-establish peace and order. But we confess our fears preponderate over our hopes; and we suspect that the world must look beyond Brazil for much of its supplies of coffee.

THE DUTCH MARKET.

AMSTERDAM, NOV. 27TH.

The cinchona auctions to be held in Amsterdam on December 17th, 1891, will consist of 5,752 packages (5,365 balos and 387 cases), about 498 tons, divided as follows: from Government plantations, 290 balos 75 cases, about 28 tons; from private plantations, 5,075 balos 312 cases, about 470 tons. This quantity contains of *Druggist's bark*—Succirubra quills, 2 balos 281 cases; broken quills and chips, 95 balos 15 cases; root, 75 balos. *Manufacturing bark*—Officialis quills, 52 cases; broken quills and chips, 83 balos; root 31 balos. *Lodgeriana quills*, 11 balos 39 cases; broken quills and chips, 3,719 balos; root, 1,027 balos. Hybrid broken quills and chips, 255 balos; root, 87 balos. Total, 5,365 balos 387 cases. The dates of the Amsterdam cinchona sales in 1892 have been fixed as follows:—January 21st, February 25th, March 31st, May 5th, June 9th, July 14th, August 25th, September 29th, November 3rd, December 8th.—*Chemist and Druggist.*

TEA PLANTING IN THE WYNAAD.

We have been favoured with some particulars of tea planting in the Wynaad which promise well for the development of a future tea industry in that district, where a good deal of tea has been planted during the past two years. The plants thrive well, and the variety that has been selected for cultivation is highly spoken of. The following is a report and valuation by a Colombo broker on tea grown on the Richmond estate at Pandalur, in the Wynaad, planted in 1889, and forwarded 20 miles to the Neddintum tea factory for manufacture:—

ORANGE PEKOE.—Black bright golden tips, good style and appearance, wiry, well twisted leaf. London value, 1s 8d to 2s.

BROKEN PEKOE.—Black flakey fannings; style, tippy good appearance. London value 9d.

PEKOE.—Black, rather bold, rather even, wiry, well twisted leaf, tippy, good appearance. London value 9d.

PEKOE SOUCHON.—Blackish, greyish, rather open little flattish leaf, little wiry, some ends. London value 8d to 9d.

DUST.—Black brownish flakey tippy fannings. London value 7d to 8d.

FERMENTATION, bright, even, coppery.

LIQUOR.—Strong full pungent.

These teas are very well made, and bright infusions. Fermentation very nice.

(Signed) A. M. GEPP.

Colombo, November 30th.

A Ceylon planter gives the following opinion on these teas:—"I have examined and tasted your 'Richmond' samples. They are fine teas, good strength and flavour, though the latter is quite different to any flavoury teas I have tasted grown in Ceylon: they taste more like Darjeeling teas. If you can make such teas in Wynaad it is a good lookout. The appearance of the leaf is not first-class, the leaf being too grey. The Orange Pekoe is, however, handsome; the B. P. is very broken and flakey. Recently the market has wanted more leafy and less Broken Pekoe. The fermentation is first rate, and I shall be very interested to know what these teas fetch in London. I could not value them unless I know something of the size of the break, but they should average 1s 3d to 1s 4d per lb. if the proportions of Orange Pekoe and Broken Pekoe are right. In fact, I think this a low valuation."

Mr. W. M. Staudou, who manufactured these teas, has expressed himself about them in the following

terms:—"With adequate machinery, anything over 7d per lb. means profit, and 4d per lb. profit on a yield of only 450 lb. per acre means £7 10 per acre per annum. I do not believe any amount of over production will hurt the growers of this class of tea, for long before they could suffer an appreciative reduction in value, half the estates in India and Ceylon would be ruined. I firmly believe that there is a great future for tea in the Wynaad. Tea of good *jal* still affords an excellent investment." We may mention that the average value of Indian and Ceylon tea is about 9d.—*M. Mail.*

[The bunkum about half the estates in India and Ceylon being ruined, before such teas as Mr. Standen has manufactured being over-produced, simply proves the man's own silly egotism.—Ed. T. A.]

MR. A. SCOTT BLACKLAW ON AGRICULTURAL ENTERPRISE AND CONNECTED TOPICS IN BRAZIL.

COFFEE AND OTHER CULTIVATION IN RIBEIRÃO PRETO—ILEX PARAGUAIENSIS—RAILWAY EXTENSIONS—EUROPEAN IMMIGRATION—DESCRIPTION OF THE COUNTRY AROUND.

Rio, Oct. 15.

Ribeirão Preto.—I mentioned before that coffee planting was begun here some twelve years ago.

Our late lamented friend G. A. Critwell and the writer passed through parts of this same district in 1876. At that time there was very little talk of land being bought here for planting coffee, and there was not such a town as the now important "*Ribeirão Preto*" which numbers at present some 8,000 inhabitants in existence.

We noted at the time of our visit (1876) some very nice coffee patches near some of the native huts, and we observed that the soil was of superior quality. It was very forcibly impressed on our mind, that what was called virgin forest was of a low short kind, with very few of the great giants, unless of the fig-tree species, which grows very fast.

The district at that time had the name of being feverish, and the climate was thought too cold for coffee. Some plantations had been opened on a small scale in the sixties, but the great frost of 1871 had killed all the trees, and thus damped the prospect of future pioneers. At the time we passed this any quantity of land could have been brought for very little money.

The lands were in possession of people who had descended from the great highlands of Brazil, in the Province of Minas Geraes some years before. Originally the lands were granted to leading half-caste—mixed descendants of Portuguese and Indian—families by the Portuguese Government before the independence. The blocks were given and the area counted in so many square leagues, and called "*Seismarias*." The seismoira, as the grantee was called, was by his title obliged to have a house on, and cultivate a certain quantity of the land and houses were thus few and far between. It was from these first settlers, that the invading "*mineiro*" from the north obtained these large blocks.

These pieces of land were not *always* bought, and if a sale were made at all, it was of only a small piece, and the occupier of the small piece encroached on his neighbour's land.

"The good old rule sufficed them, the simple plan

That they should take who had the power,

And they should keep who can."

Some good honest men did however pay for their land, and one family in particular to whom the writer was afterwards introduced, consisting of a widow and some three or four stalwart sons, were living—at the time we allude to (1876)—on 860,000

acres of land for which the late husband of the former, and father of the latter, paid three thousand pounds sterling (or 30,000,000 in Brazilian currency).

The mineiro's mode of farming was a peculiar one, and not at all likely to improve the land or make it what we could call first class for coffee growing afterwards.

His system was to fell the finest virgin forest, clear the land, by burning the withered branches, and plant the clearing with Indian corn, with a fair sprinkling of pumpkin seeds. Virgin forest has no weeds, and consequently no work was required until the corn was ripe; only what was needed for home consumption was picked, then a drove of pigs were turned into the corn fields to fatten. Tusco porkers grew to a good size and put on a large quantity of fat. The mode of preparing the pork for the market was thus. After the pig was killed a heap of corn straw was piled on the top of the carcass, this was set fire to, and the burnt hair, and flakes of outside skin came easily off, the pig was then cut in two longitudinally, the bones carefully taken out, deep cuts, three inches apart, were made across in the inside, these cuts were filled with salt. Each half carcass was made into a roll, and put in a rough bambu basket, made the size. It was then ready for the market. If the farmer had a troop of mules himself, he would take these baskets with their contents loaded on pack saddles to sell, sometimes going as far as the capital to find a market for this class of goods which got the name of *toucinho*. There was also no want of local agents, owners of troops of mules, who would buy *toucinho* at so much an arroba of 15 kilos, and send it to the best paying market.

Many of the more industrious of the farmers grow tobacco: the leaves were half dried, twisted like a rope of many strands with a "throw crook," and the rope rolled on a stick. The ends of this stick projected, the rolls were put on end, leaning against a wall or a fence rail. The black juice would ooze out and drain towards the lower end, and when this was noticed the roll would be turned end for end. This fermenting process was continued for some days until the sweating ceased. Some farmers had a famous reputation for curing tobacco, and tobacco from some special districts was considered extra fine, and sold at a high price. The same system of curing in Minas and S. Paul's tobacco still continues. In the consuming of the weed the country people put their tobacco on a piece of the roll which they carry in their pocket, and make cigarettes with fine maize straw, every time they smoke. But in towns tobaccoists have machines for cutting it up like "bird's eye" for sale or for making cigarettes. There is a large consumption of cigarettes all over South America, made from both paper and Indian corn straw. The Brazilian prefers the latter. The habit of smoking is common both amongst males and females. It is noticeable amongst the lower classes that the female always smokes a *pipe*, with a clay bowl, and a stick for a shank. The stick is got from the branch of a particular bush which in place of pith has a small perforation down the centre. The males both of the upper and lower classes nearly always smoke cigarettes. I have noticed that in some parts of the littoral of the Province of Rio de Janeiro the smoker carries a bundle of leaves in his pockets, makes his own cigar and smokes it in one's presence, generally offering at the same time the cigar to the person with whom he may be conversing.

Small patches of cane were also grown, and the product after supplying the needs of the family was made into briquettes, rolled in banana or corn leaves, something like your jaggery—but

called here *rapadura*. The cane crushing was done with wooden vertical rollers with bullocks, and the concentrating of the juice was effected in a large copper boiler. Query has the word "sugar" come from "jaggery" or "jaggery" from "sugar"? You orientale ought to know if the latter word or the Tamil "sakara"—was in use before Vasco da Gama made his famous voyage!

The very poor people in those parts use the pure juice of the cane instead of water and sugar in the preparing of the cheering but not intoxicating liquors made from coffee, mate and the *congonha*. The former two were all well acquainted with, but I myself did not know of the latter at least by name. It was only on my recent visit to Minas that my attention was called to it. *Congonha* in my opinion is a kind of mate, *Ilex Paraguaiensis*.—There are two kinds of it in Minas, one *congonha de matto* (forest), the other *congonha de campo* (patane). The leaves are used green as they are taken from the bush. They are dried hastily in an oven or at the open fire, then put into the tea-pot along with a few small pieces of burning charcoal and well shaken together, water is then added, and the charcoal skimmed off the top of the liquid which after a few minutes is ready for drinking. Its refreshing effects are similar to those of tea or coffee.

I mentioned before that in these parts the people produced the raw material which they made into cloth for clothing which was not confined entirely to cotton; woolen blankets and sometimes complete suits, could be seen of good "home spun."

Thus in their simple state lived the people in the West of the Province of São Paulo and South of Minas Geraes. What they required from outside their own homes was little.

But a mighty civilizing agency was at work in the east. The calm peacefulness of these regions was doomed to be intruded on, in a few years by that giant of colonial development—a railway.

At the time of G. A. C.'s visit along with the writer, 1876, the railway had been opened as far as Riobras on the 5' 3" gauge, and to Mogyimirim on the metre, those two places being the farthest westward that coffee planting extended. As soon as it began to be noticed that the Mogyana railway was to be a paying one, no time was lost in raising capital for its extension. The capital was supplied by wealthy capitalists, and planters in the country.

* In answer to this question we quote as follows from Yule's "Hie'son Jobson":—

SUGAR, s. This familiar word is of Sanskrit origin. *Sarkara* originally signifies 'grit or gravel,' thence crystallized sugar, and through a Prakrit form *sakkara* gave the Persian *shakkar*, the Greek *σακχαρ* and *σακχαρον*, and the late Latin *saccharum*. The Arabic is *sukkar*, or with the article *as-sukkar*, and it is probable that our modern forms, It. *zucchero* and *succhero*, Fr. *sucre*, Germ. *Zucker*, Eng. *sugar*, came, as well as the Span. *azucar* and Port. *assucar*, from the Arabic direct, and not through Latin or Greek.* In fact the ancient knowledge of the product was slight and vague, and it was by the Arabs that the cultivation of the sugarcane was introduced into Egypt, Sicily, and Andalusia. It is possible indeed, and not improbable, that palm-sugar (see JAGGERY) is a much older product than that of the cane. The original habitat of the latter is not known; there is only a slight and doubtful statement of Loureiro, who, in speaking of Cochin-China, uses the words "habitat et colitur"—which may imply its existence in a wild state, as well as under cultivation, in that country. Dr. Candolle assigns its earliest production to the country extending from Cochin-China to Bengal.

* The Russian is *sakhar*; Polish, *zukier*; Hung., *zukur*.

The extensions went from Mogyimir to Casa Branca, from Casa Branca to St. Simon, and lastly to Ribeirão Preto. The very idea that these extensions might be carried out sent people from the districts of Rio de Janeiro and São Paulo, where coffee was beginning to grow seedy, in search of new fields and these paid what the old land owners thought a good price, and very soon large tracts of forestland were levelled by the axes of the free natives of these parts. The apprehended scarcity of labour was met by the introduction of European colonists, on a system which I have formerly described in these notes. Colonists make money on young coffee plantations, for the reason that in addition to so much paid for each thousand trees (about 3 acres) for weeding, they were allowed to plant corn and beans between the rows of coffee until the latter covered the ground and these cereals after leaving abundance to supply the house and the piggery, they generally sell to good advantage.

The pioneers in the settling of European colonists on coffee lands (among whom the writer was amongst the first), had a great deal to suffer, in loss of patience and proprietors lost heavily by their running up large debit accounts and then leaving without paying advances, but now after an absence of some years from the Province of S. Paulo, and witnessing the system, now much improved by the Government paying the passage money, it must be pronounced a success, as regards the cultivation of coffee. But with the large number of European families, who have arrived here during the last eight years, there is still a scarcity of labourers, owing to the rapid extension of coffee planting.

The districts traversed by the Mogyana railway supply nearly three-fourths of the exports to foreign ports from Santos. The total crop shipped from that port may be put down at 2,000,000 bags, of 60 kilos each for 1889-90. Of this quantity the district of Ribeirão Preto alone supplies about 250,000 bags. We see then that the reason of increase of production is entirely due to the extension of the railway system.

These districts ever since they were opened to coffee cultivation were entirely independent of slave labour, they depended in their supply to the free labourers,—fairly abundant, but very unmanageable—and to European colonists, if not imported direct, taken from other estates—not altogether "crimped" as the debt on the estate they left was always paid.

Let us see what the official report gives of the current of European immigration for the last eight years applied to São Paulo alone:—

1882	...	2,743	or a total of 176,442
1883	...	4,912	immigrants.
1884	...	4,879	
1885	...	6,500	
1886	...	9,536	
1887	...	27,689	
1888	...	74,497	
1889	...	17,283	
1890	...	27,883	

I need not go over the figures of the production of coffee, which has gradually risen from 500 000 bags in 1874 to 2,000,000 bags, of 60 kilos in 1890; this in round numbers and as the production will increase according to the quantity of labour available, the ruling powers are aiding the farmers liberally in their efforts to introduce European labourers, we may conclude that the exports of coffee from Santos will continue to increase as long as these efforts continue.

The present digression is perhaps instructive, as showing how rapidly the state of agriculture advances in new countries as soon as means of

communication are secured. We are now re-visiting the country after a few years absence: its state formerly is described above, and let us see it now.

I was as you may expect all anxiety to be on horseback, and after resting for a day in town and making a programme of how a run through these coffee covered hills could be effected, in the few days at my disposal, the equipment for the trip was arranged. Fortunately my friend although he lived at the hotel had a house for supplying machinery and iron-work of all kinds and knew the most of the fazendeiros in the district, had little hesitation in combining business with pleasure, and was willing to accompany me for a few days.

Close to the town of Ribeirão Preto there are not many coffee fazendas, for the reason that it is situated in the valley formed by the Ribeirão (small river) and the nearest highlands on which coffee can be planted, so as to be free from the visitation of frost are distant from six to eight miles. The horse hirer who was more punctual than we generally find such individuals in the towns in the interior, had animals waiting for us at day-light which at the season of the year, end of March was about 5-30 a.m.

The road on leaving the town goes south-west for three miles and then west. The valley reminds one a good deal of the pasture lands in Europe. It is laid out in beautiful fields planted with the grazing grass of the country, of which there are several kinds, and surrounded by fences, some made of thorns (of a leguminaceous species, which throws out long shoots, these shoots are cut half through once a year and folded down, and as they continue to grow and send out secondaries form a formidable obstacle which domestic animals of a wild nature cannot break through) others of wirefencing (now greatly used here) while on farms belonging to those of little capital are found a five bar fence of bamboos. Little attention is paid to shade-trees and still less to shrubbery of an ornamental kind, although many beautiful flowering plants showing varied colours and delicious scents of all sizes up to the largest tree are to be found in the neighbouring woods.

A great many vendas are passed where the principal article sold is rum, and about five miles from town we came to a large store, where every thing that there is a demand for in the country is sold, and where they buy everything that the labourers of the country may grow for sale, and also what the latter may possess themselves of by doubtfully honest means. The place had all its standing space in every part occupied by Italians, men and women, and owing to so many speaking, shouting, and drinking healths in Italian wine (said to be manufactured at a large liquor factory in São Paulo) the beautiful musical language of Southern Europe was mixed with the jargon of the "Cabocolo." This is the name given to the mixture between the Brazilian Indian and the white; they are copper-coloured, but have straight black hair with a Mergolian looking face. Free day labourers here, in the west are mostly of these Cabocolo and the boisterous laughter of the African resembled the confusedly babbling noise which we read of as having been heard long years ago in the plain of Shinar.

My companion who had passed this way often was soon recognized by the owner. We were shown real English beer, Guinness's stout, and other genuine liquors of this class, but seeing it was not yet the sixth hour of the day nor even the third, we could not be tempted, but we were greatly refreshed by the usual cup of black coffee, which kept off the craving for breakfast which we were now beginning to feel.

Some miles farther on, we came to the fazenda of

the lato John Gomes o. E., and where his widow lives. The land lies on a gentle slope, seems to have been large chena land, judging by the absence of characteristic tree stumps which are left protruding above the highest coffee trees if latter be planted in virgin soil. Coffee seems planted the regulation distance 16 by 16 palmas ($11\frac{1}{2}$ by $11\frac{1}{2}$ feet), the older coffee covers the ground well and the younger is very equal in height. There is a saw mill, a vertical one, which we notices from the road sawing up huge logs which have been taken from a clump of virgin forest in low land which would be subject to frost. We rode for about a mile through the plantation ascending the hill all the time. From the top of the hill a nice view is got of the valley through which we have ridden. We see hills covered with green coffee trees, on the two sides of the valley. After passing through a piece of large chena on the top of the hill, we commence to descend on the other side, and soon we enter another coffee plantation. This one had been badly treated and but four years ago was purchased by its present owner for a small sum. The new owner cut down the first planted trees about a foot from the ground, and the result now is a beautiful field of dark green coffee bushes, with not much crop for coming season, but a flush of young wood for the coming blooming season. Sept. and October.

The owner now asks £10,000—for what he paid £3,000.

We now descend gradually down the right side of another valley; the stream in the middle of it runs in a different direction, from that we have come and we find we are on a range of hills; which seems to be formed from the parent hill we have just crossed.

Through long geological ages they have been forming, for we find these ridges all run parallel with undulating hollows through which runs a stream. Almost every available piece of forest on the upper slopes is planted with coffee of ages from one to seven years and in many cases just newly cleared and planted. In the distance are seen further ranges of hills covered with coffee, or newly burnt clearings.

We rode along the side of this valley for a few miles and then we arrived at our headquarters for the day, the fazenda of "Larradas." This Fazenda forms one of a group of some four or five estates belonging to the Jorquero family the same to whom I have referred in these present notes as having been the holders of 360,000 acres in 1876. This group now forms the remnant of that large block. Beginning with the breaking up of the block in 1873, in three years it was all sold except what they now retain, and that is about 5,000 acres.

The proceeds of the sales—although receiving what would be called a small price per acre for coffee land—made them all (the members of the family) very rich. They were thus in a position to build houses for, and locate on their lands many European colonist families; consequently their coffee fields—from the time they were planted, unlike many others here have been kept in first rate order. The acreage under coffee of all ages is about 3,000 or 1,000,000 trees.

The rest of their land is pasture or forest under what we may call the *Frost line*.

It is in the hollows in the midst of artificially made pastures where are located the colonists' houses, nice looking white-washed tile covered buildings. After partaking of a hearty breakfast which was no equal to any of the finest country hotel breakfasts, at the house of Senhor Joaquim Peimino de Andrade Junquero and enjoying a cigarette—made of some tobacco of his own growing (in which he prided himself as being equal to the best

grown in these famous tobacco growing western lands)—and a cup of strong but full-flavoured black coffee—fresh horses were supplied to us, and we began in Visiting Agent style an inspection of these groups of estates.

I can scarcely express the pleasure this gave. The old Ceylon life came back to me, and but for the extra height of the trees, and the less accidental nature of the formation of the land, one could imagine one's self riding through the Hunasgiriya, Matale East, and Kelebokka districts in the days of old.

Our road at first was across the pasture, passing on the way a large village of Italian colonists. The contented look of the old people, and the healthy look of the children who were playing about as if they were in Southern Europe, the well filled corn houses situated in the back yard, the piggery and the fowl house, the enclosure for the calf to keep it away from the cow, the open stable for a horse, and last but not least in the back yard the large dome, well clayed over which serves for an oven, all inclined to make us believe that whatever may be said to the contrary, these people have not only bettered their position, but are supplying a necessary want to the cultivation of coffee in this country.

A barbed wire fence divides the pasture from the coffee fields. The large regulation wooden gate, which takes the strength of a man on horseback to open, and being hung at an angle closes automatically with tremendous force, is generally held open by the first of a group of people who may pass through. Here we have a delightful sight, coffee six and seven years old so loaded with green fruit that the branches were bending down to the ground. The trees are about twelve feet high planted 16 by 16 palmas ($11\frac{1}{2}$ x $11\frac{1}{2}$ feet) not a weed was to be seen and not an open space, to get along; the labourers had to bend their bodies or almost crawl. I should say there was about 15 cwt. to the acre, the green berries were well filled and at this season (April) many were growing yellow. (The picking season extends over June, July, August, September and October.)

The roads are all made on straight lines, wide enough for cart traffic and they all run at right angles. In picking the coffee cherry is heaped at the side of the road and a cart comes and takes it away to the barbaeco, where it is dried in the cherry. Owing to the style of picking—taking half ripe, full ripe and dried beans, which may be on the trees or on the ground, very little is done in the way of pulping. Very little rain falls during the picking season, from June to October, therefore the cherry lies outside on the barbaeco until it is dry enough for storing without heating. Admirable machines are now in use for hulling, and this is done at any time during the year. Coffee keeps its colour better in the dry cherry than when it is cleaned. So if the farmer wishes to wait for a high price later in the season, he keeps it in store un-hulled. The rule however is that he tries to get it off to market as soon as he can.

Young coffee is treated similarly to what it is in your country but it is not topped. A great many plants with seed, that is to say four or five coffee beans are put into each hole and after two years all but two are pulled out. The leaving of two plants is a new custom for formerly all planting was done by coffee plants from a nursery large enough to be made into stumps $\frac{3}{4}$ to $\frac{1}{2}$ an inch in diameter and only one to each hole. The pulled out plants do well for supplying vacancies or for planting up new clearings, but they must be pulled when the soil is soft and moist after or during heavy rain; no damage is done to the roots of those

which remain. There is little wind, so no staking is required. Indian corn is grown between the rows of coffee until the latter nearly covers the ground, one crop of black beans a year is also taken off. This latter forms the principal ingredient, indeed the base of the food and is as necessary in Brazil as oatmeal is in Scotland.

The price here paid to colonist families for treating *i. e.*, cultivating coffee, each family receiving from 1,000 to 5,000 or more trees divided off for the year, or succession of years is, for—

Five weedings a year 50\$000 (£5) per 1,000 trees (3 acres) per annum.

For picking the cherry and carrying it to the road 300 reis (7½d) per box of 50 litres (say 1½ bushel).

The planter prepares it for, and sends it to the market. At this rate, although I have not time to go into the figures coffee pays well. *But* all depends on the supply of colonist labour. In Brazil as in every other place if cultivation or treatment (here reduced to only keeping it clean) be neglected coffee will not pay.

From this estate we passed on to another in charge of a brother-in-law, then to those of other two brothers, all these occupying the block of 5,000 acres amongst them. Coffee was seen at all ages from 8 years downwards. On each division was a curing establishment, and a saw mill, a corn grinding mill, for colonists make bread of corn meal—mandioca preparing machines, chaff-cutters, &c. On each is also a store for supplying all the necessities of the colonists in the way of food, clothing, tools, luxuries &c. so that they have not to go to the town for anything but for amusement, or services of the church.

The price paid for opening new clearings and bringing coffee into bearing, that is for four years, is 400 reis (10d) per tree for the four years (1,000 trees to 3 acres). The farmer engages natives of the country to fell the forest; but charges this to the colonist. The farmer also gives a skilled man for lining free of cost. In addition to the 400 reis a tree for four years, the colonist has all the Indian corn, and beans he may plant between the rows of coffee and gather during that time, which is of considerable value. So much is the income to the colonist in the bringing of young coffee into its bearing state, prized by them, that they flock from long distances as soon as they hear of new clearings being opened in particular parts, and leave the older coffee where their income is for the price for weeding and picking only. We must recollect the colonist in any case has a piece of land in the valley for growing food supplies, and is allowed the use of the general pasture for cows or mules.

During my stay here I visited many coffee estates all more or less in condition similar to the above. This visit impressed me very favourably, as to the future of coffee planting in the São Paulo. It remains to be seen if the labour supply will be equal to the eager desire to extend the cultivation by men of capital.

A. SCOTT BLACKLAW.

REGULATION OF SUPPLIES.

To the Editor of the *Home and Colonial Mail*.
SIR,—When illustrating the difficulty of securing a combination to regulate sales, I said that those who imported tea brought in Calcutta (approximately one-third of the whole) could not be included.

As this is not a self-evident proposition, I will try to show that it is a true one, and to explain its bearing upon the question under discussion.

1. The objects and interests of Calcutta buyers

are not identical with those of the producer. It is of primary importance to them that prices in London should quickly take a range based upon the relation of supply to demand; consequently, if prospects are not distinctly favourable to a *permanent upward movement*, they regard a temporary inflation of price as an element of danger, to be avoided, not to be encouraged.

2. Freedom to press sales in case of need is essential to them, if their operations are systematic, and continuously carried on.

3. Most of their transactions are financed on terms which limit their power to hold.

We are, therefore, in presence of a large section, compelled, by the nature of the case, to hold aloof from concerted action. To these must be added those actual producers whose financial arrangements make it inconvenient to them to hold, and it is found that fully one-half of the importing community cannot be brought into combination for this particular purpose. Now let us assume that the other half organize and agree in a policy of keeping back supplies; what happens? They simply make the market for the others, who get the full benefit of demand, and supply the buyers with what they want, leaving the holders over-stocked, running the risk of the unknown future, with the added disadvantage of extra charges, loss of freshness, &c.

This, sir, is no fancy sketch; I speak of what I know. It has happened before and will happen again when the conditions are not favourable to prices holding up on their merits. Mark the qualification, for I refer to *past* action, and am justifying the course which the great importing houses have taken, since its wisdom has been called in question. Under different circumstances a different policy might be pursued or attempted; it may, indeed, be that the time is very near when sellers will be in a much stronger position. If so, individual judgment and action will effect what is wanted. It is a grave matter that those who hold a fiduciary position either as managing agents, directors, or brokers, should be publicly charged with mismanagement amounting to dereliction of duty.

But they need no justification. Facts must convince reasoning fail, and Mr. Shillington, with candour if doing him infinite credit, has quoted figures which put him and "Observer" out of court. What does he tell us? That although ten million pounds more have come from India not a pound more has been consumed in England. Larger consumption at any cost is, therefore, an absolute necessity to us; and we have now the satisfaction of seeing more being used than ever before. But would this be the case if supplies had been kept back, and the field left free to the sellers of China and Ceylon tea? I am really ashamed to re-state the elementary principles of economics; but it is the A. B. C. of trade that consumption expands when distributors hold stocks and shrinks when they do not, and the reason is obvious—they have become co-partners with the producer, directly interested in pushing the sale of his product.

What is to be the upshot of this correspondence? A fuller appreciation, it may be, of the complexity of the problems which face us; a check, I hope, to the passing of hasty and immature criticism upon others, but most certainly not any discouragement of co-operation among producers. That is most earnestly to be desired, but let its aim be something practical, fraught with substantial benefit to every individual man of them. The confinement of production within certain limits would be such an aim—but even that would be useless if the Ceylon planters refused to join hands with us; for if a reduction in India is to be the signal for an increase in Ceylon, we had far better fight for our own hand, and brace ourselves for the struggle which the prophets of evil say is inevitable. Remember, that when it was seen two months ago that the Indian crop was short and the price rising, word was passed round Ceylon to make all the tea they could*—the object being, of course, to hasten

* There was no such combination; the large quantities of tea were made because under the influence of the weather the bushes flushed luxuriantly.—Ed. T. A.

the displacement of Indian. It was done, and who can blame the Ceylon planters? But they smashed our market, and their own too, and created the position in which we now jointly find ourselves—which, after all, is not so bad as it might be.—
Yours, &c. VIS UNITA FORTIOR.

THE LABOUR PROBLEM IN ASSAM.

More than one leading planter has written to us to point out the evils of the present system of recruiting labour for the Assam tea gardens. We do not doubt that the matter has the attention not only of Government but of the agency houses, and that all that is possible is being done to remedy the evil. It may strengthen their hands if we try to consider briefly where the trouble lies. Statistics seem to show that Assam absorbs every year from 30,000 to 50,000 immigrants. We have every reason to believe that the planters would gladly take an even larger supply if the district's of recruitment could furnish it. During the last five years the average number of adults sent to Assam was 29,775, and of children 9,302. In 1889, a year of exceptionally large exportation, no less than 37,548 adults and 18,110 children were sent to Assam. It seems to be admitted that the supply of useful coolies, suited to the conditions of tea garden life is failing. Planters go further afield, to Ganjam, Jubbulpore and other remote places, and presumably have to pay more. Even these remote sources of supply must fail in time, for the Indian ryot does not migrate so readily as the Irish peasant, and the most vigorous recruiting, the most lavish expenditure is not likely to make any very sensible impression upon the crowded population of the recruiting districts.

At the end of 1889 the total labour force of Assam was 390,468. During 1890, 36,000 coolies, nearly 10 per cent, were imported; 17,000 in round numbers entered into contracts in Assam, 7,000 were received from other gardens, 500 deserters were recaptured, 14,000 remained on the gardens after the expiry of their contracts, some 23,000 were "otherwise obtained," and there were 10,000 births. Altogether the additions to the present or prospective labour force came to about 107,500 souls. This would have been an ample if it had been a real increase. It is instructive to balance against this the deductions: 4,500 coolies were transferred to other gardens (a number curiously less than the number received from other gardens), 50,600 left with permission, 14,000 died, 13,000 deserted, 7,500 labourers already working on gardens were put under contract, and about 400 coolies had their contracts cancelled for various reasons. Altogether there are about 90,000 souls to be written off. The net increase, therefore, was only about 17,500 and this in spite of 10,000 births and 36,000 new immigrants. Assuming that all the coolies who entered into contracts locally (17,000) and all the coolies "otherwise obtained" (23,000) were all old hands who re-engaged themselves, there was still a substantive and actual increase of 46,000 souls to the garden population. That the net increase was only 17,600 shows that the losses are heavy. Now it must be remembered that the cost of importing 36,000 new coolies was probably not less, at a very moderate computation, than two millions of rupees. This is the actual cost to the employer of landing 36,000 new, raw and, for a long time, perfectly useless hands in Assam. Many of these are bad bargains and represent a dead loss. As competition increases, the number of bad bargains increases, and there is an increasing tendency on the part of contractors to send up men from parts of India, the climatic and other conditions of which do not fit them for garden labour. The actual cost of really good working hands is therefore greater than our estimate. On the other hand, the labour laws enable employers to pay coolies a less rate of wage than would be possible under a system of free competition in labour, and accordingly a portion of

the initial expenditure is recouped in this way. But it is obviously inadvisable that employers of labour should be tempted in times of pressure, and on gardens which do not pay, to reduce wages to a minimum. One of the most important tasks which fall to the lot of an inspector of labourers is to satisfy himself that wages are adequate for healthy existence. But he is compelled to rely on averages; and some coolies, especially in the working season earn such good wages that many coolies may earn very poor wages without greatly affecting the average. Obviously wages are a very important item in dealing with the labour question and especially when it is remembered that the problem of increasing the area of exterior supply seems impossible of solution.

The way of deliverance seems to lie in conserving the existing labour force. What can be done in this direction? A high death-rate as compared with that of the ordinary rustic population is perhaps inevitable, especially on newly cleared gardens. Looking to the conditions of tea garden life, to the fact that the women work out of doors as well as the men, that many of the coolies are unaccustomed to new importations, it is perhaps surprising that the birth-rate does not fall extremely far behind the death-rate. But it is clear that of the 50,000 coolies who refused to renew their agreements and the 13,000 deserters, a very large proportion were lost to Assam, or at all events to the tea gardens. Some may have settled in the province as ordinary peasants, but the majority would seem to have disappeared. This is a very serious evil, when the cost of procuring new labour and the admitted evils of the present system of recruiting are remembered. Something may possibly be done in the way of reducing the death-rate, and the Government of India have very properly ordered stern measures to be taken with gardens which persistently show a high mortality. But from the employer's point of view the most disheartening thing is the loss of able-bodied labour by other means than death. That 13,000 coolies should have deserted in a single year is a serious matter when coolies are so expensive. We are not sufficiently acquainted with the details of tea-garden management to know whether many of these deserters engaged themselves on other gardens. The net deficit would seem to show that this is not the case.

The conclusion to which we are driven is that a great part of the labour force of Assam is kept in the province by the artificial means of the labour law. This law can be defended on the ground that labourers who have cost so much to import may righteously be deprived of their liberty for a while, and may be bound to labour for a term of years at a fixed rate of wages. But it seems clear that labour under these conditions is not really popular. The planting industry of Assam has been in full force and vigour for many years. Its conditions must be well-known by this time in the parts of India from which coolies are chiefly recruited. Yet the net increase last year, deducting the 10,000 births of children who, at present at all events, are not available for work, was under 8,000, though at least 36,000 souls were actually, and at enormous expense, imported.

We hope the suggestion we have to make may not be regarded as a truism. There are many obvious truths which are not always applied to practical life. Surely the remedy for the exorbitant expense of importation lies in the more careful conservation of the coolies who have found their way to Assam. At present coolies are kept on the gardens chiefly, as we have said, by the artificial means of the labour law, and by mere inertia. Some districts—and, judging by the last Immigration Report of the Assam Government, Sylhet seems to be one of them—have a sufficient supply of labour. Probably in such districts local conditions favour the labourer, and especially tend to make his wages sufficient for his comfort, health and happiness. These, it is noticeable, are the very districts in which importation is cheap: they

possess a comparatively large indigenous population, which supplies rice and other food stuff to the coolies. Apparently the average rate of wages in less popular districts ought to be much higher than in districts where food is cheaper and easier to be had. This may seem a hard saying to the planters, who may object that it is in these very districts that the expense and difficulty of importation become a crushing charge. "Whence," he may not unreasonably ask, "am I to recoup myself for the expense of importing fresh supplies?" Perhaps the best reply is to turn to the Immigration Report for concrete instances. We look up the wage lists at page 17, and confine ourselves, for simplicity, to men's wages alone. In the Surma Valley the average wages of men under the Act, taking five sub-divisions from west to east (the gardens furthest east being more remote and probably less popular) is as follows:—R4-3-1, R6-10-7, R3-14-10, R3-12-1, and finally in Cachar R4-8-6. But these figures are not so interesting as those of the Assam Valley proper, where the local conditions vary far more widely in different districts, and where, in Upper Assam, the coolie population bears a far larger proportion to the indigenous people. Lakhimpur, at the head of the Valley, has an immigrant population of over 70,000 out of a total of about 300,000. The average wage in this valley, going again from west to east, is—Kanrup, R3-15-2; Darrong, R5-8-8; Nowgong, R4-13-5; Sibsagar, R4-14-4; and Lakhimpur R5-4-4. It is plain on the face of it that wages do not increase by leaps and bounds as we travel into districts where the coolie is expensive to get and hard to keep.

But the figures hardly show how equal the wages are throughout the Valley. In the districts of Upper Assam the average is plainly kept up by the high wages paid to exceptionally useful coolies. While in Lower and Central Assam the highest wages paid to any Act coolie did not exceed R8 in Sibsagar so much as R15-4 and in Lakhimpur so much as R13-1-8 was earned by exceptionally good men. It may be taken roughly that the average rate of wages is about R5 some coolies earning two or three times as much, the majority earning less. Now in 1890, the district of Lakhimpur imported 7,668 adult coolies (a much smaller number than that of the previous year). This probably represented an expenditure of not less than R3,33,400, much of it spent on useless and unsatisfactory coolies. Now the annual strength of Act and non-Act adults and children in that district in 1890, was 72,128 souls. Assuming that each and all of these earned an average of R5 a month, the total expenditure only comes to R3,60,640. In other words the wages of all the existing labour force for a month are less, and probably much less, than the cost of importing the year's supply of new coolies. And we must bear in mind that old and seasoned coolies are infinitely better worth paying than raw and unhealthy new-comers. This is proved by the extremely high wages paid in individual cases. It can hardly be denied that the effect of the labour law is to keep down wages. Not only are coolies not under the Act better paid as a rule, but the Act by reducing competition has a tendency to keep down the wages of even free men. Is the advantage so obtained compensated for by the tremendous drain on the labour force, which would probably be enormously lessened if more money were spent on the coolies who are already on the gardens. The question is perhaps one which can only be authoritatively settled by professional planters, but the suggestion is one which we think it behoves them to consider. We suggest that the ultimate effect of the labour law is to increase the expense of importation, and that the money would be better spent in observing the coolies who are now in Assam than in paying *arkatis* and contractors in Madras, the North-Western Provinces and Chota Nagpur for locking for fresh labour. We are aware that large sums of money are spent on lines, wells, hospitals. But what the coolie likes is good wages. To higher wages Assam must come at last: even railway communication will not avert that necessity. At present enormous sums are spent on importing labour, and other sums of which we have no account are spent on maintaining useless and unprofitable hands. Could

not a portion of this be diverted to stop the drain of seasoned and time-expired labour? We have not gone into details: we have drawn our figures from the published official reports, our arguments from an impartial and uninterested consideration of the Government statistics. Planters will be able to apply detailed criticism of our conclusions.—*Pioneer*.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Dec. 9.

QUININE.—No further transactions are reported today at the auctions, 3,000 oz. Brunswick quinine in tins were offered. No one was heard to bid, except the broker himself. He declared loudly, amid some laughter, that the lot was sold at 9d per oz.

London, Dec. 10.

QUININE.—Remains in an exceedingly dull condition. For German brands in bulk 9d per oz is still the nearest quotation, and we hear of small sales (about 2,000 oz.) at that figure this week. "It may interest you to know," writes a New York correspondent, "that quinine is in a very bad way here. A well-known London dealer has been sending one of the German brands here on consignment (40,000 oz), and is selling it for any price it will bring. Nobody appears to know what his object is, but we think that he wants to get rid of the stuff at any price, as the market is going lower, and he cannot sell it in London. The price he is selling at today nets him the parity of 8½d, less 5 per cent in London. That is, if we bought at 8½d, less 5 per cent f.o.b. London, and sold here at 18c, less 1 per cent usual New York terms, we would come out even."

THE PERUVIAN MINING INDUSTRY is likely to receive a filip by the important discovery made by Don Pedro Felix Remy, an eminent mineralogist of Lima, and Mr. H. Guillaume, the Consul-General for Peru at Southampton, has done well in calling attention to the same in the English papers. A large number of silver mines in Peru have hitherto been unproductive by reason of the silver ores being mixed with zinc, keowa as the "blende," but Dr. Remy has discovered a method by which the silver can be extracted from these ores, with the result that mines which have hitherto been looked upon as worthless are now likely to turn out most valuable properties.—*Colonies and India*.

COCA-PRODUCTION IN JAVA.—According to a recent report of the director of the Botanical Gardens at Buitenzorg the experimental cultivation of *Erythroxylon bolivianum* has been entirely abandoned there. The influence of light, of manuring and of trimming upon the cocaine percentage of the leaves is now being studied at the gardens, but the experiments are not yet sufficiently advanced to enable conclusions to be drawn from them. So far it can only be stated that the experience at Buitenzorg fully corroborates the conclusion arrived at by Messrs. Zimmer & Co., of Frankfurt, that the new leaves, just developed, are far richer in cocaine than the older leaves. According to Van Romberg the percentage is from 2.3 to 2.4 in the former and from 0.7 to 1.75 in the latter. But *Erythroxylon bolivianum* only contains 0.55 per cent cocaine. Investigations (fruitless so far) are also being made to find a simple method for the preparation of cocaine.—*Chemist and Druggist*, Dec. 12th.

HOW TO SEND FLOWERS BY MAIL.—Cut them early in the morning and let them stand in water some hours before packing, so as to absorb moisture enough to prevent them withering, in which case they will not need to be sprinkled after they are in the box. Pack in a light wooden box lined with cotton batting and covered with tissue paper. Lay the flowers not on top of each other, but in rows side by side, the blossoms of each row on the stems of their neighbours and as close as possible; cover with paper and cotton; see that the lid of the box is secure fastened, and remember to write on one corner "Cut Flowers," as that will insure the package being carefully and quickly handled.—*Harper's Young People*.

CONSUMPTION OF TEA AND COFFEE IN THE UNITED STATES.

There would seem to be little doubt that the proximity to the United States of the greatest coffee-producing country in the world, Brazil, must have strongly influenced the national taste, which leads to a consumption of the berry in the States represented by figures equal to over 7-fold those which stand for tea. The consumption per capita of tea was 1.39 lb. in 1880; it rose to 1.54 lb. in the following year, went down to 1.09 lb. in 1884, rose again to 1.49 lb. in 1887, and sank to 1.32 lb. in 1891. Tea has, in truth, risen only from an average consumption of about 75 millions of pounds in the first three years of the series to about 81 millions in the last three, in the face of a large increase of population. A taste for tea has, therefore, to be revived as well as created in the United States, and there may be, in favour of such efforts during the Chicago Exhibition, a deficient supply of coffee from Brazil in consequence of political troubles. As matters stand the history of coffee in the dozen years presents the most marked contrast to that of tea. The total consumption has risen from less than 440 millions to 511 millions of pounds. There have been fluctuations in the consumption per head as prices advanced or receded, from 8.78 lb. up to 9.61 lb. and down to 8.24 lb. The latter is the figure for 1891 against 1.32 lb. only, for tea, so that the consumption of coffee is now in the United States very nearly eight times that of tea, while of the tea consumed, only a mere fractional part is the growth of Ceylon. In the United States alone, therefore, apart from other portions of America, there is ample room for the exercise of all the energy which can be exercised by the representative of Ceylon and his assistants at the Chicago World's Fair.—The following are the figures we have been analysing:—

IMPORTS OF TEA.

Year.	Net imports. Pounds.	Value. Dollars.	Per capita populat'n. Pounds.
1880	69,894,769	18,983,368	1.39
1881	19,130,849	20,225,418	1.54
1882	77,191,060	18,975,046	1.47
1883	69,597,945	16,278,894	1.30
1884	60,061,944	12,313,200	1.09
1885	66,374,365	13,135,782	1.18
1886	78,873,151	15,485,265	1.37
1887	87,481,186	16,365,633	1.49
1888	83,944,547	13,154,171	1.40
1889	79,192,253	12,561,812	1.28
1890	83,494,956	12,219,643	1.33
1891	82,395,924	13,639,785	1.32

IMPORTS OF COFFEE

Year.	Net Imports. Pounds.	Value. Dollars.	Per Capita Populat'n.
1880...	440,128,838	59,416,196	8.78
1881...	423,276,472	52,368,833	8.25
1882...	435,579,289	42,815,027	8.30

DENDROCALAMUS GIGANTEUS.

One of the fine clumps of this noble bambu is now in flower on Abbotsford estate on the border of the Dimbulandaoaya at an elevation of 4,650 ft. The original stock was obtained from Peradeniya from old Mr. Thwaites in 1874, seventeen years

ago, and the stems are now from 80 to 100 ft. high, and have for several years past supplied capital spouting, fencing, and roof tiles. The flowering clump is exactly opposite the new factory in course of erection, and this is considered to be an exceedingly lucky omen by the natives. So mote it be! *Floreat Cha*, not literally, but symbolically.

CEYLON TEA IN RUSSIA.

Planters' Association, Secretary's Office, Kandy, 26th Dec. 1891.

SIR.—I beg to enclose copy of letter from Mr. M. Rogivue, Moscow, transmitting his report, together with accounts, with reference to his mission to Russia to make known and push the sale of Ceylon Tea in that Empire.—I am, sir, yours faithfully,

A. PHILIP, Secretary to the Planters' Association of Ceylon.

TEA FUND, Moscow, 18/30th Nov. 1891.

A. Philip, Esq., Secretary to the Planters' Association, Kandy.

Dear Sir,—I have duly received your two favours of the 21st and 24th June last, the contents of which had my best attention, with my sincere thanks to the Tea Fund Committee for their last grant of £250 which I received in order through Mr. Wm. Martiu Leake in London.

By this opportunity I have now the pleasure to hand you my report of operations in Russia with account up to 31st October last, showing receipts and expenditure in connection with my work; also extracts of letters and publications referring to Ceylon Tea.

I also beg to advise the despatch by this same post of a packet addressed to you "Registered" containing 8 photos of my provinces, placards and other papers which may prove of some interest to the members of the Tea Fund.

Would you perhaps kindly recommend to your Committee that one of the Overland Ceylon newspapers should be sent regularly to me, the receipt of which would prove sometimes of the greatest interest to my clients interested in Ceylon matters, and at any rate very agreeable to me.

Apologizing to your Committee for the delay in sending report and accounts,—I remain, dear sir, yours faithfully,

(Signed) M. ROGIVUE, Moscow, November 1891. Maroseika, House Lebedieff.

Report to the Ceylon Planters' Association "Tea Fund."

Introduction of Ceylon Tea into Russia.

Gentlemen of the Tea Fund Committee,—Since my last report of the 13/35th April, my occupations have been so numerous and my work so absorbing, that I could not possibly sooner find time to give it a continuation.

Up to that date, I already had sold in Moscow and the Province:—

220 f. $\frac{1}{2}$ Russian lb. of tea in retail (packets only) and 3,500 do do wholesale (packets and cases).

I have since imported to Odessa on firm orders 80 chests (about 8,500 Russian lb. (of an ordinary Pekoe Souehong, which quality is likely to take well amongst the common classes in the Caucasus and the Astrakau Governments, and up to 31st October I sold from my Moscow stock, reworked almost monthly:—

9,142 Russian lb. of tea in retail (packets only) and 11,257 do do wholesale (packets and cases) of which 5,500 Russian lb. in Nijini-Novgorod alone, when I had a Mezazioo during the whole time of the fair (from the 20th July to 10th September) and the rest in Moscow and the Province, the latter extending to the Orel, Witebsk, Woronesk, Tambou, Hursk, Kief, Karkoff, Riazan, Saratoff,

Riga, etc. Governments where this tea is now mostly known, drunk pure and appreciated by thousands of people.

I have agents in all the abovenamed Governmen's, and Depôts for the sale of Ceylon Tea—on commission or otherwise—are permanently opened in everyone of their principal towns. In Nijini-Novgorod, after the fair at the special request of the general public, I have also opened, on my own account, a retail-wholesale Magazine where I have sold from the 12th September up to 31st October an average of 250 lb per week, which I consider as being a very good beginning, very encouraging for the future, making me hopeful of doing there before long a considerable business, this Government being the centre of tea operations and the very one from and for in which a new article has to be introduced into Russia.

A fact, however, worthy of notice is that St. Petersburg and its Government has been, up to date, rather more difficult to convince; the public seems to be there more conservative as regards their taste for tea, and this field would thus require to be especially worked with extensive reclaim and large sacrifices.

Out of the 42,000 lb. of tea I have imported into Russia up to date, the quantity sold in retail (packets) as shown above, since the opening of my business was all for the general consumption, viz: the sorts from Rb. 1-60 to Rb. 3, to the better public and the tea from Rb 1-20 to Rb 1-50 to the lower classes, workmen, peasants, etc. The wholesales (part in packets and part in cases) about 15,000 lb. were made mostly to dealers and Tractors (Public houses).

The Moscow wholesale and retail merchants, large firms like Wogan & Co., K. and S. Popoff & Co., Goubkine, Rastargonieff, Bohkino, etc., have, I am sorry to notice, not begun yet to buy from me, and this for the only reason that they are all against me on account of my having opened magazines for the sale in retail of pure Ceylon Tea, thus setting in competition with them against their rubbish "Chinese" and for mixtures of "Ceylon and Chinese," but now they import largely Ceylon kinds from London,* used here for blending purposes, and it is an indisputable fact, the accompanying extracts of a letter from Mr. Seaton, ex-Asam tea planter, who interested himself so much in the welfare of the introduction of Ceylon and India Teas in Russia and who was here, last year with me, will testify it, that since I am here the export of "Ceylon tea" from London to Russia has considerably increased. I wish I could furnish statistics of import in Russia, but these are very difficult to procure here; it would be easier to get statistics in London of the exports to Russia.

Smaller houses have often bought my tea in quantities of 10 to 15 cases at a time; also for the blending of Chinese. This is done now so largely and in such proportions for "Ceylon" that all these firms are damaging their names as well as their marks for good Chinese, thus likely without seeing it, accustomed by degree the Russian public to the taste of "Ceylon" and therefore helping me greatly and serving considerably our cause and interests. This also will be testified by the letter (translation attached) of a Karkoff Russian merchant, who takes the greatest interest in the Ceylon staple.

REGARDING PRICES.—Six months ago, when the sterling exchange was at Rb. 8-50 per £ st. and the gold agio (duty is always paid in gold) relatively low about 35 o/o, a tea costing in London 10l. could be laid down in Moscow at Rb. 1-10 kop. Russian lb. duty paid, now that the exchange has gone to over Rb. 10-50 per £ st. and the agio is fluctuating up to 73 o/o, the very same tea turns up to Rb. 1-50 kop., duty paid, in Moscow, a difference of fully 40 o/o. The above prices for "Ceylon" compared with the prices for "Chinese" are in favour of the former, because notwithstanding their purity and economy, it is now ascertained by many that a Ceylon Tea sold here at say Rb. 2 per lb. is of far better quality than any

mixture of Chinese and Ceylon sold at same price; I have been often told that my pure Ceylon at say Rb. 160 per lb. is of much better quality than tea at Rb. 2 from Popoff, Tillipoff or other retailers.

RECLAME.—This, as I have already pointed out, is the "key" to the success, the "main hinge" in the enterprise. To push an article, to introduce a new product, reclaim and advertisements are absolutely necessary: it is the same in every country of the world; and in Russia when, I may say, this is carried by all on a very large and extensive scale—perfectly well understood enormous sums being given away for this purpose—it ought certainly to be done especially when the object in question is to change the taste of thousands of people accustomed to an article solely known by them which never had a like one to compete with. For Ceylon tea it is not thousands, but many thousands of Roubles which ought to be spent now—after its introduction—for its extension all over this country, and I wish I could do as much as the enterprising American merchant who is now spending a sum of 40,000 Dollars in the reclaim for Ceylon tea in the United States, as will be shown by the interesting article published recently in the "Pyckoe Odezprine" Russian Review, of which I attach herewith a translation.

I annex accounts showing first expenditure made in trying to attain these ends, and I will draw again the attention of your Committee on the necessity of much more funds to be sacrificed in order to continue the work and obtain the desired results, as it must be well understood that although some progress has evidently been made, much more remains to be done before Russia gets its tea supplies direct and regularly from Ceylon.

After having preliminarily advertised in newspapers and by other different means, my reclaim began with the opening of my magazine (Maroselka, House Lebedieff) of which the accompanying photos perhaps will prove of some interest in Ceylon, in order to give the public the possibility of buying this tea in packets and drink it pure. Placards, price-currents, fly-bills, reclaim, books, etc. (as per accompanying specimen) have been printed and distributed abundantly all over the country and especially in the Kiosk opened at the French Exhibition in Moscow where tea in packets and in one was sold and presented to the public during five months.

In a commercial point of view this Kiosk was a complete failure, Rb. 2,000 and more have been dropped, but it was and is still very noticeable that it did a great deal of good as well in Moscow as in the province, the sale having thus much increased. Another reclaim of great weight was the Nijini Novgorod Fair about which I have already written above; there I may say, selling tea in packets of ½ lb. ¾ lb and 1 lb. I have given to many thousands of people of all classes and of almost all parts of the country, the means of tasting the pure and genuine article and I do not think it is dishonest of myself to predict for the next Fair there, a very considerable business, if I am in a position to bring on that market the necessary quantity of tea to do it. If calculate that about 50,000 lb. could easily be sold there (retail and wholesale) during the forty days the Fair lasts.

PAID AGENTS were also engaged by me to visit Moscow and the Province, offering my tea in private houses, restaurants, hotels, tractors, etc. in fact in every place where tea is drunk, and the result was that many of these have been gained to the cause of Ceylon tea and became my regular customers, as they very soon found out the great and indisputable economy in using it. Many, however, are still reluctant to its peculiar taste compared with "Chinese" and it will require a great deal more work of per-

* Mr. Rogivue evidently wrote the name in Russian. "Pyckoe" should be "Rusky." "Odezprine" is beyond us.—Ed. T. A.

† Mr. Rogivue meant to say "boastful."—Ed. T. A.

* Which the figures for exports from Britain to Russia do not seem to bear out.—Ed. T. A.

anxious to convince them that this beverage is drinkable!

ADVERTISEMENTS in the press has also been used by me on a moderate scale and proportioned to my means as the medium of reclame. This is no doubt a very expensive item when done properly, but would be of great help for our success, and if I could, by some intelligent sacrifices, present generous entertainments, liberalities of champagne such like extravagancies gain the hearts of the reduction of our best newspapers and induce them to write now and then some favourable articles on Ceylon and Ceylon products, Tea especially. We would undoubtedly carry the cause before long. There are many other ways of doing good reclame, but even when done judiciously it requires much larger sacrifices of money than I can afford.

REGARDING BUSINESS IN GENERAL.—As your Committee is aware I, backed up by a firm in London have established myself in Moscow as part proprietor and manager of the "Ceylon Tea and Produce Agency of Russia," selling in my Magazine Tea, Coffee, and Cinnamon, also Cocoa, of which I have small stocks, and other articles (only Ceylon) on commission. The business so far, proportioned to my modest capital about £st. 2,000 has shown pretty well satisfactory to enable me, with the aid of your funds, to cover expenses and to get now convinced that it is well done on a more important scale, with a larger capital sufficient to conduct a well advertised reclame and to permit the import of larger invoices of tea leaving ready money at disposal for the clearance of duty whenever required, such a business would prove before long a well paying and lucrative concern. My capital is evidently not large enough to give the enterprise the desired rapid and noticeable progress or extension; I missed the sale—on this and the Nijini—markets—of many hundred chests of tea for the want of above-mentioned conveniences and this, I must say, rather impressed against me the public who at first expected to find in the Commissioner of the Ceylon P. A. Tea Fund for Russia representative of a large commercial company able and prepared to invest millions in such an important enterprise.

IN RUSSIA most of the business are done on credit allowing to purchasers up to 9 and even 12 months' terms; my retail sales are all for ready money. At the opening of my business, I have, however been obliged to give also credit to some extent in order to facilitate the introduction of our tea, but, although I have been lucky enough not to lose anything of importance, now that the circumstances are getting so critical and business so difficult by bad crops, famine, etc. all over Russia. I have established my business on the safe basis of the strictest cash conditions which were, of course, somewhat troublesome at the beginning, but to which the amateurs of pure Ceylon tea must now submit.

Resuming the foregoing, I may safely say that Ceylon tea is now partly introduced into Russia, sold, drunk and appreciated as pure to and by a great number of people of all classes and that it only requires for the extension, the development of its import and sale all over the country, a well established enterprise, with a sufficient capital capable of importing large quantities to be distributed on the principal Russian markets, of clearing duty on whatever quantity required at a time, of opening magazines for the sale of tea in retail and wholesale in all the principal towns of this great Empire and of advertising on an extensive scale and well conducted manner, especially through the press.

From the above figures it will be seen that out of the 42,000 lb. Ceylon tea I have up to date imported to Russia, 34,000 lb. have been already sold with an increase of about 3,400 lb. per month for the last six months from 1st of May to 31st October. As pointed out I could have much exceeded these figures, and it is my firm belief that out of the about 70 millions lb of tea yearly consumed in Russia one-fourth could—why not?—become Ceylon tea before five years have elapsed, if its import were properly pushed forward the more when considering that Chinese qualities

are visibly decreasing gradually.

I still would strongly impress upon all the Ceylon planters the necessity of their tea packages being of better make and in stronger condition; also more evenly tared in order to prevent further complaints on these respects.

And should the business take the desired and expected proportions, I would recommend as an important and indispensable factor the establishment of a purchasing forwarding agency with blending store in Colombo.

It remains to me, gentlemen, in submitting the accompanying accounts to the examination of your Committee to beg for the continuation of their support in the welfare of an enterprise, which has now so entirely taken possession of me, that it is my sole object to bring it to an end,* and trusting your Committee will understand that my not having finished sooner and more frequently reports of my doings was only due to want of time.—I beg to remain, gentlemen, &c.,
(Signed) M. ROGIVUE.

(Appendix to Mr. Rogivue's Report.)

TRANSLATION.

Mr. M. Rogivue, Moscow.

Dear Sir,—After having bought from you a small lot of Ceylon Tea, I sold it with the greatest care directly to consumers whereby I had the opportunity to get the opinion of several and to convince myself of its superiority over China Tea.

The consumers immediately appreciated the strength of its infusion and its fine colour and generally praised the agreeable, though perhaps somewhat peculiar taste to which they however soon get accustomed.

Lately many large firms began to mix Ceylon Tea to China, therewith accestomg the public by degrees to the taste of Ceylon Tea. For this reason the consumers buy willingly pure Ceylon Tea with preference to Chinese on account of its economy and strength.

For the extension of this article it is necessary to open here a special magazine under your own firm. I am thoroughly convinced that the sale of Ceylon Tea would be successful as well in retail as by wholesale if you would give the buyers convenient discount and credit. With energetic work and good management of the business it would be easy to gain in a short time a great many purchasers.

Many people who bought from me your Ceylon tea now refuse to return to Chinese and this is a guarantee to me that by proper dealing in this special business this article would soon make its way amongst the public. According to above mentioned advantages I would propose the opening here of a nicely put up, well fitted small magazine which management I am willing to take under certain conditions.

Karkoff, the centre of business for the South of Russia, has six yearly fairs visited by numerous merchants which makes this place the most favourable for the introduction of this article.

All the important tea firms like K. S. Popoff, Kostorgujew Khinouchine, Wogan etc. have here large stores and magazines.

If you are willing to give me for some years the management of this business, within a limited radius, I would be ready to come over to Moscow in order to arrange matters with you.—Waiting your reply, I remain etc.

(Sign.) F. ASSMAN.

Karkoff, Oct. 24th.

Extract of an article in the *Pyechoe Odozporrio* (Russian Review.)

The Ceylon tea, worthy of the highest praise for all its good and predominant qualities, is now exported in considerable quantity to England. As a proof of the progress it is making in the trade we give the following figures:—

Export from 1st Oct. 83 to 13th June 84—	263,464 lb.
do do 1st do 84 to 13th do 85—	461,559 "
do do 1st do 85 to 13th do 86—	106,2302 "
do do 1st do 86 to 13th do 87—	188,4307 "

which show that during these four years the export of this article increased eightfold. Stimulated by these rapid progress, the Ceylon Planters decided to avail themselves of the American markets and lately made a first attempt by shipping to the United States 6,000 lb. of Ceylon tea. For its Reclame alone an enterprising yankee had the boldness to spend 40,000 dollars.

NOTES ON PRODUCE AND FINANCE.

LAST WEEK'S TEA SALES.—Importers have shown less disposition to over-supply the market with Indian tea, and consequently the quantity brought forward has been smaller than of late, says the *Produce Markets Review*. Now that there are indications of a falling-off in the demand, owners will best study their interest by not forcing their tea on unwilling buyers for the next few weeks. Although the enquiry has not been so active, a fair business has been transacted at generally steady prices. The figures for the past month, compared with those of last year, are on the whole satisfactory. The imports

show an increase of upwards of 400,000 lb., namely 18,870,000 lb. against 14,526,000 lb., and the delivery 10,051,000 lb., as compared with 9,606,000 lb. The stock shows a considerable augmentation, being 4,380,000 lb., against 30,977,000 lb. last year, and this is attributable to the heavier imports, which have reached the large total of 62,300,000 lb. for the past five months, against 53,100,000 lb. in the same period in 1890. At the public sales 41,000 packages were offered, 4,000 of which were withdrawn. In Ceylon teas an unimportant increase in the quantity of tea offered has been followed by a very slight fall in the price of common descriptions. Good teas, however, whether leafy or broken, have firmly maintained the late rise in value, and a few breaks of extra quality fetched very high rates. The general demand continues good. The most striking fact connected with the London stock returns for the past month, says the *Grocer*, is that the landings of India tea have reached 18,870,000 lb. which supply was 4,343,500 lb. heavier than in the same period last year. It was therefore a matter of comparatively little importance that the deliveries during Nov. were 10,042,000 lb., or 434,850 lb. larger than in 1890, as the addition to the quantity on hand was naturally very considerable, and the amount held in the bonded warehouses on the 30th ult. embraced 40,362,300 lb., or 9,384,750 lb. more than at that date in the previous year. In the quantity pressing forward by auction little curtailment has been noticed, the week's assortment having presented a total of 40,420 packages, which have again greatly tried the capabilities of the trade in tasting and valuing, to say nothing of the exhausting efforts of bidding and recording bids in the public sale-room, and as a larger proportion of these supplies than ever seems to consist of low, common and medium qualities, they have gone off at very cheap rates, especially for teas under 9d per lb., so that many persons are beginning to ask themselves whether the lowest point of the season has not been reached. On most grades there is a decline of 2d per lb. from the best rates of about two months ago, and should the eagerness to realise abate such teas as the above would probably be soon snapped up at a smart reaction. For other and the finer kinds the demand has been steady without being particularly active, and the market at the close has a healthy, though rather quiet, aspect.

THE MANUFACTURE OF IMITATION COFFEE.—According to a paper by G. L. Spence and E. E. Ewell, of the American Association, wheat flour and bran mixed with molasses seem to be the favorite materials for the manufacture of imitation coffees. The manufacturer never selects a good quality of flour, since a bad or damaged article answers equally well, besides being cheaper. Refuse bisuits and the waste products of bakeries also supply a portion of the material employed. A factory was recently seized in France, when it was discovered that "coffee" was being made out of a mixture consisting of 500 parts of sulphate of iron, 15,000 parts of chicory, and 35,000 parts of flour. Such a mixture as this cannot but be detrimental to the health of the consumer. But most of the artificial "coffees" consist of less harmful ingredients, which, however, if they do not affect the health specially, affect the purse of the purchaser.

BILLS OF LADING AND THE EASTERN TRADE.—In a letter signed by Messrs. Henderson Bros., for Anchor Line; Messrs. Robert Alexander & Co., for Hall Line; and Messrs. Cayzer, Irvine, & Co., for Olan Line, the writer says:—"Referring to the remarks that have appeared in your paper, in connection with a clause in some bills of lading giving the shipowner a lien on the goods for freights, charges, debts, &c., other than those properly appertaining to the goods mentioned therein, we beg to inform you that the bill of lading in use by our respective firms in the eastern trade was agreed with the Manchester Chamber of Commerce in 1887, and does not contain the objectionable clause referred to. Owing to the numerous letters we have received on the subject we will thank you to give the necessary publicity to this letter."

IN BOND.—According to the B Bill of Entry, the quantity of tea remaining in the Customs and Excise warehouses of the United Kingdom on Nov. 30 was 100,685,155 lb., against 91,642,845 lb. a year ago, and 105,894,016 lb. at end of November, 1889; the stock of coffee being 104,247 cwt., against 163,350 and 291,715 cwt.; of cocoa, 11,625,859 lb., against 10,146,099 and 10,923,709 lb.—*II. and C. Mail*, Dec. 11th.

CATTLE KEEPING AND DAIRYING IN INDIA.

"Cow-keeping in India" is truthfully described on the title-page as a simple and practical book. The author of the work is *ISA TWEED*, who having undertaken the management of milch cows for no less than eighteen years, and the medical treatment of cattle for a considerable period, embodies the results of the experience thus obtained in a volume which is a valuable contribution to agricultural literature of the East.

In a preface to the book the author states that personal care and supervision, and the strictest attention to details are absolutely essential in the successful management of cattle; and it cannot be denied that whatever the excellencies of the natives of Ceylon they can as little be trusted to faithfully carrying out the details of a system based on sound sanitary and economic principles as their brethren on the neighbouring continent.

The following are the headings of the chapters into which Book I is divided:—Advantages of Keeping Cows; Breeds of Cattle; Buying Cows; Points in a Good Cow; Food; House and Utensils; Attendants; Washing, Grooming, and Exercise; Breeding; Bulls; Bullocks; Dry Cows; Management of Cows when Calving; Calves, their Value, Management and House; Points in a Good Calf; Castrating Calves; Taking the Bull; Barren Cows; Age of Cattle; Price of Cattle; Milk; Cream; Butter; Ghee; Curd and Tyer; Lice, Ticks, Flies &c.; the Seasons of the Year; Cattle-dung; and Grass-lands. Cow-keeping is called "a profitable pastime," the profits arising from the sale not only of milk, butter and ghee, but also of calves and dung. At the outset we are advised to select good specimens from good breeds, as being more satisfactory and more profitable to keep. The breeds given as the five principal ones in India are the Hansi or Hissar, Nagouri, Nellore, Guzerati and Googaira, but other less distinct and important families are also referred to. Though English cattle do fairly well in cool climates in the East, they are as a whole put down as "troublesome and costly business." It is recommended that for milk thoroughbred Hissar, Nellore, Guzerati or Googaira cows should be kept, or else good crossbreds of the second crossing between the cows of the country and the bulls of pure blood.

On the subject of improving the breed of cattle of a district the author thinks that the Government should take up the matter, and import good Hissar bulls into every district. Every village or group of villages should be induced to purchase and keep a bull, and the people should be encouraged to improve their cattle by the offer of prizes for the best specimens, bred by them and by the holding of cattle shows. It is also suggested that the villagers should be made to pay something towards the purchase and keep of the bull, as they will then take a greater interest in the animal, and will take care of it. The bull should be put in the care of the headman of the village, and he should be

responsible to the magistrate for its proper treatment. "If this plan be adopted throughout Bengal," says the writer, "in five years there would be very marked improvement in the cattle." This is a scheme which with very few alterations might well be adopted in Ceylon; and to judge from the steps taken by the School of Agriculture, and the utterances of His Excellency the Governor in November last, it is not improbable that the Government contemplates taking active measures for the improvement of our native breed of cattle.

Our author classes milk under three headings:—(1) Yellow creamy milk which contains a large proportion of fatty substance necessary for butter; (2) Thick heavy white milk which contains a great deal of case in suitable for cheese, junketa, curds, &c.; (3) Thin bluish milk which is sweet and nice but does not produce much butter, cream or curd. The last, which is the most common kind of milk produced by Indian cows, is said to be the best for children and invalids. The lactometer is justly condemned as unreliable since it does not furnish any absolute standard of purity. The solids of milk are heavier than water, but the fat (butter) is lighter, and very rich milk may rank lower, as shown by the lactometer test, than milk; that is really poor in quality. If sugar is added to watered milk the lactometer will show it as pure milk; and again the pure thin bluish milk will by the same test rank as watered milk. It will be well for housewives and stewards of hospitals, asylums and such institutions to ponder over this explanation, as milkmen even in Ceylon are up to the trick of doctoring milk for the lactometer test. In Colombo buffalo milk, coconut "milk," sugar and water are all used to bring up milk (supplied to Government institutions forsooth) to the required standard. For keeping milk good the best kind of vessels are said to be well tinued copper pans and vessels made of zinc, bell metal, or wood. China crockery is objected to as retaining heat, and silver or metal vessels and spoons are also to be avoided. Vanilla is said to have a wonderful effect in keeping milk sweet; a drop of its essence being of great help in keeping it good.

With regard to foods we are told that kullai, gram, barley and wheat are the only grains that should be given to milch cows—rice not being particularly nutritious and Indian corn tending to fatten but not to increase the milk yield; green grass is very essential and gives colour and richness to the milk and butter; cotton seed produces rich milk but should be given in moderation; oil cake (gingelly, linseed and coconut) helps to produce milk and butter; bran helps digestion and produces milk. Different mixtures of these ingredients are given as guides to feeding and to each mixture is added a small quantity of salt and sulphur, which are said to be purifiers, keeping the bowels in proper condition and acting as preventatives against many diseases. It will be remembered that the cattle commission appointed some years ago also recommended salt and sulphur as preventatives.

With regard to the amount of land needed for cattle the author comes to the conclusion that good cows cannot thrive on less than one acre. Of this extent four-sevenths should be left in grass, and kullai, gram, or wheat, grown on the remaining three-sevenths. It is insisted that every five years this grass land should be thoroughly ploughed up and cleaned, while manuring should be done at short intervals. The subjects of housing and utensils are carefully explained by the aid of diagrams, and the plans for cattle sheds might well be adopted by those who go in for dairying in Ceylon. The greatest cleanliness is of

course urged. "Keeping the floor clean," says the author, "is an indispensable necessity. It must not only be swept clean morning and evening but be thoroughly scrubbed and washed in the morning and swept every time it is soiled, while the droppings must not be allowed to remain on the floor, or drain, any length of time. The house has kept clean and sweet, and perfectly dry, and phenyle and water or carbolic powder should be sprinkled on the floor every day." This is certainly a very thorough and businesslike way of doing work, but if disease of cattle and through them human beings is to be prevented, such sanitary methods (substituting perhaps some commoner and cheaper means of disinfection) might with advantage be insisted upon by the present Sanitary Department till the contemplated Veterinary Department is founded. For the proper carrying out of such measures as above described it is calculated that six cows—or better, four—should be under the care of one man.

The second part of this useful work deals with diseases of cattle, goats and sheep—common complaints, dangerous but not serious diseases, contagious and fatal disorders. At the outset a list of preliminary rules for the care of animals is given. In a review such as this it is not possible to do more than refer to a few of the useful hints with which the work teems, and cow-keepers in Ceylon—whether they keep cattle for convenience or profit, on a small or a large scale—will not regret the purchase and perusal of Isa Tweed's simple and practical manual, which fully meets their own requirements. The reference to rinderpest (with which our cattle commissioners identified the disease commonly known amongst us as "murrain"), from the fact that it gives, in addition to the ordinary preventative measures as regards diet, disinfection and general management, distinct curative treatment is worthy of quotation:—

In India, treatment is often successful, and this may be attributed to the disease very often appearing in a mild form. Rinderpest belongs to a class of diseases which must run its course; that is, the poisonous material contained in the system must gain exit to allow of the patient recovering. The grand aim of the treatment should be to aid nature in ridding the system of the poisonous matter, and to support the strength of the animal by food ease, nursing and proper diet.

ORDINARY TREATMENT.—Immediately the first symptoms appear give the animal 2 chittacks of Eno's Fruit Salt or 4 chittacks of Epsom or half seer of common salt in warm water, and repeat the dose every hour until the bowels are relieved.

When purging and passing of blood and mucus continues for more than twenty-four hours, give the following draft, which has proved successful in Mr. Thecker's hands:—

Camphers	3	tolah
Nitre	3	tolah
Datura seeds...	4	Kancha
Chiretta	4	tolah
Arrack	2	chittacks

But when the diarrhoea has existed above twenty-four hours, the following, finely powdered, may be added to the preceding prescription:—Gall nut 3 tolah. This should be repeated every 12 hours until the purging ceases. For sheep and goats one-sixth of the above dose should be given.

NATIVE TREATMENT.—Fresh roots of the chichery plant, 4 tolahs fresh roots of the Jokka plant, 4 tolahs; thorns of the shinal tree, four tolahs. Have the whole pounded or ground together and give a dose of twenty grains of this medicine every morning for three days. Ten grains for a dose to a calf, and five grains to a goat or sheep. All natives know the first and last named plant and tree, but jokka is the Santali name for a plant that grows wild in their district.

HOMOEOPATHIC TREATMENT.—As soon as the symptoms are seen, give aconitum nay. lx. and arsenicum alb. lx. ten drops alternately, every three hours; when the eruption appears give antimonium part lx. one grain every three hours. If the eruption is driven in give spirits of camphor ten to twenty drop doses every ten or fifteen minutes, until the skin gets warm and the eruption reappears. Sulphur is very good when the eruption is disappearing and there is great itching &c. . . . When the disease is prevailing in the district, give all your cattle a dose of the native remedy, or else a dose of tincture of sulphur, 20 drops every morning for three days . . . I have found the native and homoeopathic treatment very effective.

CURE FOR HEMILEIA VASTATRIX.

In the struggle against *Hemileia vastatrix* 12 years ago, many heroic steps were taken by planters, but probably none so heroic as those which I myself adopted. Amongst others, one plan I tried was boring a hole right down the centre of the stem of the tree filling the hole with sulphur and plugging it up. The result was that, the first season afterwards, the trees all but died, but the following season they flushed splendidly, bore a remarkably good crop, and apparently showed no signs of leaf disease. What happened afterwards I do not know, as I sailed for England, home and beauty after that season, but the following cutting seems to support the idea which I appear to have originated, and I think it might be worth while trying it as a cure for bug on coffee:—

It has been frequently stated, says the weekly writer on practical gardening operations in the *Leader*, that insects and other fungus pest could be destroyed by boring holes in infested trees and filling them with sulphur. Reports to that effect are frequent in the United States, but there are few who believe in them. We have, however, had a well authenticated statement that an old settler tried the experiment with success on an apple tree badly infested with woolly blight, which presently disappeared and was not seen again, and when, many years after, the tree was cut down a very small portion of the sulphur remained. We do not see why the practice should be laughed at and the beneficial action of the sulphur denied. It being a fact that gases exist in all parts of a tree or other plant, why should not sulphurous acid gas be generated and circulate through every part of a tree in such volume as to poison any insect or fungus that subsisted on the sap?

One would have thought that the sorrows of cinchona growers had got to the lowest stage of depression, but there would appear to be a lower stage still, judging by the following paragraph:—

The Sunflower.—A Russian physician, Dr. Flatoff, is endeavouring to induce the medical world to make a larger use of the sunflower as a drug. It can, he asserts, be advantageously used in place of quinine without having the drawbacks of this excellent medicine. The sunflower is already much used in Turkey and Southern Russia in cases of fever by the common people, who find quinine too expensive.

THE BURMA RICE CROP.—Sixteen annas, the equivalent of a rupee, representing an average crop, a memorandum from the Revenue and Agricultural Department of India, dated Calcutta, the 15th Dec. 1891, gives the estimates for various districts, thus:—

Akyah eighteen annas, Bassin, Thongwa, Aulerst, and Shwegyin sixteen annas, Hanthawaddy fifteen annas, Pegu Tharrawaddy, and Prome fourteen annas, Henzada twelve annas. It is estimated that there will be available for export 1,210,000 tons of cargo rice equivalent to 20,508,500 wts. of cleaned rice, including what is required for Upper Burma.

DECAY SPOTS UPON LEAVES.—Plants with large leaves are often much disfigured by blotches that appear at any place upon the foliage. The cause of these spots is sometimes not easy to determine. An otherwise perfectly healthy Calla-leaf may have a brown spot an inch long and a half-inch wide near its centre, and with no apparent reason for its existence. The probabilities are, however, that some days before a withered blossom of a plant above it fell upon the leaf, and, remaining there for a time, began to decay. Soon after, the force of the water from the hose drove the blossom off, but not until it had left the seeds of decay in the leaf. In other words, the fungus, usually a species of *Botrytis*, while flourishing upon the rich succulent substance of the blossom, sent its threads into the leaf below and began the decay that finally ruined the leaf. The *Botrytis* fungus is not usually accused of making its attacks in a direct manner upon living tissue, but it does not hesitate to pass from the dead to the living when conditions favor it. In other words, the Calla-leaf is safe against the attack of the spores of the *Botrytis*, but when the vigorous filaments of well established plants present themselves the resisting power is not sufficient to overcome them. If we had found the remains of the blossom in the centre of the dead blotch it would have been natural to ascribe the cause to the flower or the fungus it harbored, but in many instances the leaf blackens without any apparent cause. Nevertheless the cause remains the same, for the source of contamination had been removed before the decay in the leaf had become perceptible. The practical conclusion is, that no opportunity be given these half-way parasitic fungi to gain an entrance to healthy plants. The gardener knows how important it is to keep all dead leaves and decaying blossoms from contact with the healthy parts. Neatness as well as health demands that the living be kept part from the dead.—*Garden and Forest.*

TAKING TEA WITH A LAMA IN MONGOLIA.—forms the subject of a half-page illustration in the "Illustrated London News" of 12th Dec., by its special artist, Mr. Julius M. Price, who thus describes the ordeal:—

At one of the places where we halted, I had a rather envious experience of the Mongolian style of taking tea. Accompanied by one of the Cossacks, who spoke the language of this country, I visited a Mongol who was rather a swell in his way, for his "yourt," which I had been anxious to see, was fitted up with some pretensions to style. We seated ourselves in the usual manner on the ground, and our host, after a few minutes, of course offered us the inevitable tea. This was what I wanted particularly to avoid; but there was no getting out of it this time. A particularly unwholesome, old-looking hag then divd into the gloomy recesses of a sort of cupboard, and produced three wooden bowls, containing some greasy-looking compound, which she forthwith proceeded to clean out with her grimy fingers, finishing up by polishing vigorously with the tail-end of her gown. These tasty receptacles were then placed before us on the ground and were filled with some vile liquid, which bore no resemblance to the "cup that cheers but not inebriates." However, it would have been an insult to the man to have refused his hospitality; so for the next five minutes I was racking my brain how to get out of even sipping his awful stuff. My companion, who was used to Mongolian customs, was not so delicate in his tastes, and managed to get through his bowl all right, at the same time advising me to try and do likewise with mine, so as not to offend the man. Providentially, however, at this moment someone came to the door of the "yourt" to speak to our host, and we all got up. I immediately took advantage of the opportunity quietly to empty the contents of my bowl into a dark corner near me. We shortly after took our leave, in spite of the old Mongol's pressing invitation to stay and have a drop more tea. When we got outside the "yourt," my companion, who had not noticed my manoeuvre but had observed the empty bowl, remarked that he knew I would like Mongolian tea if I once tried it!

Some time last year a native gentleman in Mysore sent Mr. D. Hooper, the Government Quinologist, a sample of prepared tea made from the leaves of a kind of *jumbal* for examination and opinion as to its effects if used constantly as a beverage. The leaves were identified by Mr. Lawton, the Government Botanist, as those of *Eugenia caryophylla*, a myrtaceous shrub, which contained a little tannin and gallic acids, colouring matter, essential oil and ash, but no stimulating constituent, such as the alkaloid caffeine found in tea and coffee. Mr. Hooper thinks the beverage would be an innocent one, and not likely to affect the system either in health or disease.—*Madras Mail*, Dec. 30.

PRESERVED PINEAPPLES.—We recently quoted a paragraph from the *Straits Times* stating that the pineapple preserving industry in Singapore has been so much developed and the demand from Europe is so great that the price for fresh pineapple has risen to \$4 (about 16s.) per hundred, and that even at this enhanced rate the local demand cannot be supplied, and those engaged in the industry find it necessary to scour the adjacent islands and territories in order to keep their factories going. Is there any reason why the industry of preserving pineapples should not be equally successful in Ceylon as in Singapore? It may be that the presence of Chinese gardeners in Singapore makes all the difference.

ORANGE CULTIVATION IN NORTH-WESTERN INDIA is receiving much attention, as the following extract from the Report on the Saharunpore Gardens, will prove:—

Oranges.—The plantation of these made in the year 1887 is in a healthy and thriving condition, and several of the new varieties fruited last season for the first time. One of the best of these new kinds was a variety received from China in 1887, under the name of Sz-ju-Kom. The fruit was something like the common mandarine orange in outward appearance, but it was more juicy and of richer flavour. The variety is a desirable one, and is being extensively propagated for distribution. Seedlings of a variety called the Butwal orange of Nepal received in 1886 from Dr. Bonavia, late of Etawah, also fruited for the first time. The fruit of this kind was very like that of the common cintra or suntra, only smaller, but the flavour was the same. I should say this is simply a variety of the cintra, and not sufficiently distinct to claim another name. A seedling Malta orange raised from seed grown in this garden and sown in 1885 also fruited. The outward appearance of the fruit was very like that of the common Malta, but when cut it showed a blaker skin, and the pulp, instead of being sweet, was intensely bitter. The seed was undoubtedly taken from a sweet fruited variety of Malta orange; therefore, this is an authentic case of a seed from a sweet form of orange having produced a form with bitter fruit. In the same row there are ten more trees raised from the same batch of seed, but these have not fruited yet. When they do, it will be interesting to note whether any more bitter varieties appear among them. The following varieties of oranges were kindly presented to the garden by Mr. R. D. Hoyte, Bay View, Nurseries, Florida, United States, America. The collection as despatched numbered eighteen varieties, but eight perished in transit:—Hart's Late, Star Calyx, (Oban Madarine, Satsuma, Malta Oval, Spice Tangerine, Mediterranean Sweet, Lahita, Queen and Washington Naval. Five plants of each of the following varieties were imported from Japan:—Finger, Satsuma and King-Kam. All five plants of the "Finger" variety arrived in excellent condition and are doing well; two plants of the "Satsuma" survived the journey and promise to grow; but all the plants of the "King-Kam" perished in transit. In addition to the above oranges from foreign countries, one variety was obtained from Nagpore, eight varieties from Poona, ten from Lahore, and twelve from Lucknow. These together with the foreign sorts, have considerably increased our collection.

NOTES FROM OUR LONDON LETTERS.

MR. ROGIVUE'S MISSION—A SEPARATE ROOM FOR THE SALE OF CEYLON TEA IN MINCING LANE—PALAIS INDIEN CO. AND CEYLON TEA FUND—MR. LOUGH AND CEYLON TEA—CELLULOSE OF COCONUT FIBRE—JOKAI AND JHANSZIE COMPANIES.

LONDON, Dec. 11th.

Before you can receive this will doubtless have had sent you for publication Mr. Rogivue's lengthy report to your Planters' Association on what he has done in introducing Ceylon tea into Russia. He sent a copy of his very voluminous report to the Ceylon Association, but the copy (on copying paper) is almost illegible. We gather, however, that, up to date of his reporting Mr. Rogivue had received about 40,000 lb. of Ceylon tea, of which quantity he had disposed of about 35,000 lb. This does not appear to us a very large amount considering the time his agency has been working; but it would be unfair for us to judge of this without a full reading of what he has written direct to Ceylon.

The question of finding a remedy for the difficulty about the sales of Ceylon tea in Mincing Lane appears likely to find a solution by the beginning of the new year. The brokers are now arranging among themselves and with the proprietors of the sale-rooms to conduct Ceylon sales throughout the whole of Thursdays in a room distinct from that in which the sales of Indian are carried on. If this arrangement can be fully carried out, it will no doubt afford a large measure of relief, though competent opinion informs me that it will not be likely to suffice for your full needs for more than two years at the outside. Meanwhile the brokers have further bestirred themselves to bring their samples into the rooms at an earlier time, so that we do not now hear of the complaints lately made that it was impossible to duly test their quality. It is not known to me whether to effect their earlier showing it has been found to be necessary to somewhat defer sales; but even if this be the case we feel very sure the sellers will find their balance of advantage in the arrangement, and since the more time has been given it is undoubtedly the fact that Ceylon teas have been fetching better relative prices than those of India.

The Sub-Committee that I wrote you had been appointed to negotiate with the directors of the *Palais Indien* Company having had a conference, have submitted a resolution to the effect that it does not think it possible to frame any scheme of co-operation which would be likely to meet with the approval of the Ceylon Tea Fund. They found upon inquiry that the financial position of the company is not without its embarrassments, and the fact would prevent the Tea Fund from subscribing the additional capital which the *Palais Indien* directors desire to raise. Meanwhile, the Sub-Committee report that they consider that company to have done, and to be doing, good work.

In this connection I must tell you that I seem to have somewhat misunderstood Mr. Lough's position with regard to the agency for the disposal of your tea in Paris. It was always my impression that he had accepted that agency quite independently of his association with the *Palais Indien* Company. It has now been pointed out to me that his acceptance of the agency was contingent upon Ceylon subscribing towards the capital of that company. As this is not now likely to be done, all relations between Mr. Lough and the Ceylon Association in London have closed, and if

he sells Ceylon tea in his Paris kiosks it will be only because he finds it is to the taste of his customers, and not in pursuance of any obligation he had contracted with the Association and with your own local bodies. As, however, this latter fact has only just now been established, anything that has been previously written by me with respect to what Mr. Lough said at the meeting of his company would still hold good, as at that time he was certainly recognized as the authorized agent, although the terms of his acceptance of that office had not then been decided upon.

My last letter referred to experiments proceeding at Portsmouth by the Admiralty to test the alleged qualities of cellulose of coconut. Apparently they have gone beyond us in this respect in America, for we see a paragraph in the *Engineer*, which informs us that a large factory, with extensive plant, is being erected in Philadelphia for the manufacture of the article. That journal gives us the additional information that it is exceedingly difficult to make a hole of any kind through this cellulose, and we presume this to mean that on the withdrawal of any piercing or boring tool, the fibre of the cellulose at once closes the hole made. This would certainly be a most valuable quality for the lining of ships, and we hope soon to hear more about this material and how it is prepared, whether from the nut itself or from the fibrous husk. We should naturally assume that it must be from the latter.

The directors of the Jokai (Assam) Tea Company (Limited) have declared the usual interim dividend of 5 per cent per annum on account of the working of season 1891, being 10s per share payable on the 10th instant. Similarly the managing agents of the Jhanzie Tea Association state that the customary interim dividend of 4 per cent per annum, being 4 shillings per share will be paid on account of the 1891 crops on the 10th instant.

CEYLON TEA PLANTATIONS COMPANY AND THE PROPOSED CULTIVATION OF COFFEE IN THE MALAY PENINSULA—THE "GROCER" ON CEYLON TEA.

LONDON, Dec. 18.

The Ceylon Tea Plantations Company is, we hear, intending to commence coffee cultivation in the Malay Peninsula. You will be aware that the Company's manager in Ceylon, Mr. G. A. Talbot, visited the Peninsula as late as last October, in order to report on the prospects that would lie before such an enterprise. Consequent upon that gentleman's report, the directors of the Ceylon Tea Plantations Company have sent round a circular to its shareholders, convening a meeting for the 6th January next, "to explain fully the reasons which influence them in extending their interests to the Malay Peninsula." Mr. Talbot has reported that during his visit he saw much of the country and visited many of the coffee estates in Perak and Selangor. After mature consideration, he reports that the cultivation of coffee yields results which would warrant his Company in extending its operations into the Straits Settlements, and that the results would materially add to the Company's prosperity. The circular above referred to states that the Company has a force in Ceylon of 6,000 coolies, and a number of superintendents who are well versed in coffee cultivation and are in touch with the labour supply of Southern India; and as the want of labour appears to be the only difficulty felt by the coffee planters of the Straits, the Company would be able to work without experiencing

this disability to any very great extent. The Straits Government, it is added, would be willing to give every aid in the acquirement of land as well as in every other way. Careful experiments are to be begun on a small scale before committing the shareholders to any large expenditure. I confess that for myself, having in memory how Ceylon suffered in reputation owing to the Ceylon Company having had connexion with the Mauritius, I view with some dislike the notion of the "Ceylon Tea Plantations Company" commencing enterprise in another colony without some modification of the name by which it is so generally known.

The *Grocer* of the 12th inst. had a long article on "Ceylon Tea." The first part of it dealt with figures illustrative of the progress it has made in the home market as compared with Chinese and Indian teas. It estimates the shipments to reach the United Kingdom this year at 64 millions lb. The article reiterates the complaint "that among the importations of Ceylon tea this year there have been numerous samples of complete rubbish, which would not have been received by the trade as tea in the smallest sense, if they had been offered as invoices or breaks of Indian or China, and it is the magical name of Ceylon alone that has enabled importers to dispose of the said tea." It finds an explanation of these miserable imports in the continued rains experienced in Ceylon this year. Expectations are entertained, according to the writer, that this cause will not again often operate. Stocks are stated to be excessive, and the view is expressed that until these are worked down "quotations generally may be reckoned to rule as much as ever in favour of both retailers and consumers."

At the half-yearly meeting of the British North Borneo Company held this week, it was announced that Sir Rutherford Alcock, in consequence of his declining strength and advanced age, had decided upon retiring from his more active management of the Company's affairs. The news received from Borneo was declared to be tolerably satisfactory; but the land sales had almost ceased, partly owing to general financial depression, but mainly to the crisis which had overtaken the tobacco trade of the East. The production of this article in Sumatra alone has risen from 690 bales in 1868 to 236,323 bales sold this year, and the price had fallen to 72½ cents per half-kilo, or about one pound. Two important companies in connexion with Borneo had to liquidate, and the island generally had suffered much from the late bad times. The President made the following allusion to the capacity of their lands for coffee cultivation, observing that "coffee planting was increasing, and an expert who had had considerable experience in Ceylon, was about to visit and report upon the company's territory with a view of drawing attention to the capabilities of the soil for coffee, cacao, and tea."

Several of the Indian Tea Companies have declared their interim dividends during the week. Thus the Brahmaputra Tea Company declares such a dividend of 8 per cent for the half year at the rate of 16 per cent per annum. The Jorehaut Tea Company announces that the crop of 1891 has amounted to 1,612,000 lb. of packed tea, being an increase of 150,000 lb. over that of 1890, and that 100,000 lb. have been sold at an average price of 90½d per lb., or about ¾d per lb. over last year for a similar quantity. The directors of the Assam Company also recommend an interim dividend of 2½ per cent, or 10s per share, payable on January 1, and the Majuli Tea and Attaree Khat Tea Companies (Limited) have declared interim dividends of 2½ per cent on the working of current season, both payable forthwith.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, Dec. 5th.

CINCHONA.—Tuesday's bark auctions were of fair size as regards the number of packages offered; but the total weight of bark was not considerable, many of the packages being below average weight. The catalogues comprised:—

	Packages.	Packages.
Ceylon...	826 of which	731 were sold
East Indian ...	235 "	228 "
Java ...	238 "	238 "
South American	853 "	216 "
African ...	169 "	169 "
	1,471	1,612

Holdings seemed rather anxious to sell, and there was no very lively competition among the buyers, two or three agents only participating seriously. The average quantity of the barks was fairly good, and the samples shown comprised several nice lots of Suddrabas and a fair proportion of good grey bark. Yellow barks of eastern growth were scarce, but South American Callisayas were well represented. A parcel of 472 packages Nelligerry bark, which would have added greatly to the interest of the auctions, was withdrawn at the last moment. The result of the auctions was hardly satisfactory, and prices must be pronounced slightly easier, the average unit being barely 1 1-16ths d. per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works...	141,637
Messrs. Howards & Sons ...	13,071
Agents for the Italian and American works ...	37,368
" French works ...	31,505
" Anertach works ...	21,145
" Frankfort o/M and Stuttgart works	10,670
" Brunswick works ...	7,600
Sundry druggists..	49,810

Total quantity of bark sold ... 369,864
Bought in or withdrawn... 69,270

Total quantity of bark offered ... 870,184

CINNAMON.—The last periodical auctions of the year were held on Monday, when 3,070 bales Ceylon cinnamon were offered, including an unusually large proportion of good and fine qualities. The demand was a fairly good one, over four-fifths of the supply finding buyers at steady prices for ordinary and medium grades, while good and fine varieties declined in value from 1d to 2d per lb., as compared with the previous auctions. The following prices were paid:—Fine to superior firsts 9d to 1s 3d; common to good ditto 6d to 8d per lb; seconds, ordinary to superior 6d to 1s per lb; thirds, ordinary to superior 6d to 11d per lb; fourths, common to superior 6d to 10d per lb. A quantity of unworried cinnamon sold at 8d to 7d per lb, broken at 6d to 6½d per lb, and about 200 bags quillings and cuttings at 4d to 6d per lb.

QUININE.—On Friday a second-hand holder accepted 9d per oz for a 10,000-oz parcel of German bulk, thus reducing the price ¾d per oz below the nominal quotation and bringing it down again to the "lowest on record" figure. Again, before the bark auctions, a fair quantity of second-hand German bulk quinine changed hands at 8d per oz. The total sales are estimated at 30,000 to 40,000 oz. Today it would not be so easy to buy at that figure.

COFFEE LAND, &C., IN PERAK.—From the report on Taiping District for October we quote as follows:—

During the month several planters from Ceylon, who were amongst the first ten applicants for the land offered on special terms in the Circular of the 22nd April 1891, visited the coffee estates in the district and inspected some of the land in the immediate neighbourhood of Kuala Kangsar, with a view to making selections here. They seemed best satisfied with the land at Kamaning, but appeared to think that most of it that was worth having was included in the Liberian coffee estate of Mr. Hill. I am informed, however, that Mr. Buchanan, who was amongst those that visited this district, has decided to take up a block along the road between Kamaning and Ipoh. The following day I accompanied the Collector and Magistrate to Tronok, which is now the principal of the Blanja mining villages. Although mining has only been commenced comparatively recently, there are already a large number of Chinese in the locality, and there appears to be every promise of its turning out an important mining district.

THE PERUVIAN CORPORATION AND THE PROSPECTS OF PERU BECOMING A GREAT COFFEE, CACAO, RUBBER AND VANILLA GROWING COUNTRY.

Calling on Sir Alfred Dent at his Old Broad Street office, I was very kindly received and told a good deal about the mission of Messrs. Ross and Sinclair and the object of the Peruvian Corporation. The full results of the mission cannot be known till the formal reports are sent in; but already enough is known to show there is no reason why Peru should not become a great exporter of coffee, cacao, rubber and vanilla—all four plants, as I understood, being reported to be growing well; while the soil is described as very rich, and the climate most delightful. There remain the two necessary elements of success—labour supply and means of transport. As regards the latter, there are admirable, even wonderful railway lines penetrating through much of the country to be occupied, and it is upon those lines that the Peruvian Corporation would wish to see the produce thrown, because of their own property in the railways. I mentioned how, from the eastern slopes and valleys of the Andes, probably the Amazon and its branches would offer a ready and cheap means of transport by steamers, and how successful the Amazon Steam Navigation Co. (under my friend Capt. Hudson) had been in developing trade in these regions. "We have no desire," said Sir Alfred Dent, "to throw Peruvian trade on to the Amazon; we should rather bring grist to our own mill as owners of the railway system; but the Corporation are, of course, ready and anxious to encourage planting settlers and to sell land to them, and if any of these, eastward of the Andes, preferred to use the Amazon steamers rather than railways, there could be no objection." It is quite likely that Peru may attract some of our Ceylon planters, and of the capitalists interested in coffee in the East; for in respect of our old staple, as well as cacao and rubber, there can be no question of the splendid market now offering, nor of the prospect of a steady demand; while no one would dream of going with money or planting experience to Brazil in those unsettled times. It is quite possible that we may see a falling-off, if not partial collapse of Brazilian exports, if the civil war, now threatening in several provinces, breaks out. In that case there would certainly be the greatest encouragement to go to Peru for coffee. If it be true that the shrub has run wild there and is freely encountered, a first step of the corporation, one would think, would be to establish an agency to buy all the coffee that can be made available by the Peruvians from existing gardens or from jungle patches. As respects labour supply, Sir Alfred Dent seemed to consider that as 2,000 to 3,000 "navvies" for railway work could readily be collected at any time in Peru, there could not be much difficulty in getting some to plant and pluck coffee. But I did not fail to point out the difference, more especially in what could be paid for railway men as compared with the wages for plantation labour. However, from another quarter I learn that Mr. Ross has no fear about suitable labour being available on the spot, so that there must be satisfactory work to be got of native-born Peruvians in some shape. I am promised an interview with Mr. Ollard, the manager of the Corporation, when all available papers up to date will be placed at my disposal; meantime on the chance that a copy of the full report of the Corporation directors presented to the shareholders at their meeting on the 3rd instant has

not reached you, I send the copy handed to me by Sir Alfred Dent. It will be seen from this that "The Peruvian Corporation, Limited," had about £4,197,713 of capital in the four principal railways in Peru (£1,102,187 of capital being held by other persons), that it is interested in other lines at present leased, and also in steamers which navigate Lake Titicaca and the river Desaguadero. Other schemes are on foot for railway extension into Bolivia. Then in "guano" so large is the interest of the Corporation that "a contract for the sale of 300,000 tons has recently been entered into on favorable terms with Messrs. Antony Gibbs & Sons," while there are claims on Chili and valuable mines' concessions among the assets. Altogether the capital raised and invested by the Corporation exceeds 17½ millions sterling! But I have yet to notice the part of the report, and operations of the Company, of most interest to Ceylon readers—that under the head of "Land." In the accounts the only item bearing on it is entered as "Land Exploration £2,492 18s 0d" which may be supposed to be the cost of the mission just completed, or it may refer to the earlier Spanish mission. In any case, you will want (if you have not done so already) to reprint the whole of the portion of the report referring to "Land." It is as follows:—

LAND.

The data collected and received by the Corporation in reference to the land in the interior of Peru, on the eastern side of the Andes, point to the Central district as being the most suitable for more immediate colonization.

By the Central district is meant the land layug between Oroya, on the Central Railway, and the river Ucayali, and by opening up this district it is thought that a large area could be brought into communication with the coast, and the produce of the interior collected and brought down by the Central Railway.

With the object of effecting a settlement in this district, a commission, including three Spaniards practically acquainted with agriculture, was sent to Peru, and they made an expedition into the Central district, visiting, besides other localities, the valley of Chanchamayo and the lands adjacent to the Rivers Ene and Perene.

The following are extracts from their Reports as translated:

A careful examination of the cultivated lands from Chanchamayo to San Luis de Shuaro, shows the immense wealth of produce notwithstanding the want of labour, which is also a reason why other produce which might constitute immense wealth is not cultivated; because plants growing wild, as is the case in many parts of these regions, would produce much more if cultivated for instance, the indigo plant, the vanilla, cacao, cotton, caoutchouc tree, and many others, which can only be grown in these zones.

All these lands are broken, but very good plains are met with, and generally the lands are very healthy. The temperature is from 25 to 30 degrees centigrade (77 to 86 Fahrenheit), and elevation above the level of the sea is from 2,000 to 3,000 feet. There are no natural pastures, for which reason cattle cannot be raised on a large scale.

The products which constitute the actual wealth are as follows:—

SUGAR CANE.—The growth of this plant is extraordinary, and it is cut as often as twenty times. At present it is used for the manufacture of rum and alcohol, on account of their large consumption and good prices; each "arroba" (25 lb.) on the estate being worth 7 soles.

COFFEE.—The coffee plant grows with great rapidity and begins to give fruit in two years, and produces to its full in the third or fourth year. Each plant gives on an average from 8 to 10 pounds gross; the consumption is very large, and the produce is worth 18 or 20 soles the quintal. The plant bears for twenty or thirty years.

YUCA.—Multiplies in a prodigious manner, it is greatly appreciated, and is indispensable. It is gathered at the tenth month, and each plant generally gives an "arroba," worth 4 reales (say 1s 2d).

MAIZE.—Grows with credible rapidity, and three crops a year can be obtained. This plant constitutes the general fodder for all domestic animals. It yields abundantly, and two quintals are worth 5 to 6 soles.

FREJOLAS (Beans).—Like maize grow rapidly, and the crop matures in 40 days. It is worth 4 soles per quintal.

RICE.—Is easily grown without irrigation; two crops a year are obtained, and it is the article in greatest demand. Its value is one sol per "arroba."

COCA produces very well. It is the article most appreciated in the whole of the mountain districts, and is worth 8 soles per "arroba."

To these must be added all classes of vegetables which grow well, such as various sorts of potatoes, cabbages, tomatoes, lettuce, mani (pea nut), ome to (sweet potato), and the following fruit—melons, water melons, oranges, lmons, pines, plantain tree, "paltas" (Avocat pear tree), chirimoya (custard apple), papaya, guava trees, figs and grapes.

All those we saw as far as San Luis, up to which point the lands already under cultivation reach. None of these products require artificial irrigation, nature having done all that was wanted.

From San Luis de Suan to the River Eñenas and its confluence with the Perené, the greater part of the land is wooded, and is inhabited by Indians, Amnyses, and Campas tribes, although in small number. At times two or three leagues, may be covered without anyone being met. These Indians are docile and intelligent, and the Campas tribe is believed to be numerous. We believe that they cannot be prejudicial but, on the contrary, must be useful to a colony such as we contemplate.

These lands in our opinion offer to a colony a flattering future, by reason of the fertility of the soil, the many fine water-courses which intersect them in all directions, and, above all, on account of the climate. The temperature at Metrano is 22 degrees centigrade (72 Fahrenheit) and the elevation above the level to the sea is 4,000 feet.

The following is the description of these lands: Leaving San Luis on the right, and on the banks of the river Puiñas at about two or three leagues from that point, a fine pampa is met with of about two leagues in length, with small undulations declining to the south, and many water-courses having a sufficient quantity of water to work a factory. On this pampa are all classes of trees of the most exquisite wood, such as cedar, walnut, mabogany, gum trees, jacaranda, obonta, pucheri, cascarilla (Peruvian bark), oak of different classes, and above all the oantohoue (india rubber), which if cultivated would bring immediate profit.

Here are found wild the indigo tree, vanilla, cotton, and vegetable ivory in great abundance; and it is believed that in these regions all classes of plants may be grown.

From this point and leaving Metrano for the river Eñenas large "pajonales" (grass plains) are met with, giving good and abundant pasturage for the rearing of sheep, cattle, and goats; and it may be believed that on these heights corn and other cereals can be produced, if not on a large scale, at least in sufficient quantity for the requirements of the Colony; and we may hope the same with regard to the vine.

Vegetation is so varied and abundant that only a visit to these places can give any idea of what they contain. Here are met with mines of salt, which some day may have great importance, and mines of very good iron and copper, not being worked at present.

Another expedition has been dispatched, consisting of Messrs. Ross and Sinclair, two well-known Ceylon planters. The primary object of this expedition is to ascertain if the cultivation of coffee, tea, and other tropical products could be undertaken on a commercial basis; but they will report generally on all the land they visit. Their report has not yet been received, but in the meantime it may be interesting to quote a shortly from a letter written by one of them, his general view of the country. He writes: "One has to modify

their preconceived notions of the tropics after a sojourn in this peculiar country I have hitherto, for instance thought that European emigrants—as labourers—were wholly unsuited for the tropics. This does not apply to Peru. Whatever difficulties may exist as regards transport or intercommunication, there can be no reasonable doubt that this vast region offers a field for colonization such as can be found in few other parts of the world. It is not merely the marvellous productiveness of the soil that calls for admiration, but the variety and healthfulness of the climate that seems so much to surpass that of any other country I have ever come across. In the pure tropical temperature, such as we experienced amidst the moist luxuriance of the Perené Valley, it may be, and is possible, by unvented exposure to contract fever, but taken as a whole, I do not believe there is a healthier climate under the sun than Peru, and it is impossible to think of any race of human beings who might not find a congenial home here, and whose chance of longevity might not be increased by a residence in one or other of the various localities."

Mr. P. D. G. Clarke, of the Government Gardens, Ceylon, accompanied this expedition to the banks of the Perené, and the information he brings confirms that received from Messrs. Ross and Sinclair, to the effect that the lands in that district are suitable for every kind of cultivation and that most of the valuable products, such as coffee, cocoa, vanilla and india rubber are found in a wild state.

The results of these investigations show, so far, that there is an immense field for planting and settlement, but that the want of railway communication is very seriously felt. The board has decided to take no definite action for the settlement of any part of this district until the Central Railway is opened to Orya, and until the hereafter-mentioned survey through the district has been made. Meanwhile application has already been made to the Government for a grant of land in this district, and they have allocated 600,000 hectares out of which the Corporation is entitled to select 500,000 hectares (1,250,000 acres).

Under an agreement dated 28th January, 1890 with the Government of Peru, the Corporation has the right to build a Railway to one of the navigable rivers in the Amazonian Provinces, and is entitled to receive an allotment of 8,000 hectares (15,000 acres) of unappropriated land for each kilometre of railway constructed. The Corporation in turn is obliged to send an expedition to locate the most suitable route for this Railway, but the building of the line is entirely optional. Instructions have been sent to Lima for the necessary expedition to be dispatched in the early part of next year, and, it being a matter of almost national importance to Peru to open up the whole of the Central district, the Corporation hopes that special inducements will be offered to them by the Peruvian Government to build this Railway.

It is to be hoped that the Corporation will not help in what threatens to be "the overproduction of tea" and I must try and put in a word to that end. In coffee and the other products mentioned, there is plenty of scope and great encouragement to cultivation. The report of the Spaniards evidently carried little weight in "the City" or in England whereas that of "the Ceylon planters" is eagerly and trustfully anticipated. It is a great compliment, of course to Ceylon which is now more than ever recognized as the best nursery for tropical planters; I trust Messrs. Sinclair and Ross may arrive, as expected, about the 13th January in good health and spirits.

SUGAR CULTIVATION IN THE SANDWICH ISLANDS, encouraged by exceptional United States laws, has assumed such importance that seven pages of the Honolulu "Planters' Monthly" are occupied with a directory of persons employed on the plantations.

PROSPECTS OF COFFEE CULTIVATION IN THE MALAY PENINSULA.

Our readers will be interested in the information contained in the following article, the latest and most authentic which is available.

The cultivation of coffee at the present moment holds out such promises of substantial—not to say immense—returns as it has never done before, and without doubt is far and away the most profitable of all agricultural pursuits when carried on in a country where leaf disease and green bug are either altogether absent—or kept in check by climate influences so as to have but little effect and on the permanent and regular production of crop. In Brazil the only flourishing coffee districts of any extent are now existent—but there are many influences at work in that country which will counteract all efforts to increase the production and export. The exports from the older districts are falling off rapidly in consequence of the abandonment of the estates, whilst the cultivation is extending in the newer districts of the interior. The emancipation of the slaves was a great blow to the cultivators of coffee, the revolution which followed and the commercial crisis, which embarrassed the relations between the planters and the banks, was an additional disaster; and now that the country is fast drifting into a state of anarchy we may safely prognosticate a decline in the exports which cannot fail to leave its effect in a very marked degree on the European and American markets. Already we hear of a shrinkage of the present crop to the extent of a million or so of bags below the estimate—and an anticipated deficient crop for the following season. The extension of railways into the new coffee districts—as well as the extension of cultivation in the districts where railways already existed—has had the same effect in Brazil as it had in a small way in Ceylon when our railway was opened. The upcountry crops which in former years had reached Colombo by slow degrees in bullock carts, then came down by rail with such a rush that the Colombo stores were choked—and curing operations could not be carried out fast enough to meet the demands of the season. It has been the same in the Brazil,—and exaggerated estimates were formed of the total crops in consequence of so many thousand bags reaching the seaports in excess of the usual daily receipts.

But whether or no the crops of Brazil continue to be produced in the present—or even very largely increased—amount, all the better qualities of coffee, known as "East Indian," cannot fail for many years to command very high prices in the London market. Just now the market being almost bare of such coffees we find the first poor pickings of Ceylon crops fetching extreme rates and beings in great demand. For want of something better Liberian coffee, prepared in the way with which, we have always been accustomed to deal with Arabian, is also fetching good prices—and the cultivation in the Straits and other places is a very profitable one. But what is wanted is good washed and well cleaned Arabian coffee; and the production of it in any appreciable quantity cannot fail to be extremely remunerative.

The administration of the protected States of Perak and Selangor is very wisely bestirring itself to secure the advantages accruing from an industry which holds out such promises as coffee does at the present day.
